At the annual meeting of the Société d'Hypnologie held in Paris on the 11th inst., M. Bérillon stated as the result of his experience in the treatment of six cases that complete demorphinisation can, in the majority of instances, be obtained by means of hypnotic suggestion without isolation in a special establishment. The difficulty of attaining this end is not, as might *a priori* be imagined, proportional to the amount of the daily dose of the drug to which the morphinomanic had accustomed himself. Old offenders who have been in the habit of administering to themselves considerable doses are sometimes, according to M. Bérillon, more easily curable than those accustomed to smaller doses. In those exceptional cases where isolation is necessary recovery is more rapid and easy when psycho-therapeutics are had recourse to, such means diminishing notably the pain and physical and mental discomforts entailed by abstinence from the poison. The average duration of the suggestion treatment is one month. The supply of morphia should be gradually diminished. When this gradual reduction has brought the daily dose down to a few centigrammes complete suppression should be insisted on. The suggestion *séances* should be more frequently repeated during the week following complete suppression. The prognosis after cure by hypnotic suggestion is much better than when abstinence from morphine has been brought about by other methods, it being easy to inspire the patient with disgust for the habit by psychical means.

#### *The Consumption of Tarlatan in the Paris Hospitals.*

Calico bandages have long ago become things of the past in the surgical wards of Paris hospitals, that stuff having been dethroned by tarlatan. An idea of the expense entailed by these liberally applied tarlatan bandages may be gathered from the fact that there were used in the Paris hospitals during the year 1890 no less than 1600 kilometres, or 1000 miles, of this material. In 1891 the mileage had reached 1188, an amount which cost 135,000 fr., or £5600.

#### *Cholera in Paris.*

From the means of information within my reach I gather that the cholera epidemic remains stationary and exhibits no tendency to extension, at any rate within the fortifications. On Friday last there occurred at Aubervilliers three deaths and at Clichy, in a filthy house inhabited by rag-pickers, two persons died. Several non-fatal cases occurred at Gennevilliers. From the 14th to the morning of the 16th eighteen deaths occurred in the northern suburbs, comprising principally St. Denis, St. Ouen and Aubervilliers. No new case was reported in Paris itself on Saturday, nor did any suspicious death occur on Sunday. Ten fatal cases were reported from the above-mentioned suburbs and one from Clichy. On Sunday Aubervilliers was visited by Drs. Proust and Dujardin-Beaumont, their colleague on the Council d'Hygiène, Dr. Léon Colin, repairing to St. Denis. The special Sanitary Commission, accompanied by the Prefect of Police, inspected the rag-pickers' house at Clichy mentioned above and ordered its immediate evacuation. From Clichy the Commission extended its peregrinations to Levallois-Perret and Asnières. News received this morning at the Prefecture of Police announced an improvement in the sanitary situation in the north-west suburbs, only two new cases being reported. At St. Denis Hospital forty-nine cases have up to the present been under treatment, a third of whom are cured, the rest having either died or being convalescent. At St. Ouen the distribution of filtered water produced an immediate improvement. Here the schools have all been provided with filters. Things are better also at Aubervilliers, where filters

will be shortly installed. An old disused artesian well has been repaired and is extensively patronised. There is no case at Levallois-Perret, but the malady reigns at Asnières. Officially the disease is still dubbed *épidémie oholériforme*.

Paris, July 20th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *The Sixty-fifth Meeting of the Society of German Naturalists and Medical Men.*

THE sixty-fifth meeting of the Society of German Naturalists and Medical Men will be held at Nuremberg in the middle of September. The programme is as follows:—Sept. 12: A general meeting in the hall of the Gymnastic Club; a lecture by Professor His of Leipsic on the Structure of the Nervous System; a lecture by Professor Pfoffer of Leipsic on the Sensibility of Plants; a lecture by Professor Hensen of Kiel on the Expedition of the Humboldt Trust; at 8 P.M. a social gathering in the restaurant of the Stadtpark, at the invitation of the municipality of Nuremberg. Sept. 13th: Sectional meetings; excursions; at 8 P.M. a meeting in the rooms of the Museum Society. Sept. 14th: A general meeting in the Gymnastic Hall; a lecture by Professor von Helmholtz on Permanent Forms of Motion and Apparent Substances; a lecture by Professor Strümpell of Erlangen on the Alcohol Question; a lecture by Professor Ziegler of Freiburg, on the Nature and Importance of Inflammation; at 5 P.M. a banquet in the Gasthof zum Strauss. Sept. 15th: Sectional meetings; at 8 P.M. a ball in the Gasthof zum Strauss. Sept. 16th: A general meeting; a lecture by Professor Günther of Munich on Volcanic Phenomena regarded from the Physical and Geographical Points of View; a lecture by Professor Hieppe of Prague on the Etiology of Infectious Diseases and their Relations to the Development of the Causal Problem; at 3 P.M. an inspection of industrial establishments; at 8 P.M. a social gathering in the festal illuminated park of the Rosenau Society. Sept. 17th: An excursion to Rothenburg. A ladies' committee will show the ladies the sights of the city and provide for their entertainment during the meetings.

#### *Dr. Behring on Blood-serum Therapeutics.*

Dr. Behring of Koch's Institute for Infectious Diseases, well known for his studies on immunity against traumatic tetanus and diphtheria, has published a treatise on the practical aims of blood-serum therapeutics and the methods of producing immunity, in order to obtain medicinal serum. He endeavours to prove that the blood-serum of animals rendered immune by treatment with cultivations acted on by trichloride of iodine cures other animals infected by the disease and renders healthy ones immune. He has applied this method with success against traumatic tetanus and diphtheria, and now states that one of his fellow-labourers has been equally successful in diseases caused by streptococci. All these results have been obtained by experiments on animals, but Behring's final aim is to find a new means of combating diphtheria, tetanus, &c., in the human body, and he indicates the way to that great end, admitting, however, that it is a difficult and especially a very costly one—too costly for individual investigators or even institutions to enter on without ample pecuniary aid. In the second part of his treatise he criticises other methods of producing immunity. The treatise is published by Thieme of Leipzig, and its title is "Die praktischen Ziele der Blutserum-Therapie und die Immunisirungs methoden zum Zweck der Gewinnung von Heilserum."

#### *The Cholera.*

In the semi-official *Norddeutsche Allgemeine Zeitung* (North German General Gazette) of the 14th inst. is the following paragraph:—"The information received here from Asia and European Russia leaves no room for doubt that we must be prepared for a further spread of cholera from the East. But now news has arrived from the West which indicates the possibility of an outbreak of that disease beyond our western frontier also. Public opinion in Germany has not yet been rendered uneasy by these statements, and this is right, for the population may rest assured—just as on the occasion of the last epidemics, which fortunately affected Germany little, if at all—in the consciousness that the Imperial Government and the authorities in the frontier districts of the individual states of the Empire are

following the course of the pestilence with attention, and have prepared for all the measures that will be necessary should the disease appear in our vicinity, though it is hoped it will not."

*Dr. Otto Völker.*

Dr. Otto Völker, head of the surgical department of the Ducal Hospital at Brunswick, died suddenly of heart disease at the bedside of a patient at Harzburg on the 10th instant, aged forty-nine. He was the author of essays on the Diseases of the Lateral Cervical Region, on Cartilaginous and Osseous Loose Bodies in Joints, &c., and contributed largely to the *Zeitschrift für Chirurgie* and to *Virchow and Hirsch's Jahresbericht über die Leistungen in der Medizin*.

#### Miscellaneous Items.

Professor Henoch celebrated his seventy-second birthday, which was also the fiftieth anniversary of his graduation, on the 16th inst. The Emperor bestowed on him the Order of the Red Eagle of the Second Class.

At the instance of Professor Förster, Rector of Berlin University, a meeting of professors and students will be held on the 22nd inst. in the Philharmonic Hall, to do honour to the memory of Professor von Hofmann.

A monument of the late Professor von Nussbaum was unveiled at Munich on the 16th inst., prince and people uniting to do him honour.

Professor Hilger of Erlangen has been appointed to succeed Professor Buchner (who retires at the end of this session) as professor of pharmaceutical chemistry and director of the Pharmaceutical Institute at Munich. Buchner has filled the chair in question since 1852.

The number of summer visitors at Ems in the first days after the beginning of the Prussian school holidays (from the 9th to the 12th inst.) was 9290; at Marienbad 8461; at Franzensbad 4184; at Heligoland 2390; at Neundorf 971; and at Sulza 895.

Berlin, July 18th.

## MEDICAL TRIAL.

### HIGH COURT OF JUSTICE, QUEEN'S BENCH DIVISION.

#### MACDONALD v. TURNER.

##### THE PURCHASE OF A MEDICAL PRACTICE.

THE case of Macdonald v. Turner was heard in the Queen's Bench Division on July 19th before Mr. Justice Wright. Both parties to the action are medical men, who entered into communication in consequence of an advertisement which appeared in our columns of a medical practice which was represented as returning an income of about £600 a year. Plaintiff asserted that after a three months' trial, during which time he used every endeavour to make the business a success, it had only produced the sum of £20, and for that period he paid in respect of his tenancy £28. Defendant's avowed reason for giving up the practice was that he had disease of the hip, which would require an operation, and that the practice was suffering in consequence of his inability to attend to it. In the course of conversation he told plaintiff that he could not guarantee figures, but he gave him every opportunity of inspecting the books. Mr. Justice Wright said he did not think there had been any wilful misrepresentation, though no doubt there had been exaggeration. Mr. Hopkinson submitted that even innocent misrepresentation would entitle the plaintiff to recover. Mr. Rowlandson stated that he had evidence that there was no misrepresentation of any kind whatever. Mr. Justice Wright said that he would hear that question of law argued on Thursday next.

**FIRST AID.**—The Duchess of Albany distributed on the 13th inst. the certificates gained by the most successful students of the Streatham local centre of the St. John Ambulance Association. During the winter months one nursing class and six first-aid classes were held and were attended by twenty-seven men and 125 women, to seventy-seven of whom certificates of proficiency were granted. Of the ladies, sixteen gained certificates for nursing and fifty-five for first aid. Ten certificates for first aid were awarded to men.

## Medical News.

**THE ITALIAN HOSPITAL IN LONDON.**—By the permission of the committee of management of "Venice" at Olympia, a morning performance of that entertainment was given on Wednesday last in aid of the funds of the Italian Hospital in London.

**A COTTAGE HOSPITAL FOR DINAS POWIS.**—It is stated that a building situated near the railway station has been taken for the purposes of a cottage hospital for Dinas Powis and that a lady resident in the village had consented to assume the charge of the institution when opened.

**NEW INFIRMARY FOR ISLINGTON.**—The difficulties which the Islington guardians have hitherto had to contend against for providing a new infirmary are apparently likely to be surmounted. They have just resolved to offer £17,000 for five acres of ground in Tollington-park and to erect thereon a building to provide about 800 beds at an outlay of from £80,000 to £85,000. The entire cost of the undertaking is estimated at £110,000.

**FATAL LEAD POISONING AT LOW MOOR.**—At an inquest held at Low Moor last week on the body of a forgerman a verdict was returned to the effect that the deceased had died from lead poisoning, epilepsy and exhaustion, and that the lead poisoning was caused by drinking water supplied to the inhabitants by the North Bierley Local Board and purchased by that board from the Bradford Corporation, such water having a solvent action upon lead.

**ST. JOHN AMBULANCE ASSOCIATION.**—The practical application of ambulance work finds a strong centre at Ramsgate. Through the persevering energy of the local honorary secretary, assisted by three surgeons, Messrs. Cotton, Tamplin and Berry, not only has a corps of men been formed who are frequently called for accidents and removals, but there is at the same time a small but efficient corps of some eight or twelve lady nurses who devote their time in supplying gratuitous nursing to the sick poor in their own homes. Both these corps have now been working for more than a year and are thoroughly appreciated both by the medical men and the patients. On Saturday afternoon last a pleasing function took place at the house of the honorary secretary in the presentation of a testimonial to the surgeon, Mr. Cotton, who has instructed most of the ladies' classes and is honorary surgeon to the nursing corps.

**ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.**—The fourth quarterly meeting of the session will be held on Tuesday, Aug. 2nd, in the Anatomical Theatre of the new buildings of the University of Edinburgh, at 4.30 P.M. Agenda:—Exhibits—Professor Sir William Turner, F.R.S.: 1. A series of Specimens. Dr. Symington: 2. (a) A Human Heart, with Unusual Arrangement of the Anterior Papillary Muscle; (b) Specimen illustrative of the Mode of Closure of the Ileo-cæcal Valve. Papers—Professor Cleland: 3. A Contribution to the Comparative Anatomy of the Ankle-joint. Dr. Birmingham: 4. (a) Extreme Anomaly of Heart, with History; (b) Spina Bifida, with Abnormality of Skull. Dr. Musgrove: 5. (a) The Costo-sternal Articulations; (b) The Bloodvessels and Lymphatics of the Retina (with lantern slides). Dr. Symington: 6. A Note on the Fascia Dentata in the Human Brain.

**ROYAL COLLEGE OF SURGEONS IN IRELAND.**—The following prizes have recently been awarded:—Operative Surgery: Mr. G. Hamilton, 1st Prize (Gold Medal); Mr. O. W. Elsner and Mr. T. C. Perry (equal), 2nd Prize (Silver Medals); Mr. H. G. Lo Fanu and Mr. F. Warren (equal), 3rd Prize (Certificates). Practical Chemistry: Mr. H. E. Eardley, 1st Prize (£3 and Medal); Mr. H. F. Conyngnam, 2nd Prize (£1 and Certificate). Practical Histology: Mr. E. A. Mecke, 1st Prize (£3 and Medal); Mr. E. C. Hodgson, 2nd Prize (£1 and Certificate). Materia Medica: Mr. E. T. Moore, 1st Prize (£3 and Medal); Mr. E. A. Mecke, 2nd Prize (£1 and Certificate). Pharmacy: Mr. R. M. Hamilton, 1st Prize (£3 and Medal); Mr. H. B. S. Montgomery, 2nd Prize (£1 and Certificate). Medical Jurisprudence: Mr. T. T. O'Donnell, 1st Prize (£3 and Medal); Mr. L. F. Corbet, 2nd Prize (£1 and Certificate). The "Mayne Scholarship" of £15 has been awarded to Mr. G. Hamilton.

**THE LONDON COUNTY COUNCIL AND THE WATER-SUPPLY.**—At the usual meeting of the Council on Tuesday last it was agreed that, subject to an estimate being submitted to the finance committee, the Council should contribute a further sum of £250 towards the expenses of the investigations now being carried on by Dr. Percy Franklin and Professor Marshall Ward at the Royal Society into the question of the vitality of microscopic pathogenic organisms in water.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

**BANNATYNE, GILBERT A., M.D. Glasg.**, has been appointed Honorary Medical Officer to the Bath Royal United Hospital.  
**CARNELLEY, M., L.R.C.P. Lond., M.R.C.S.**, has been appointed Medical Officer for the Gotham Sanitary District of the Basford Union.  
**CAUDWELL, H., L.R.C.P., L.R.C.S. Edin.**, has been appointed Medical Officer for the Woodstock (No. 2) Sanitary District of the Woodstock Union.  
**CROOM, J. H., M.D., F.R.C.P., F.R.C.S. Edin.**, has been appointed Physician to the Edinburgh Royal Maternity and Simpson Memorial Hospital.  
**DRUMMOND, W. B., M.B., C.M. Edin.**, has been appointed Resident Physician to the Royal Edinburgh Hospital for Sick Children.  
**FRAZER, E. E., M.R.C.S., L.R.C.P., L.S.A.**, has been appointed House Surgeon to the Royal United Hospital, Bath, vice L. H. Walsh.  
**HARDY, C. M., M.B. Durh., B.S.**, has been reappointed Medical Officer of Health for the Rural Sanitary Authority, Darlington.  
**HARRIS, A. E., L.R.C.P., L.R.C.S. Edin.**, has been appointed Medical Officer of Health for Islington, vice Tidy, deceased.  
**HILL, WALTER J., M.R.C.S., L.R.C.P.**, has been appointed House Surgeon to the Bristol Royal Infirmary.  
**INCE, W. H., Ph.D. Würzburg**, has been appointed Demonstrator of Physics and Chemistry in the Medical School of St. Thomas's Hospital.  
**LUCAS, ALBERT, L.R.C.P. Lond., F.R.C.S.**, has been appointed Resident Surgical Officer, General Hospital, Birmingham, vice Holden, resigned.  
**MARCH, G. C., L.R.C.P. Lond., M.R.C.S.**, has been appointed Medical Officer for the Gosforth Sanitary District of the Whitehaven Union.  
**MCDONNELL, M. S., M.R.C.S.**, has been appointed Medical Officer for the First Sanitary District of the Southampton Incorporation.  
**NUTT, H., M.R.C.S.**, has been appointed Medical Examiner on the Society's Staff by the Equitable Life Assurance Society of the United States for the Sherborne, Dorset, District.  
**ORMEROD, HENRY LAWRENCE, M.R.C.S., L.R.C.P.**, has been appointed House Physician to the Bristol Royal Infirmary.  
**ROBERTSON, W. FORD, M.B., C.M. Edin.**, has been appointed Resident Physician to the Royal Edinburgh Hospital for Sick Children.  
**STREETEN, F. E., L.R.C.P. Edin., M.R.C.S., D.P.H. Irel.**, has been appointed Medical Officer of Health for the Rural Sanitary District of the Farrington Union.  
**SYRETT, FRANK**, has been appointed Resident Medical Officer to the Children's Hospital, Newcastle-on-Tyne.  
**VERNON, H., L.S.A.**, has been appointed Assistant Medical Superintendent of the Infirmary, Parish of Paddington.  
**WALSH, L. H., M.R.C.S., L.R.C.P., L.S.A.**, has been appointed Resident Medical Officer to the Royal United Hospital, Bath, vice E. H. Biddlacombe, resigned.  
**WATSON, J., M.B. Durh., F.R.C.S. Edin., L.R.C.P. Lond.**, has been appointed House Physician to the Wolverhampton and Staffordshire General Hospital.  
**WILLIAMS, T. O., L.R.C.P., L.R.C.S. Irel.**, has been appointed Medical Officer for the Third Anglesey Sanitary District of the Bangor and Beaumaris Union.

## Vacancies.

*For further information regarding each vacancy reference should be made to the advertisement.*

**ANCOATS HOSPITAL, Manchester.**—Senior House Surgeon. Salary £80, with board and washing.  
**BRADFORD CHILDREN'S HOSPITAL.**—House Surgeon. Salary £70, with board, residence and washing.  
**BURY DISPENSARY HOSPITAL, Bury, Lancashire.**—Senior House Surgeon. Salary £100 per annum, with board, residence and attendance.  
**DEACONESSES' INSTITUTION AND HOSPITAL, Tottenham.**—Resident House Surgeon for one year. Salary £90 per annum.  
**GENERAL HOSPITAL, Birmingham.**—Two Assistant House Surgeons for six months. Residence, board and washing provided.  
**GREAT NORTHERN CENTRAL HOSPITAL, Holloway, N.**—House Surgeon. Salary £60 per annum, with board and lodging in the hospital.  
**HORTON INFIRMARY, Banbury.**—House Surgeon and Dispenser. Salary £60 per annum, with board and lodging.  
**LEEDS FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.**—Two Surgeons for the Bischoff House and Malton House Surgeries of this Association. Salaries £208 per annum and Midwifery fees. Good residence, drugs supplied, and rates and taxes paid. Also Assistant Surgeon. Salary to commence at £120 and Midwifery fees. (Apply to Mr. C. H. Wilson, 8, South Parade, Leeds.)

**LINCOLN ODDFELLOWS' MEDICAL INSTITUTE.**—A qualified Assistant. Salary £120 a year (out-door). (Apply to the Secretary, 12, North Parade, Lincoln.)  
**LIVERPOOL STANLEY HOSPITAL.**—Honorary Physician.  
**LIVERPOOL STANLEY HOSPITAL.**—Honorary Surgeon.  
**NOTTINGHAM BOROUGH ASYLUM.**—Resident Clinical Assistant for six months. Board and residence provided.  
**ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL, Portsea.**—Assistant House Surgeon for six months. Board, residence and washing, and an honorarium of £15 15s. at expiration of term of office.  
**ROYAL SOUTH HANTS INFIRMARY, Southampton.**—Assistant House Surgeon for six months. Board, residence and washing provided, and an honorarium of £10 10s., conditionally, at expiration of term of office.  
**ST. LUKE'S HOSPITAL.**—Resident Clinical Assistant for six months, with board and residence.  
**SHEFFIELD PUBLIC HOSPITAL AND DISPENSARY.**—Senior Assistant House Surgeon. Salary £65 per annum, with board, lodging and washing.  
**STOURPORT MEDICAL AID ASSOCIATION.**—Assistant (out-door). (Apply to Mr. John Bourne, Stourport.)  
**WEST KENT GENERAL HOSPITAL, Maidstone.**—House Surgeon. Salary £160 per annum, with furnished apartments, coals, gas and attendance in the hospital.

## Births, Marriages, and Deaths.

### BIRTHS.

**MAURICE.**—On July 17th, at Friar-street, Reading, the wife of William James Maurice, M.A., M.B. Oxon., of a son.  
**O'REILLY.**—On July 14th, at Thurnby, Guildford, the wife of Surgeon-Major J. O'Reilly, M.B., of a daughter.  
**PORTER.**—On July 19th, at Holsley, Yorkshire, the wife of J. Francis Porter, M.D., Coroner for County of Yorkshire, of a son.  
**PURVES.**—On July 16th, at Hardwicke Cottage, The Common, Wimbledon, the wife of W. Laidlaw Purves, M.D., of a son.  
**WELLS.**—On July 12th, at Belsize-park, the wife of Poulett Wells, M.B., of a son.

### MARRIAGES.

**GOODSALL—WRIGHT.**—On July 19th, at Holy Trinity Church, Lamorbey, Frederick Goodsall, M.D., to Edyth Elwin, eldest daughter of the Rev. John Wright, late Rector of Falmouth.  
**HUNTER—DAVIDSON.**—On July 18th, at the Presbyterian Church, Willesden, James Hunter, M.D., Dregthon, Ayrshire, to Sarah Jane (Minnie), eldest daughter of the late Dr. John Davidson, C.B., Inspector-General R.N.  
**KELLET—BARCLAY.**—On July 14th, at Moseley, by the Rev. F. Kellett, father of the bridegroom, assisted by the Rev. W. Wilson of Manchester, Alfred F. Kellett, M.B., B.S. Cantab., of Lewisham-road, Lewisham, S.E., to Margaret Eleanor (Nellie), second daughter of Thomas Barclay, of Arnccliffe, Moseley, Birmingham.  
**OWEN—HUGHES.**—On July 20th, at St. James the Less, Victoria Park, William Owen, Surgeon, Shore-road, South Hackney, to E. E. Hughes, widow of the late J. B. Hughes, Esq., Newport, Monmouthshire.  
**RICHARDS—PENNINGTON.**—On July 18th, at St. Oswald's Church, Collyhurst, Manchester, by the Rev. A. W. Taylor, M.A., Rector, Arthur Izod Richards, M.R.C.S., L.S.A., youngest son of the Rev. George Richards, D.D., Rector of Marlingford, Norfolk, to Florence May, youngest daughter of the late Dr. T. R. Pennington, of Pembroke-place, Liverpool. No cards.  
**RODGERS—BOWMAN.**—On July 18th, at St. Andrew's, Cambridge, by the Rev. H. Smith, J. H. Rodgers, L.R.C.P., L.R.C.S. Edin., Lincoln, to Florence E. Bowman, Darlington.  
**STAVELEY—NICHOL.**—On July 20th, at St. Mary Abbott's, Kensington, by the Rev. H. B. Nichol, brother of the bride, assisted by the Rev. the Hon. E. Carr Glyn, Vicar of Kensington, and the Rev. E. D. L. Harvey, Rector of Downham Market, W. H. C. Staveley, F.R.C.S., of 13, South Eaton-place, S.W., second son of the late T. G. Staveley, of the Foreign Office, to Annie Maud, third daughter of the late Dr. Nichol, of Denmark-hill, S.E., and Mrs. Nichol, of 15, Brunswick-gardens, Kensington, W.  
**THORNTON—CLIVE.**—On July 18th, at St. Mark's, North Audley-street, by the Hon. and Rev. Canon Bridgeman, uncle of the bride, assisted by the Right Rev. the Lord Bishop of Ripon and the Hon. and Very Rev. the Dean of Hereford, John Knowsley Thornton, of 22, Portman-street, and Hildersham Hall, Cambridge, to the Hon. Mary Agnes Windsor Clive, youngest sister of Lord Windsor.  
**TRENTELS—LEMMENS.**—On July 18th, at l'Église Évangélique, Rue du Musée, Brussels, by M. le Pasteur Rochedeux, Jules, eldest son of the late Guillaume Trentels, of Rue de la Pépinière, Brussels, to Ida Anne Caroline Florence, youngest daughter of the late Charles Daniel Lemmens, of Brussels.

### DEATHS.

**BURTON.**—On July 9th, at Crumlin, co. Antrim, Dr. Bindon John Burton, aged 73.  
**CLARKE.**—On July 19th, at The Thorns, Sevenoaks, Frederick Le Gros Clark, F.R.S., F.R.C.S., in his 82nd year.  
**GEORGE.**—On July 10th, at Colney-hatch, William Heming George, L.R.C.P. Edin., L.F.F.S. Glas., Senior Assistant Medical Officer of the London County Asylum, aged 40.  
**GRAY.**—On July 13th, at Brigg, Lincolnshire, Charles Edward Gray, M.D., late Surgeon Royal Navy, and Physician, Melbourne Hospital, aged 44.

**HUSBAND.**—On July 18th, at The Roost, Clifton, Bristol, William Dalla Husband, F.R.C.S., D.L., J.P. (late of York).  
**TYLDEN.**—On July 10th, at Harewood-square, N.W., Henry John Tylden, M.D. Oxon., aged 35.  
**WEISS.**—On July 4th, suddenly, while yachting at Gosport, Hubert Foveaux Weiss, F.R.C.S. Eng., L.R.C.P., L.M.R.C.P. Irel., F.R.G.S., F.R.M.C.S., M.W.L.M.C.S., late Assistant Surgeon at the West London Hospital, of 6, Granville-gardens, Ramsgate, and 27, Piccadilly, W., aged 37. Friends kindly accept this intimation.

Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

"HORRORS OF THE HIGHWAY."

UNDER this title we commented lately on the tremendous burden and strain imposed upon the horses engaged in the London omnibus service, particularly when, in addition to the excessive weight of the vehicle and its inmates, the frequent stoppages and "spurts" occasioned by passengers getting in or out or up and down, as the case may be, multiply the exertion of the poor animals tenfold. A Berlin correspondent, *à propos* of this latter feature of the service, suggests that "London should follow the example of Berlin in having halting-places at short distances apart. Of course," he adds, "it is somewhat trying to see the trams coolly pass one, and very great was my astonishment when I first came to find that the raising of my finger had no effect, except to elicit an amused smile from the conductor. Passengers are none the worse for this arrangement; on the contrary, they are much the better, when time is precious to them; and most certainly the horses must benefit by it." There is much to be said for this method of economising the horses' powers and the passengers' time, and its adoption from Berlin would be one of the least objectionable importations from that semi-military and rather rigidly organised capital.

**G. Clarendon Hamilton, M.B.**—In the case of perfect strangers it is reasonable that the medical man who acts on the emergency for his absent brother, should be promptly thanked and offered the half-fee; and this is a common rule. We can easily imagine such a fee being declined, but it is only reasonable on the part of the gentleman who has been so served to offer it.

**J. Warrington.**—We can only refer our correspondent to our advertising columns.

**St. Bernard.**—We do not recommend practitioners.

OPHTHALMOSCOPY WITH ELECTRICITY.

To the Editors of THE LANCET.

SIRS,—Some few years ago at the Ophthalmological Society I remember seeing an ophthalmoscope shown by Mr. Juler, which had a small electric lamp attached to the mirror. I should be glad if any of your readers could inform me whether any London makers supply such an instrument, and at what price.

I am, Sirs, yours faithfully,

PHILIP JAMES, F.R.C.S.

Wellington, New Zealand, June 10th, 1892.

## MEDICAL ADVERTISING.

THE following advertisement is from the *Walthamstow and Leyton Guardian* of July 9th. It is to be deprecated that a medical practitioner cannot cease connexion with a given address without advertising the fact in large type in a local paper:—

"Professional Notice!—Dr. Steven begs to intimate to the inhabitants of Walthamstow that he has severed all connexion with 4, High-street, and that in future his permanent address will be 41, Blackhorse-road."

The following has a distinctly trade advertisement character. It is from the *Manchester Evening News*:—

"Notice of Removal.—Dr. Courrie's consulting rooms for diseases of women and children removed to 199, Chester-road, Hulme, Manchester. Hours, 11 to 3 and 6 to 8."

*Mr. T. W. Story.*—We regret that it is manifestly beyond our province to be able to give our correspondent the information he requires.

## FRACTURE OF THE NECK OF THE FEMUR.

To the Editors of THE LANCET.

SIRS,—About five years ago you most kindly inserted for me in THE LANCET one or two letters about an old lady, a centenarian, named Sarah Markham, of Roxby, Lincolnshire. At the time the letters excited a good deal of interest in her and brought her many friends. In early life Mrs. Markham was in the service of Tom Sheridan and helped to bring up his three daughters, who afterwards became most distinguished ladies, one of whom was the mother of the present Marquis of Dufferin. I now regret to say that recently Mrs. Markham died, not exactly from old age, but from the effects of a fall which she had on the eve of her birthday. The accident occurred through her throwing a basin of water out of her cottage door; the act causing her to slip or overbalance herself and thus in the fall she fractured, I am told, the neck of her femur. Mrs. Markham's birthday was on Royal Oak Day and she lived a month after the occurrence, so the days of the years of the life of the old lady were 107 years and one month—a goodly age, no doubt and one to which few of us can hope to reach. Perhaps the old lady living in Scamblesby in the so-called insanitary house, who is in her one hundred and third year, may reach or exceed the patriarchal age of Mrs. Markham. Mrs. Markham was a most intelligent woman and her fine memory and love for reciting poetry remained with her nearly to the end.

Fracture of the femur is a frequent cause of death in old people. I knew an active and healthy old gentleman ninety-six years of age who whilst in the act of jumping from the top of a five-barred gate in a field on his land, was blown down by a gust of wind and had his thigh bone broken, the injury causing his death. Several cases of a similar kind have come under my observation.

I am, Sirs, yours faithfully,

Lincoln, July 19th, 1892.

WILLIAM O'NEILL, M.D.

## AIR PASSING AUDIBLY BY THE VAGINA.

*DR. SOCHAVA* reports in a Russian medical journal the case of a patient who for some years had been annoyed by the audible passing of wind from the vagina whenever she lay down or reclined in an easy chair. On examination he found a defective development of the labia and nymphæ, which were rather rigid, and prolapsus of the anterior vaginal wall, so that the vagina was directly accessible to the entrance of atmospheric air. Every contraction of the vaginal walls of course expelled the air and so caused a certain amount of noise. Energetic treatment of the prolapsus led to a cure of this exceedingly troublesome condition.

*DR. Q. C. Smith (Austin, Texas).*—No works on this general subject have been recently published. Our correspondent would find the books of Sir Joseph Fayrer and Dr. Ronald Martin useful.

## THE ACTION OF HYDROCHLORATE OF COCAINE.

To the Editors of THE LANCET.

SIRS,—I have unhappily been a sufferer from nasal polypi (mucoïd) for some years and from time to time I have them removed by the electric cautery. I have also had both lower turbinated bones chiselled out. I find that during the growth of the polypi, when of course there is considerable nasal catarrh, nothing gives me so much relief as painting the posterior nasal cavity with a 15 per cent. solution of hydrochlorate of cocaine; it contracts the polypi and the mucous membrane and arrests the thick mucus secretion, this relief lasting for perhaps two or three hours, when I usually repeat the application with a camel's hair brush. This use of the drug produces ringing in the ears and a stunned feeling such as I have felt after the near discharge of heavy artillery; and of course, if any trickles on to the soft palate or fauces, it produces retching. The question I wish to ask is whether the use of cocaine in this way is likely to be injurious to health by causing tissue degeneration or in any other manner. Of course I do not swallow any of it, and the amount I use each time is about six drops. I shall be very grateful for an opinion in your columns.

I remain, Sirs, faithfully yours,

Frocester, Gloucestershire, July 13th, 1892.

COCAINE.

## THE WARMEST PLACE ON EARTH.

THERE are several of these "claimants" for the highest temperature on the habitable globe. The Central Sahara registers a mean of 97° in July. Central Australia boasts of 94° in January—a mean which is attained in South California and Inner Arabia in midsummer. But a recent report of the New York Meteorological Bureau tells us that a Californian Valley between seventy and eighty miles to the east of the Sierra Nevadas, running in a north-north-westerly and south-south-easterly direction between two mountain ranges—the Tunal (6000 ft.) and the Amargosa (10,000 ft.)—has the highest temperature yet recorded. This valley lies below the sea-level at a depth variously estimated at from 100 ft. to 175 ft., and its reputation for excessive heat and extremely low humidity is built upon such tragic incidents as sudden death from insolation incurred by those who have ventured into it, culminating in the total extinction of an immigrant party from heat and thirst in 1850. The latter occurrence, indeed, gave it the title it goes by—"Death Valley." The report above referred to sets forth that in four months out of five during which readings were taken the mean temperature rose above 90°, in July and August exceeding 100°, while the mean for the entire period was not less than 94°. The minimum was usually above 70°, while an absolute maximum of 122° was registered on three successive days at the end of June and beginning of July. On July 18th, 1891, the New York meteorologists had the uncomfortable experience in Death Valley of spending a day in which the maximum temperature was 120°, the minimum 90°, and the mean of all hours 108° 6', while the hottest spell of all occurred from this day onward to July 24th, when the minimum never fell below 85° and the maximum ranged between 119° and 121°. The rainfall during the five months reached a total of only 1'40 inch. The winds, on the other hand, were of great force and frequency, those from the south prevailing every three or four days, while their velocity would rise from thirty miles an hour to over forty-five miles. Such gales were of but brief duration, but one of them, on June 17th, lasted from 10.40 A.M. till 6 P.M. as "one hot continuous blast," the temperature of the day being 112° 6'. These high winds assume the character of the simoon of the Sahara; the loose, friable soil contributing clouds of sand, which often conceal the surrounding mountains. What with the heat and the nature of the soil, vegetation was extremely scanty; at the bottom of the valley indeed well-nigh non-existent. Animal life was hardly to be seen; the stinging gnat by day, and the snake, the lizard and horned toad by night were its only representatives. But for one transient flock of blackbirds no winged creatures were to be seen by the New York observers, who might have given the valley the name bestowed by Virgil on a similar region from the same phenomenon—viz., "Avernus" (or Aornos, from *à not*, and *òpus* bird).

## "PSEUDO-CYESIS."

To the Editors of THE LANCET.

SIRS,—The case mentioned by Dr. Reynolds reminds me of one I had some years ago. A friend of mine, who was unfortunately suffering from an attack of typhlitis at the time, asked me to attend a confinement for him, as the friends had just sent a message to say the patient was in labour. On my arrival I found the patient sitting on the edge of the bed dressed in a petticoat and nightdress, and was informed that "niggling pains" had been coming on with regularity for some little time. Requesting the patient to get into bed, I "tried a pain," and what was my surprise on finding the cervix firm and the os quite small, while my hand on the abdomen felt no tumour in front. The general swelling was resonant on percussion and quite soft. The delight and surprise of the patient and her mother were great on my announcing the fact that it was a false alarm, as the patient was unmarried.

The striking point of similarity between this case and Dr. Reynolds' is the fact of both patients being unmarried women, and that having exposed themselves to the risk of impregnation the dread of becoming pregnant had produced symptoms of the result they both feared. In my case the mother had engaged my friend at the fourth month, and the patient herself had remained in-doors since the cessation of the menses a month after connexion.

I am, Sirs, yours faithfully,

Southfields, S.W., July 18th, 1892.

CECIL ROBERTSON, M.B., C.M.

## THE ETHICAL ASPECT OF AGREEMENTS TO SERVE ON MEDICAL AID SOCIETIES.

A CORRESPONDENT invites us to comment on the ethical side of such agreements. We may take an opportunity of doing so when occasion arises. Meantime each man who accepts such appointments ought to consider for himself the ethical as well as the legal aspects of his action. He may easily imagine that the whole profession of a town would not discountenance the holders of such appointments if there were not something questionable in accepting them. Are we to understand that in his Question as much as a guinea is charged for attending a whole family per year? May we ask if there is a wage-limit, and what proportion of the families pay this sum?

## FUNERAL REFORM.

THE Registrar-General has written the following letter to the Secretary of the Funeral Reform Association:—

"Although prompt registration is very desirable, long journeys to the registrar in order to effect it prior to interment may be dispensed with. By transmission of a medical certificate of cause of death to the registrar through the post, accompanied by a stamped envelope for reply, the friends of a deceased person may obtain from that officer by return of post a certificate of notification of death, which for burial purposes is of like value with his certificate of registration. The death can then be registered on the first visit of the registrar to the neighbourhood in which the death took place. The Registrar-General is of opinion that anything in the nature of provisional death registration could only have the effect of adding to the trouble of informants, since, unless the registration practice of the last half-century were reversed, it would always be necessary that their signatures should be attached to the entries made by the registrar."

## "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—Your correspondent "Verax" may have had very unfavourable treatment during his career as assistant and may feel even a relief in his present position, but I fear the shoe will pinch him some time. His scarcely veiled threat of the action of the friendly societies (not very friendly to the medical profession) through the House of Commons might be treated with the contempt it deserves if it were not for the miserable want of cohesion in our profession. A strong trade union is the most drastic and perhaps effectual remedy, but one to which only despair will drive us. Surely, even "Verax" would join such a union if he saw that it is only the *abuse* of his friendly society institution we complain of. Your correspondent does not appear to consider in his calculation that £300 would not pay the working expenses of many practices, nor does he state that his clients pay him a penny per week per head; the usual payment in such institutions is much lower. The fact of the matter is this. The profession is being degraded by low contracts with people able to pay moderate fees, and such men as "Verax" are assisting to degrade the profession and pauperise the people. They are not the only sinners, but their position being a public one they are more prominent. The secondary impression upon the mind of the public that medical services are worth little or nothing is a most serious one; and when we have all had enough of it, as I have already, we may hope that reform will begin. Meanwhile we must "possess our souls in patience."

I am, Sirs, your obedient servant,  
Loughborough, July 16th, 1892. J. B. PIKE.

## THE OUT-PATIENT DEPARTMENT.

To the Editors of THE LANCET.

SIRS,—The thanks of all London practitioners, especially of those living in the neighbourhood of the great hospitals, is due to you for your article on the out-patient system in your last issue. The usual excuse alleged by the hospital authorities for the existing state of things is that these out-patients are necessary for the training of the students; but of what use is it to train them for the practice of their profession unless there is something for them to do when they are trained? We are at the season of the year when parents and guardians are making their arrangements for entering their sons and wards as medical students. Let them fully consider what they are doing before they spend their money in preparing them for a profession in which there is so little chance of earning a decent living. Why do we not hear more of the "hardships" of the general practitioner's life? Because to make them known is to proclaim himself to be one of "those whom it is not generally desirable to protect."

I am, Sirs, yours faithfully,  
July 10th, 1892. A GENERAL PRACTITIONER.

## MEDICAL ASSOCIATIONS AND MEDICAL LEGISLATORS.

THE Mississippi Valley Medical Association boasts one great advantage over similar bodies—"that nothing can be discussed during the session save and except science." All ethical matters are referred to committees whose decisions are final. "Precious time is not allowed the demagogue or the medical legislator." Does the Mississippi Association mean to imply that "demagogues and medical legislators" are allowed too much rope in other scientific medical bodies? The charge is a curious one, which we leave other associations to answer.

## A COASTING TRIP.

To the Editors of THE LANCET.

SIRS,—I am anxious to get as much sea air as possible during a short holiday, and see that steamers are advertised to sail from Liverpool round the north of Scotland to Leith. Can any of your readers tell me whether there is suitable accommodation for a lady on such steamers? I do not, of course, mean Atlantic liner style, but such as would make the trip endurable if the weather was bad enough at times to make it necessary to be a good deal down below.

I am, Sirs, yours truly,  
July 10th, 1892. A. E.

## MINERS' STRIKES AND THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—May I be allowed to ask your opinion on a certain matter which affects not only myself, but nearly all the practitioners in colliery districts in this county?

First, I would state that we practitioners receive our money (that which comes from the miners) on a kind of club system, every miner paying 6d. per fortnight, which covers attendance on himself and family for the ensuing fourteen days. As a rule this is collected by the overmen at the various pits, the 6d. being stopped out of each man's pay, for which service we have to pay the overman 10 per cent. or 7½ per cent. of the gross amount. In consequence of the recent strike in the county the miners' subscriptions were never deducted during ten of the twelve weeks. During the first fortnight of the strike, however (at this colliery at any rate), 6d. per man was kept off the week's money that the owners keep in hand. The amount to which we are entitled therefore is 2s. 6d. per man. We have been working the whole time in the same way as if the subscription had been going on as usual, fully expecting that the men would fulfil their part of the contract, which they as a body refuse to do, although many of them individually are honest enough to pay. The question I wish to ask is, can we legally claim the 2s. 6d. back money? If so, it will be a great boon to many practitioners beside myself; for when one has, say, 500 subscribers and perhaps fifty of them pay their just debts it means a clear loss of £50 10s., besides the fact that working expenses (drug bills, assistants' salaries, horse and trap, &c.) have been going on all the time.

I shall be greatly obliged if you will give me your opinion on the matter and I will communicate with the neighbouring practitioners.

I am, Sirs, yours faithfully,

R. E. INGRAM-JOHNSON.

Chester-le-Street, Durham, July 10th, 1892.

\*.\* We think the recovery of the money might be very difficult. We presume our correspondent would have to prove a specific contract with each individual miner, and must take proceedings against each and not against any aggregate body. Our correspondent has our hearty sympathy.—ED. L.

## SALE OF PRACTICES.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me how the measurement of the distance is determined in the case of selling a London practice? Is it according to the nearest cab route, or as the crow flies? What is the customary limit in the sale of a West-end practice, and for how many years is it reasonable to prohibit practice in the locality?

I am, Sirs, yours faithfully,  
July 17th, 1892. LEONARD.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Althaus, London; Dr. Aitchison, Wallsend-on-Tyne; Messrs. Anderson and Co., Edinburgh; Mr. F. P. Atkinson, Surbiton; Mr. W. Adamson, Liverpool; Mr. Arrowsmith, Bristol; Mr. Blacket, London; Mr. James Braithwaite, Leeds; Messrs. Battle and Co., Paris; Mr. Stanley Boyd; Mr. Bobardt, Newbury; Mr. Baron, Manchester; Messrs. # Medical Diary for the ensuing Week.

Monday, July 25.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30 P.M.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

Tuesday, July 26.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.

Wednesday, July 27.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Ophthalmic Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, July 28.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, July 29.

ROYAL SHERFORD LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, July 30.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

## SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 16 3

TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES

ABROAD ..... One Year 1 14 8

\* \* \* In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 8d., instead of £1 16s. 10d. as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

## ADVERTISING.

The Publisher cannot hold himself responsible for the return of testimonials &c. sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement. Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET. Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

Address in Medicine,

Delivered at the Meeting of the British Medical Association at Nottingham,

By JAMES CUMING, M.A., M.D., F.K.Q.C.P.I.,  
PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE,  
QUEEN'S COLLEGE, BELFAST.

IN his opening remarks Dr. CUMING referred to the fact that, although the profession of medicine had lost somewhat of its repute in respect to learning, yet at no time had there been more assiduous cultivation of medicine, or its claims to public usefulness been capable of being so triumphantly indicated. He thought that its progress might be furthered still more if chemistry, botany, and natural philosophy were to a great extent banished from the curriculum, since, whatever their value, as developing habits of careful and accurate observation, it could not be denied that there are several subjects more closely identified with medical science which afford ample scope for wide and exact mental discipline. He asked whether as at one time it was necessary to defend medicine from the overweening pretensions of authority and prescription it may not now be necessary to shield it from the excessive demands of science, and he then proceeded as follows:]

We may now leave the negative part of our subject and turn to what constitutes the indispensable parts of our equipment. Besides the so-called practical subjects—medicine, surgery and obstetrics—we should know all that can be learned about the structure and the functions of the human body. Our anatomy must be thorough, although it is instructive to remember, even in respect of a subject so absolutely essential as a groundwork of medicine and surgery, that a surgeon of no less eminence than Lawson Tait entered his protest in Birmingham against the unnecessary minuteness and elaboration of even anatomical teaching. For my own part I am inclined rather to adopt the standard of Huxley, that anatomy should be so learned that the body will be as it were transparent to the eye.

Now one cannot fail to be struck with the fact that among the subjects of greatest present interest there are two which seem to give evidence of distinct currents of thought moving apparently in opposite directions. On the one hand, we find an important part in pathological and physiological processes ascribed to minute organisms, the white corpuscles or leucocytes, which are apparently free from all direct nervous influence and float freely in the blood; and, on the other hand, we find that the domain of the most highly-organised and differentiated part of the body, the nervous system, is being extended and increased. It seems as if attention was being divided not unequally between the simplest elements of the body and the most complex portion of its structure; shared between little masses of protoplasm, which present but slight differentiation in structure, and the nervous system with all its complicated and refined activities and powers. And even, what is still more remarkable, we find a certain similarity in function suggested as existing between these seemingly widely different portions of the economy. It has been long known that unicellular organisms, amoeboid cells, possess the power of choosing their appropriate nutriment and of rejecting what is harmful or useless to them. These facts have been for a considerable time familiar to naturalists and their remarkable character has caused them to be studied with much interest. It has been abundantly shown in respect of animals higher in the scale, but possessing either no cerebral hemispheres or only a rudiment of them, that they are capable of much and varied bodily activity in response to suitable stimuli. With regard to the human body, it has been also established that osmosis does not take so important a part in nutrition as was formerly supposed and that a distinct selective power is exercised by the epithelial cells of the intestines, which, for example, pick out the globules of fat from the materials within their reach and transmit them to the commencement of the chyle vessels. Now the striking observations of Metschnikoff regarding the action of the leucocytes on microbes, the phenomena of phagocytosis, have naturally been received with more favour owing to the knowledge we possessed of facts presenting some analogy with his observations.

No. 3596.

The instructive discussion which took place in the Pathological Society of London during the earlier months of the present year has brought, more prominently than formerly, the facts on this subject before the profession in this country. In the main, I think, we are compelled to accept Metschnikoff's views as representing the present state of our knowledge, and accordingly we must accept phagocytosis, notwithstanding the opposition of some observers of great weight and authority, and notwithstanding some considerable objections. It seems then to be established that certain cells, of which the leucocytes are the most important, possess the power of attacking and destroying certain infective microbes when introduced into the body; that these free, mobile and apparently quite independent organisms act in a manner highly important to the integrity and safety of the body at large, protecting it under suitable circumstances from the injurious effects of virulent bacteria. So much I think may be regarded as fairly established, even should Buchner's views regarding the importance of antibiotic fluids in the blood be ultimately established. It is, however, with a certain degree of wonder, not unmingled with distrust, that we find something of the purposive character which has hitherto been supposed to be the exclusive endowment of conscious beings attributed to these minute, hardly differentiated masses of protoplasm. We learn that under the influence of chloral the leucocytes refuse their work and become anaesthetised, so that the bacteria have it all their own way. We are told that they show a liking for some substances and an instinctive aversion for others, and some facts are adduced regarding their mode of warfare which seems to point to a more than nascent civilisation. One observer describes them as marching right up to the bacilli and attacking them, which seems analogous to the Napoleonic tactics in battle, while the lymphocytes are described as forming a second line of defence, a method suggestive of the more watchful strategy of Moltke. Altogether the demeanour and endowments of the cells open up a field for investigation both as regards cell action in itself and as regards its relation to the organism generally which contains much that is of the highest pathological and physiological interest. A new cellular pathology is being developed, differing widely indeed from the brilliant theory bearing this name so long familiar to us from the powerful advocacy of Virchow, but agreeing with it in the important functions assigned to the ultimate elements of the body as independent factors both in morbid and in healthy processes, and also in representing them as being either uninfluenced or as only indirectly influenced by the nervous and vascular systems in some of their essential activities.

Now while phagocytosis is directing our attention with increasing interest to the minutest and most elementary constituents of the organism, on the other hand renewed zeal is being shown in investigating the complex problems which the nervous system presents to the inquirer. Even with regard to those more doubtful subjects which are in the borderland of legitimate scientific inquiry a revival of interest has taken place. Hypnotism and its allied states have long exercised a powerful fascination on a large portion of the intelligent public, and have been looked on with much curiosity, but always with a little suspicion by physicians. Although not new these singular and striking manifestations have of late been more carefully studied, the methods of producing them have been more clearly ascertained, and one is glad to notice that, instead of being relegated to non-professional men, they have engaged the attention of some of the physicians most competent to conduct such inquiries and most capable of estimating their results with precision and judgment. Whatever verdict may ultimately be passed on hypnotism there can be no reasonable doubt that certain facts have been elicited which show that in the hypnotic condition profound and extensive modifications occur in the sensory and motor functions of the brain. Now admitting much that has been urged against hypnotism; granting that it is likely to attract the attention of men who have a liking for the marvellous; that it can be practised by men possessed of no scientific training and incompetent to deal with the most refined activities of the nervous system, and that it thus lends itself easily to charlatanism and imposture; granting that it may be attended with danger of a formidable kind and also that its field of therapeutic usefulness is likely to be at best a very restricted one, and its effects probably only transitory; still it is a subject eminently deserving of careful and profound scientific investigation, conducted under the most rigid precautions, so as to exclude intentional or involuntary deception. We do not need to be much

concerned about whether, as has been stated, we have in hypnotism a condition akin to natural sleep, or whether it is in reality a pathological state related to hysteria. What is at present wanted is a clear account of the phenomena which are capable of being produced under its influence. If, as numerous statements aver, hypnotic suggestion can be shown to in any degree affect processes of nutrition and the reaction to irritants, then some points of the very highest interest as regards the influence of psychical on physical processes will have been established. Most of us have been inclined to read with a considerable degree of scepticism the accounts of instances in which obvious physical changes have been stated to have resulted from nervous influence, especially when these changes have occurred in a rapid manner. Should the statements on this subject which have been made so positively and on the faith of apparently cautious and trustworthy observers prove to be authentic we shall certainly be compelled to reconsider our position with reference to them.

The opinion is very generally entertained that the diseases of the nervous system are now more widely diffused and more numerous than formerly. It is somewhat difficult to obtain accurate statistics on this question and not altogether easy to ascertain their precise value, but some facts seem open to no serious question. In Ireland the proportion of the insane to the population has steadily increased. I owe to the kindness of the Registrar-General for Ireland the numbers of those mentally affected as shown in the Census of 1891 as compared with that of 1881. The numbers of the insane including idiots were in 1881, 18,313; in 1891, 21,188; an increase of 2875, although the population has diminished by 453,677. The proportion is 224 to each 100,000 of the population. Even allowing for the fact that emigration takes away in the main the healthy and strong, and that consequently this represents the proportion of insane to a much larger population than now exists in the country, still it indicates a very notable increase. The reports of the Registrar-General for England show an almost uninterrupted increase in the mortality from nervous diseases. Some of this is no doubt explicable in other ways, but on the whole the evidence of statistics coincides with the general opinion among physicians that there is an augmentation. Whether this depends on the increase of causes tending to overwork and weary and exhaust the brain and nervous system we need not at present stop to discuss. Now, even those of us who have no special connexion with the treatment of the insane find ourselves frequently brought into contact with questions regarding insanity. Apart from the mere granting of certificates, which, however, is attended with much anxiety and with heavy legal responsibility, there are the numerous minor forms of aberration in which it hardly becomes a practical question whether they necessitate restraint or not, and there are also the many instances in which general affections produce mental phenomena. Then we have the numerous cases of temporary insanity which are never known beyond the families of the sufferers and the medical men to whom their care is entrusted, as well as the incipient stages of mental disease in which skilful management is of the utmost importance. It was no doubt in consequence of considerations based on these facts that systematic instruction on the subject of mental disease has been adopted by some of the examining bodies as a necessary part of the training of the practitioner in medicine, and has thus become a recognised portion of medical education. I may add that the existence of the Psychological Section of this Association is a further proof of the importance of this branch of inquiry to the medical practitioner.

Now, the study of medical psychology alone is to my mind a very incomplete and inadequate preparation for comprehending the multiform disturbances of mental function and is even more inadequate in respect of either diagnosis or therapeutics and in regard to the expectation of adding to our knowledge of cerebral diseases as regards either localisation or character. I have long been of opinion that some knowledge of psychology proper—that is, of the science of the phenomena of mind in its normal conditions—is absolutely necessary. Without an acquaintance with the problems and methods of psychological inquiry it is impossible to observe and to describe adequately the phenomena of morbid mental states. In the investigation also of those conditions in which the disturbance of a single function is what is most manifest and striking, it is clear that a knowledge of the limits of differentiation of function must be of capital importance. It will be of value also to become familiar with the terms used in psychology, in itself a study of no inconsiderable difficulty and extent. In dealing with such questions as amnesia, aphasia, delusions

and hallucinations, and other disturbances of consciousness, we are not only in the sphere of our legitimate activity and of our daily work, but we are touching, not indirectly, on some of the most interesting problems of mind. In examining these questions we get into one of the main currents of modern thought, and have suggested to us some problems which have engaged the attention of many of the acutest intellects of ancient and modern times. Some psychologists refuse to accept any help from physiology, and fortify themselves in the citadel of introspection, declining all external aid. It is said by them that the comprehension of physical processes throws no light on psychical processes, and that these are absolutely heterogeneous. I am not concerned to defend the claims of physiology, which find advocates enough, but in respect of morbid conditions, when we find misery and despondency connected with defective digestion, perversions of the will and deceit attending on hysteria, emotional instability, causeless anger and childish tears and laughter accompanying the later stages of chronic damage to the brain; when, to take a simpler and more-transitory influence, we find alcohol leading to the well-known mental exhilaration which attends the early stages of its effect; when we find opium, in those accustomed to its use, producing such agreeable sensations that De Quincey could state: "Here was the secret of happiness, about which philosophers had disputed for so many ages, at once discovered; happiness might now be bought for a penny and carried in the waistcoat pocket; portable ecstasies might be had corked up in a pint bottle; and peace of mind could be sent down by the mail"; when we find all these and many kindred mental accompaniments of physical changes brought to our knowledge we have the strongest motive to attempt the analysis of the material lesion and of its modifications and varieties. Some of our greatest observers attach much moment to the entire and absolute denial of any relation of cause and effect in these events, and they insist on regarding the neural occurrence as merely concomitant with the mental occurrence. Now, we may grant at once that the nexus between them is as yet undiscovered and may be undiscoverable; but in investigating mental phenomena from the physical side we are doing something that can hardly fail to throw light on certain obscure questions, and we need not embarrass ourselves with any considerations regarding the real connexion or relation with each other of these concomitances. For my own part, I may be permitted to say that the progress of psychology is, I think, in a great measure to be sought for at the hands of the members of the medical profession. In physiology I am convinced that pathological and clinical observation have done more than experiment to elucidate function; and in like manner I have little doubt that the study of morbid and limited and incomplete mental and cerebral manifestations will throw a great deal of light on some of the most abstruse questions in the relations of matter to mind. It will be bringing into action the logical method of difference, the ascertaining the influence of the removal of part of the cause on the effect. Now in assisting in the solution of these grave problems I think our function as medical men is in the main a limited although a highly important one. Our obvious duty is to collect such a body of facts as will afford a sure foundation for future generalisations. Besides the states of marked and more or less well-defined disease which enter of right into our nosological classifications we have a wide field in examining into the influences of habit and heredity, the cerebral peculiarities which, more or less transformed, descend from generation to generation, constituting an "innate preparedness" for the development of particular morbid phenomena; the relations between vice and disease; and the question of when criminality implies merely pathological conditions.

I think we should avoid, at least for the present, the more ambitious philosophical attempts which have exercised during many generations a powerful influence on some of the highest intellects of our race. We need not attempt the great metaphysical questions of substance, reality, the nature of consciousness, the ontological nature of space and time, the essence of causal action and the like. The domain of the clinical and pathological observer is a humbler, but, we may fairly congratulate ourselves, a more fruitful one. Just as biology concerns itself with the manifestations of life and puts aside all theories regarding its nature and origin; just as, in fact, all sciences have to resolutely set aside at the beginning a certain number of unsolved questions, so we may fairly relegate these problems to other and more competent

authority. Nor do I think we should gain much at present by attempting to form any wide generalisations. A working hypothesis is no doubt of the highest utility in an experimental science, even if it ultimately comes to need to be corrected or to be altogether abandoned; and, if the facts which come before us were capable of being called into existence or of being modified at pleasure, such a hypothesis might be necessary for our guidance. But we have to deal only with phenomena not susceptible of voluntary modification, and what we have to do is simply to observe them with accuracy and to record them with fidelity. In these observations the materialist, who regards mind as a form of motion in the brain-cells, and the spiritualist, who looks on it as an immaterial principle underlying the phenomena of consciousness although acting through the nervous system, can work together in perfect harmony, as the problem is to observe and analyse the phenomena brought before them. Even in this task there are limits set to our observations which it is not easy to surmount or evade. Physiologically it seems improbable that we shall ever be able to identify or to accurately estimate the results of mental activity in the shape of oxidation products of brain substance. The weight of the brain is about 2 per cent. of that of the body and we can hardly doubt that in mental processes only a small portion of the cerebrum is employed at any given time. Besides, we have no measure of the relative degrees of intellectual exertion and consequently cannot express them in terms of potential energy.

The nerve-cell must doubtless be accepted as the ultimate unit of the nervous mechanism and the nerve-fibre plexus as containing or constituting the channels of communication between these elementary units of cerebral activity. When we come to localisation of function, with the exception of the motor areas and Broca's convolution and some further fairly definite areas concerned in disturbances of language, we have little which is well ascertained. If, as is hoped, we can make out that in the brains of the insane special areas are differently and disproportionately affected, it is not unreasonable to suppose that these areas may ultimately be ascertained to be connected with special functions. Charlton Bastian long ago expressed the opinion that the posterior lobes of the cerebrum are the most important for intellectual purposes and this view has received the high sanction of Hughlings Jackson. On the other hand, Bevan Lewis<sup>1</sup> lays down without hesitation the following principle regarding insanity. He states that while acute insanity may be regarded as a very general implication of the sphere of mind, and hence of a widespread disturbance of the cerebral cortex, its morbid results on the brain are decidedly concentrated on the motor or fronto-parietal section of the hemispheres. We learn from these conflicting opinions how little is definitely ascertained regarding the most important developments of cerebral activity. If I might indicate some definite lines on which medical observation might be of the greatest value in elucidating some unsettled problems I should be inclined to name among others the aberrations and decay of memory. For this species of observation no apparatus is necessary and the opportunities are daily offering themselves and most abundantly to the busiest practitioner. Have we as yet any sufficient number of facts to justify the dissolution view of the decay of memory—that is, that in the decay of memory there is a certain definite sequence of events. The law of regression, as it has been formulated by Ribot, corresponds to the general principles of dissolution as a reversal of evolution which have been enunciated by Hughlings Jackson with his usual force and ability. The process of decay would then go on in a regular gradation, from the complex to the simple, from that which has been least thoroughly organised or incorporated into the brain to that which has been most so, from the least to the most automatic of our acquisitions, so that we first forget recent events, then intellectual acquirements, then the impressions which belong to the domain of the feelings, and, finally, how to perform automatic acts. All this, of course, depends on a supposition that a physical modification of some of the very many millions of cells of the cortex of the brain takes place originally in connexion with the mental process which memory revives, this modification constituting the organic basis or anatomical substratum of memory. It is suggested that it is in this way that we can best comprehend the retention of impressions which are for a time absent from consciousness, just as it is the intercommunication of the cells which enables us to conceive

how the impressions can be revived. But is this law fairly established? When we reflect on the enormous number of instances in which memory suffers notable, and, so to speak pathological decay in age, it would seem easy to collect and classify such a number of facts as would put this doctrine on a secure footing. But I think this is far from being the case, and the number of exceptions seems to be so great that we may fairly regard this law as at present in this important sphere, unestablished. I have recently had the opportunity of witnessing a curious disturbance of memory in a young medical man, in whom multiple neuritis had arisen in consequence of much and premature exposure to cold after an attack of influenza. Besides the usual paralytic symptoms his memory became greatly impaired. He gradually reached the point of forgetting the year and the month, became hazy about his personal identity, and was doubtful who his wife was, and where he himself was residing. *Nec domus nec placens uxor* was retained in his memory, but he still had a very fair recollection of the leading diagnostic and therapeutic facts about his profession. He had forgotten a great deal, but the platysma myoides was fresh in his recollection, and the differential diagnosis of fluid in the pleura from consolidated lung was retained firmly. These facts, I cannot but think to the no small credit of his teachers, were so organised in his brain that they resisted dissolution.

The phenomena of aphasia, which have been so much studied and about which so many curious facts have been ascertained, bring us in contact with a most interesting problem, the relations of thought to language. It is, I think, doubtful whether without words any continuous reasoning can be carried on, and it is pretty certain that in the absence of the symbol no abstract reasoning could take place. According to the fine illustration of Sir William Hamilton, all considerable progress in thought must be accompanied by a corresponding development in language. "You have all heard of the process of tunnelling through a sandbank. In this operation it is impossible to succeed unless every foot—nay, almost every inch—in our progress be secured by an arch of masonry before we attempt the excavation of another. Now, language is to the mind precisely what the arch is to the tunnel. The power of thinking and the power of excavation are not dependent on the words in the one case or the mason work in the other; but without these subsidiaries neither process could be carried on beyond its rudimentary commencement. Though, therefore, we allow that every movement forward in language must be determined by an antecedent movement forward in thought, still, unless thought be accompanied at each point of its evolution by a corresponding evolution of language its further development is arrested." Now, when we find that a special damage in one situation makes us lose the power of reviving the recollection of the word, although we recognise it when heard; that damage in another region so affects us that the sight of the word does not call up its mental representation, although we see the word plainly; and that lesions in a third region have as their result that the sound of a word will not call up the corresponding idea, although we hear the sound of the word distinctly; it is impossible not to recognise that here we have got a good way in making out the very mechanism of this potent instrument of thought, and it is difficult to see in what other way we could have arrived at a similar comprehension of these complex and refined activities. We learn from facts like these how great a part the observation of the dislocations and derangements of important functions can play in enabling us to better understand the scope and nature of the function itself. Few things are more noticeable in connexion with this subject than the amount of research which is being conducted on the subject of experimental psychology. In this direction much of the best work has been done in the Leipzig psychological laboratory by and under the direction of Wundt, but kindred investigations are being made by various observers. The researches on the intensity and the time relations of sensation and of motor response to stimuli are of the highest interest. They have enabled us to ascertain the time occupied by mental acts, by the reproduction of impressions, by acts of association and by logical judgments. The amount and quality of work done in this direction justify the hope that psychology as a natural science will take its place beside physiology, and that the physical basis of mental activity will be more and more understood and elucidated. I have dwelt, at perhaps undue length, on this aspect of my subject, partly because it has a direct bearing on the relation of medical science to other branches of

<sup>1</sup> A Text-book of Mental Diseases, p. 480.

knowledge and partly because it furnishes a convincing proof of the claim of medicine to take a leading part in the elucidation of important psychological problems.

Again, to take an instance of how medical experience can correct psychological speculation, we may, even if it be a little ungracious, select an example from the writings of a great thinker to whom many of us are under deep intellectual obligation—Herbert Spencer. This eminent psychologist<sup>2</sup> attributes an importance to the circulation in the brain which physicians would be inclined to regard as excessive. He states that quickening of the circulation in the brain causes a rush of unusually vivid ideas and makes the memory more distinct than usual. He contrasts the illusions of delirium as exemplifying the extreme vividness with which revived feelings may rise when the cerebral circulation is excessive, and the loss of consciousness caused by cerebral anæmia as exemplifying the converse result. Now we have ample opportunity of knowing that anæmia is a fertile source of delirium, as the term "inanition delirium" indicates, and while there is much that is doubtful in that most obscure chapter of pathology which deals with hyperæmia of the brain, we know that it is at least as likely to produce somnolence and coma as it is to produce illusions. If the rapidity of the blood-current were so potent as Spencer supposes physical exercise ought to heighten the receptivity of impressions and there would be even a perceptible increase in the erect as compared with the recumbent position. As a matter of ordinary observation it is found to be difficult to collect our thoughts when the circulation is much accelerated by rapid exercise and hardly possible to carry on a train of reasoning requiring any considerable effort of memory. It has been urged by Schroeder van der Kolk<sup>3</sup> that a free communication exists between the arteries and veins in the pia mater so as to allow a considerable portion of the blood, when the circulation has been quickened, to pass away over the cortical substance without entering its tissue at all, thus avoiding the disturbance which its rapid passage through the capillaries of the brain would cause. In this way, as he has put it, the storm sweeps over the brain without our perceiving it.

I have alluded to this comparatively trivial point to indicate how medical knowledge comes to have a direct bearing on subjects of wider and more general interest and to show also how physicians, by bringing their special knowledge to bear in this way on the solutions of some of the most interesting problems which can engage the human intelligence, can best vindicate the dignity of their profession, which will thus have the fairest prospect of again forming an important factor in promoting the intellectual progress of the race. Nor even in a therapeutic sense will studies of this kind fail to bear fruit in enabling us to deal more rationally and more successfully with the morbid conditions of this important portion of the economy. It can hardly be denied that there is a tendency among the most enlightened members of the profession to attach a less overwhelming importance to the administration of medicinal agents and to have recourse to the employment, instead of them, of what may be called physiological remedies for the treatment of the morbid conditions of the mind and brain. Light, air, nutriment, environment, the warding off of hurtful and the presentation of soothing impressions—these are more frequently and more successfully employed than the large class of nervines, of the remedial actions of which we are not so certain as we could wish. And when we add to these the so-called moral treatment, comprising amusement, occupation and the like, we have enumerated most of the agents on which we rely with the greatest and the most assured confidence. I do not wish to be understood as underrating the numerous and potent additions which have been made of late to our stock of nerve remedies. I like to know that they are being constantly added to and that their actions are being more fully investigated and defined. I regard them in the light of a great arsenal of warlike weapons of the newest construction and the most perfect adaptation to their purpose, kept always ready for use and in a thoroughly efficient state of order and readiness. But as I regard it as the highest and most successful statesmanship not to be obliged to employ these powerful weapons in actual warfare, so we best vindicate the efficiency of our art by having recourse to our armaments only as sparingly as may be, confident, however, that at

critical moments and in periods of active disturbance they can be employed with great and admirable effect.

It is a common and easy practice for writers to exercise their wit at the expense of the profession of medicine. Molière and Le Sage have condemned to immortality what was perhaps not a very gross caricature of some forms of practice in their day; but graver and weightier thinkers have lectured us on our shortcomings and have given us much well-meant advice. Now, there is nothing which gives us a higher idea of the ability of the earlier physicians than when we examine the opinions and theories which have been advanced by some of the most commanding intellects of the world in reference to medical subjects, and which are often ludicrous and absurd. The father of modern experimental philosophy, Bacon, brought a charge against physicians that they prescribed in too simple a manner and did not combine together a sufficient number and variety of drugs. It is but justice to say that a number of both ancient and modern therapeutists have applied themselves with no inconsiderable energy to relieve their profession from this reproach. The same great philosopher advised the employment of a peculiar bath to obviate the hardening effects of age, and he hoped by this means to promote longevity and to restore to the rigid frame of age the suppleness and freedom of youth. The bath was to consist of fresh blood, or if that were found loathsome it might be made of milk, butter, yolks of eggs and the fatter kinds of flesh, with oysters and wine, and sweetened with sugar or honey. This extraordinary bath was to be followed by various anointments and frictions. It is hardly to be wondered, when one reads this curious prescription, that Harvey, who was said to have been his physician, remarked of him, "He writes philosophy like a Lord Chancellor." Berkeley recommended, as is well known, his wonderful tar water as not only capable of remedying bodily disease, but as having a valuable influence on the understanding, an effect of matter on mind which we would hardly have expected from the great master of idealism. "Nor is it only useful to the bodies of infants," he says, "it hath also a good effect on their minds, as those who drink it are observed to be remarkably forward and sprightly." When we remember that at the time this passage was written Cullen and William Hunter were teaching medicine and anatomy we have no reason to think that the physicians of that day had much to learn from the metaphysicians. Kant, the most profound speculative genius of Germany, was strongly opposed to vaccination, which he called "the inoculation of bestiality," and he was enthusiastic about what he regarded as the great discoveries of Beddoes regarding the prevention and cure of consumption. One of these discoveries was the use of digitalis as a remedy for phthisis, which Beddoes regarded as opening out a brilliant era for humanity, as in his hands it cured a large number of cases.

Now, when we see the notions which existed on the subject of medicine among these great and highly endowed thinkers we can form some idea of the views which would in all likelihood find favour among the masses of mankind and the effects to which such views were likely to lead, and we can form, too, a fairly adequate notion of the superiority on their own ground of the contemporary leaders of medical science. We can see, too, what important services legitimate medicine has rendered to the world, even if it had only the negative merit of protecting mankind from disastrous and ignorant meddling. Physicians cannot accept the position of mere *curiosi nature*; in presence of serious disease they must act with the best means they possess. Failing in this duty they would be justly liable to the reproach of Mephistopheles:—

"To grasp the spirit of medicine is easy,  
Learn of the great and little world your all;  
To let it go at last, so please ye,  
Just as God will."

We must always remember that it is by its utility to the world that medicine must ultimately stand or fall, but we must use the word utility in its widest signification as comprising, on the one hand, all the special activities of our profession in preventing or mitigating or removing human suffering, and on the other all its incidental advantages in aiding the development and progress of human intelligence by taking its position along with other members of the group of sciences of observation. It is to be regretted, but I fear it is inevitable, that the study of the old humanities must be curtailed and must even in some measure disappear from medical education. Greek seems doomed past recall, and it will perhaps be possible to say at some future day of the

<sup>2</sup> Principles of Psychology, vol. 1., p. 287.

<sup>3</sup> Mental Diseases, translated by Rudall. London: Churchill, 1870, p. 36.

medical profession, as Petrarch said of Italy in the fourteenth century, that it did not contain more than ten persons who could appreciate Homer. And yet, in putting aside Greek, medical men will miss some of the finest products of the human intellect moulded in the most perfect form. Many of those who take an interest in the study of the subjects I have been imperfectly advocating will be glad to be reminded of what is surely one of the most touching passages in ancient literature, that in which the scene before the death of Socrates is related in the *Phædo* of Plato, when the illustrious old psychologist after his fetters had been removed began to bend and rub his leg where the chain had galled it, saying as he rubbed: "How singular is the thing they call pleasure and how curiously related to pain, which might be thought the opposite of it; for they will never come to a man together and yet he who pursues either of them is generally compelled to take the other." Our psychologists are to-day still busily engaged in investigating the same problem.

Latin will make a harder fight to maintain its place and will probably succeed in retaining it. If it should fail it will be impossible not to feel a profound sense of compassion for the physicians of the future if they are never to be admitted to the simple feasts at the Sabine farm at which educated men have been charmed guests for so many generations, or if they are never to feel the beauty and finish of the hexameters of Virgil. I do not suggest that grace of style or elegance of diction is to be regarded as of intrinsic value in medical writings—

*Res ipsa ornari negat, contenta doceri.*

Works on a subject so changing as medicine is are destined to a comparatively brief existence and any prolonged or anxious care devoted to their form and finish would be alike unnecessary and fruitless. The classical Latinity of Mead and Heberden has not saved their works from all but total oblivion. The same fate is destined, at no remote date, to overtake the eloquent periods of Latham and the charming lectures of Sir Thomas Watson—lectures which surely not merely early prepossession which makes me regard as among the finest English prose of the generation which witnessed their publication. But good writing satisfies the literary conscience of the author and gives a not altogether undesirable pleasure to the reader. The pursuit of literature is everywhere being regarded as less necessary—and we must be of our generation—and from a utilitarian point of view it is impossible to give more than a passing regret to those branches of learning which have so long been regarded as the stamp and evidence of culture. What with unconscious irony are called the paying subjects are brought more and more prominently forward in general education and those studies which bear on professional training will ultimately prevail to the comparative exclusion of all others. But it must be also borne in mind that it is not by the mere accumulation of scientific facts that the physician of the future will gain his most valuable training. It is by those studies which develop and heighten intellectual energy and aid in forming and promoting that flexibility and grasp of mind which enable it to deal with the varying problems which medicine presents in such abundance. It was remarked by Dugald Stewart that Locke owed some portion of his success as a psychologist to his medical training. "No science could have been chosen more happily," he observes, "to prepare such a mind as that of Locke for the prosecution of those speculations which have immortalised his name; the complicated and fugitive and often equivocal phenomena of disease, requiring in the observer a far greater portion of discriminating sagacity than those of physics, properly so-called, resembling in this respect much more nearly the phenomena about which metaphysics, ethics and politics are conversant."

It will always also be of great aid to the physician to be able in dealing with those committed to his care to recognise the influence on them of ideas of hope, of confidence, of endurance; to be able to deduct from their complaints what is the result of an impressionable nervous system and what of pure imagination; to solve, as nearly as may be, the personal equation. These capabilities will supplement beneficially the most refined and accurate physical diagnosis. We need not doubt that the multiform aspects of disease, following, as they do, closely on the track of all the numerous and diversified forms of human energies and activities, will afford ample scope for the freest exercise of the highest scientific faculty as well as for the employment of the most minute and patient observation. The tendency of the

medicine of the future will no doubt be in the direction of greater specialisation. Physicians and surgeons will devote themselves more and more to the cultivation of a limited portion of the vast and always widening field of knowledge. Medicine must adapt itself to the varying necessities and requirements of the world. It must prove itself capable of supplying the wants of a civilisation rapidly becoming more complex in its development and therefore more varied as well as more exacting in its demands. It must press into its service all knowledge, physical and mental, likely to aid in the furtherance of its mission; accepting the help of its sister sciences, but allowing itself to be dominated by none of them. It must be alike flexible in its methods and steady in its aim; and it must be at once cautious and aspiring, always sane in practice, while bold in speculation. But at the same time it behoves all those concerned in its guidance, or responsible for the instruction of those who are to become its members, to bear in mind its position as one of the main supports of the tripod of learning, as one of the great factors in the intellectual progress of humanity; being well assured that it cannot sacrifice any portion of its intellectual elevation and dignity without a corresponding sacrifice of its truest and most practical usefulness.

## Address in Surgery,

*Delivered at the Meeting of the British Medical Association at Nottingham.*

By WM. H. HINGSTON, M.D., LL.D., D.C.L.,  
SURGEON-IN-CHIEF TO THE HOTEL DIEU, MONTREAL; PROFESSOR  
OF CLINICAL SURGERY IN THE LAVAL UNIVERSITY.

### SYNTHESIS IN SURGERY.

GENTLEMEN,—It has been found by some of my predecessors in this rostrum that the advances in surgery have been so great and so important that to follow them at all closely in their many ramifications would be impossible. This difficulty seems to have occurred to my immediate predecessor, the learned Edinburgh surgeon, Professor Chiene, who in his admirable address, turned at once, and for relief, as it were, to surgical rest. But the rest, aptly termed surgical, for which Mr. Chiene, following Mr. Hilton, had secured so much attention was objective. Methinks that with this much needed surgical rest there runs *pari passu* a surgical unrest which is subjective and which will be my text for a moment. On this, the eastern side of the Atlantic, where in every branch of commerce, in every trade and handicraft, in every liberal art, in every learned profession, the lines which divide the work to be done by each are, for the most part, clearly and distinctly traced, the steady agitation of life is marvellous, and would seem to favour the view long ago expressed by De Quincey that solitude was, even in his time, becoming a visionary idea in this country. Yet to me it appears life here is calm, quiet, placid when compared with that on the western continent. Here there is time for easy and familiar intercourse; there it is grudgingly given. Here you leisurely perform the functions necessary for the repair of wasted tissue and the reception of food; recreation and sleep have their due time allotted to them; there they are unduly curtailed as things which might be realised and converted into currency. This state of unrest everywhere—but especially in the western world—is not favourable to the surgeon, the full capacities of whose intellect are not unfolded without sufficient occasional leisure and thought and retirement, all of which are, in some measure, denied him in our new and over-active world. With you, as with us, but, as it seems to me, not so much with you as with us, the average surgeon of to-day is less a man of thought than a man of action. He is constantly liable to disturbance, either from the particular character of his calling or from the agitation of all around him, of which he soon partakes. He is made to eschew the more meditative habits which would the better fit him to weigh well and to adopt or reject what should be adopted or rejected without reference to authority or without being swayed by the influence, not always safe and reliable, of superiority of position or of condition.

Perhaps at no time in the history of our art have the facilities been greater everywhere than they are at present of

arriving at conclusions which may not be intelligent and of being misled by representations which may not be strictly true. In the few intellectual centres in ancient times opinion was gradually formed in solitude. It advanced in regular progression and from mouth to mouth, as it were. To-day, with steam and electricity and the wondrous and unceasing development therefrom of vast physical agencies men are brought nearer to each other. Truth to-day travels with the speed of lightning, but error also and with like rapidity. Opinion formed in a large centre acts especially on the imagination of those around and more powerfully still perhaps of those at a distance. It does not always convince, but it impresses; and, quoting the words of a classical writer, it has the force of authority rather than of reason, and concurrence in it is not always an intelligent decision but a submission or belief. Our minds are often misled by misrepresentations and they remain misled till other and true representations put them right again. Surgical opinion, in an especial manner, is at first and for some time what seems to be thought by everyone in general and by someone, or perhaps no one, in particular. An opinion hurriedly expressed by eminent or even prominent, or perhaps only self-beguided, authority is adopted; it is propagated, it becomes the opinion of the general body; and although we may have resisted the influence of the individual authority in the first instance we finally succumb to the voice of that general body of which we are constituents—each part having, without perceiving it, perhaps done its share in diffusing truth—it may be in extending error. The views on surgical questions, expressed ere they have been fully considered; hasty reports of surgical cases and premature records of surgical operations—especially if they have been bold and novel—when published within a few days of their performance, are often misleading. Had the publication of so-called successful cases in medical journals for its sole object the elicitation of truth error in time would be of small moment. The haste in publishing enables the operator to send copies broadcast over the land as a bid for like operations. Is the journalist quite blameless in facilitating the premature publication of cases which had left, it is true, the hands of the surgeon or the surgical ward of a hospital to terminate fatally in the hands of a medical practitioner or in a medical ward from the direct, though perhaps not immediate, result of surgical interference? Would that that tutelary deity who is supposed to preside over medical journalism would so ordain that there be a little less hurry, a little less zeal in taking the public partially into one's confidence, and in publishing successes while they are yet problematical. Readers of the journals of both hemispheres have occasionally noticed in yours a greater precision in reporting cases and in stating facts than what obtains always in the western world. You do not so often indulge in unknown quantities and dates, and other circumstances are stated with greater fulness. I have noticed the same features in your discussions. An absence of that precision in America must not, however, be allowed to take from the value of a report. It is due in great measure to the hurry and unrest, the variety of fatiguing work a surgeon is called upon to do and the difficulty, even in cities, of having properly qualified clinical assistance. Outside of well-organised hospitals there are well-qualified nurses for the rich—their services are beyond the reach of the poor—and they append the temperature and pulse chart; but beyond this there is often no record till the case is finally summed up by the surgeon, when the feature of treatment is added. Men of action, who have left and are leaving the impress of their intellect in the more practical departments of our art, have been obliged to search in their visiting list or their day-book, where the more methodical arrangement of your work enables you to be more precise. Sometimes the facts are drawn from memory and, for all that is essential, correctly drawn, though dates and other precise circumstances are often wanting. It is from this hurried manner of reporting cases that doubt is sometimes felt of their credibility when given without reference to minor parts which are not considered essential to their truth. The older members of this Association can recall how the statement was received from America some years ago that a crowbar had been driven through a man's skull without killing him, and how brain matter had been found adherent to the strong bar of iron at a distance of many feet. The number of feet was not given (I cannot give it now), but the statement nevertheless was true, even without the lesser detail of distance. Many of you will remember how little disposed you were to believe that a sponge

probang, charged with solution of nitrate of silver, could be got beyond that watchful sentinel, the epiglottis, and be applied to the larynx. Who doubts it now? The same may be said of Sayre's assertion, discredited at the time, that after excision of the bones of the hip-joint the joint could be so arranged that the little patient could be borne from one place to another and without injury. Many of you have seen Sayre's work.

Were I disposed to dwell on American surgery I could greatly multiply instances of this kind, but that is not my purpose. I shall merely add that it must be apparent to readers on this side of the Atlantic and to those who have visited the western hemisphere that the American surgeon arrives, in his own way and with marvellous celerity, at the chief points in a case—at its gist, its essence, so to speak—by a process which may not be strictly called logical, but which partakes rather of an intuitive intellectual judgment or perception. He seems to recognise truth, or something he takes to be truth, without any elaborate process of ratiocination. This marked quality in the American mind renders him prone to eclecticism, not alone in medicine and surgery, but in philosophy and even in matters of theology sometimes. The relatively greater freedom from death which Valentine Mott, more than half a century ago, claimed for surgical operations performed in New York and Philadelphia I claim, and more advisedly claim, for operations performed in the larger cities of Canada. The inflammations which sometimes follow surgical procedures with us are indeed accentuated and are marked by much elevation of temperature, but the character of those inflammatory processes is of a simpler, plainer, more sthenic type and not of that irritable form which so often perplexes hospital surgeons in the larger centres of Europe. The climate of Canada has much to do with this. In many parts of Great Britain mortality, from all causes, increases with the decrease of temperature; with us it is the reverse. Our winter season, with the temperature of St. Petersburg, is the healthier; spring and autumn come next in salubrity; while the largest mortality is in July and August, when the temperature is that of the same months in Paris. At certain seasons the atmosphere is so dry that the ment of the buffalo and the red deer, when cut into strips and dried in the open air, may be reduced to powder, forming the pemmican which often alone sustains the aborigine in his wanderings. When you add to this condition of climate the simple frugal habits of the people—well fed, well clothed, well housed—where, like Longfellow's Arcadian, "the richest are poor, and the poorest live in abundance," you have a sturdy energetic race who display much power of resiliency when their injuries demand the intervention of surgery. It is, moreover, a people subject to few ailments, and these are of a sthenic inflammatory type. Thorough acclimatisation is found to confer additional immunities. Those who can count the greater number of generations born in Canada are the healthier, while those undergoing the process of acclimatisation do not suffer in the processive state. These remarks do not apply to the descendants of the aborigines who have been allied to the whites. The inflammatory affections met with in the *métis*, whether of the French with the Huron or of the Scotch with the Cree, are for the most part of a strumous type, presenting but few of the characteristics of those affections in the people of either progenitor. There are no surgical diseases in Canada which have not their counterpart in every portion of Europe, two alone excepted, when, in the words of Milton,

"the parching air

Burns froze, and cold performs the effect of fire."

Frostbites are met with (among the non-acclimatised chiefly), and when snow covers the land the *mal de raquette* is complained of by those who suddenly, and without preparation, are called upon to make long and hurried journeys on snow shoes. Aneurysms are not common in Canada; chronic rheumatic arthritis is seldom met with; rickets, which the Germans still love to call, yet they cannot say why, "Englische krankheit," is scarce; strumous ophthalmia, which is so constantly seen in the hospitals of Vienna, London, and Glasgow, is not frequent; and in cancer, especially of the breast, the glandular system is not generally primarily affected, affording thereby a fairer chance of freedom from early recurrence of this disease. I allude to this illness advisedly, as I observe that some of your more distinguished surgeons counsel removal of the axillary glands in all cases of scirrhus of the breast—advice which, from my experience in Canada, I am not disposed to follow.

It is true that on the eastern coast of New Brunswick in

Canada a few lepers are met with in the lazaretto there, but the disease is not indigenous to the soil. Nearly a hundred years ago two shipwrecked sailors were cast ashore at a place called Tracadie. They were the subjects of leprosy. A French-Canadian woman gave them shelter. She washed their linen, contracted that pitiless disease and transmitted it to her children. These marrying, a small colony of lepers was formed. The number was at one time about seventy, but is now diminished to twenty-two, under the care of the sisters of charity from the Hôtel Dieu Hospital of Montreal. Outside those walls there is no disease peculiar to the country. As acclimatisation effects certain changes it affords also certain immunities from which those not similarly circumstanced cannot expect to benefit. The acclimatised bear injuries well. Living in a simple primitive state they require occasional aid from the surgeon and less from the physician. Colonists in thinly settled districts sometimes send long distances for surgical aid in cases of hernia or dislocations. The *ramacheur* or *rebouteur*, as he is styled, is supposed to have an intuitive knowledge of broken bones, and how best to replace them. In dislocations, however, these men are less fortunate; and although their practice is invariably to find a small bone out of joint, which they incontinently proceed to reduce with an audible snap (of their own hidden thumb and finger, be it added) they do not attempt to reduce dislocations of the larger joints. I once had a case of dislocation of the hip of fourteen weeks' standing brought to me a distance of 1500 miles. It took that period of time, after the *rebouteur* had done with the sufferer, for him to reach Montreal in a box like a closely-fitting coffin. The padding was so perfect that movement of either limb or body was thoroughly prevented during a rough journey extending over six weeks. Domestic surgery in civilised countries might in some things learn a little from the primitive methods of our aborigines. For instance, the treatment of the newborn by the latter is judicious. The yielding abdominal walls are never compressed by a unyielding bandage, and the young bird in its nest is not more comfortable. As the varied movements of respiration are not impeded, the infant cries but seldom. It never suffers from the local troubles as the children of the whites often do. The urine is carried beyond the infant's person if a male, by an ingenious mechanical support which directs the stream. Feculent matter is received into dry moss, which is to be found in large quantities in every wigwam where there is an infant. If in the depths of the forest an Indian breaks his leg or arm, splints of softest material are at once improvised. Straight branches are cut, of uniform length and thickness; these are lined with down-like moss, or scrapings or shavings of wood, or with fine twigs interlarded with leaves, if in summer; or with the curled-up leaves of the evergreen cedar or hemlock, if in winter; and the whole is surrounded with withes of willow or osier, or young birch. Sometimes it is the soft but sufficiently unyielding bark of the poplar or the bass-wood. Sometimes, when near the marshy margin of our lakes or rivers, the wounded limb is afforded support with wild hay or reeds of uniform length and thickness.

To carry a patient to his wigwam or to an encampment a stretcher is quickly made of four young saplings interwoven at their upper ends, and on this elastic springy couch the injured man is borne away by his companions. When there are but two persons and an accident of this nature happens to one of them, two young trees of birch or beech, or hickory are used. Their tops are allowed to remain to aid in diminishing the jolting caused by the inequalities of the ground. No London carriage maker ever constructed a spring which could better accomplish the purpose. A couple of cross bars preserve the saplings in position and the bark of the elm or birch cut into broad bands and joined to either side forms an even bed. In this way an injured man is brought by his companion to a settlement, and often it has been found, on arrival, that the fractured bones are firmly united and the limb is whole again. This is effected in less time than with the whites, for the reparative powers of these children of the forest are remarkable. In their plenitude of health osseous matter is poured out in large quantity, and firm union is soon effected.

[Dr. Hingston here showed a femur of an aborigine in which the osseous matter was so profuse as not only to unite the fracture, but to form a bed on which the tuberosity of the ischium was made to rest.]

The healing powers of the aborigines when injured are equalled by the wonderful stoicism with which they bear injuries and inflict upon themselves severest torture. They are accustomed to cut into abscesses with pointed flint; they light up a fire at a distance from the affected part (our

counter-irritation); they amputate limbs and sometimes they amputate their own limbs with their hunting knives, checking the hæmorrhage with heated stones, as surgeons were accustomed to do in Europe in the time of Ambroise Paré, with more *sans froid* than many young surgeons will display when operating on others. The stumps of limbs amputated in this primitive manner are well formed, for neatness is the characteristic of all the Indians' handiwork. The aborigines are familiar with, and practise extensively, the use of warm fomentations. In every tribe their old women are credited with the possession of a knowledge of local bathing with hot water and of medicated decoctions. The herbs used are known to a privileged few and enhance the consideration in which their possessors are held. The Turkish bath, though in a simpler but not less effective form, is well known to them. If one of their tribe suffers from fever, or from the effects of long exposure to cold, a steam bath is readily improvised. The tent of deer skin is tightly closed, the patient is placed in one corner, heated stones are put near him and on these water is poured till the confined air is saturated with vapour. Any degree of heat and any degree of moisture can be obtained in this way. Europeans often avail themselves of this powerful sudatory when suffering from rheumatism. The aborigines have their herbs—a few, not many. They have their emetics and laxatives and astringents and emollients, all of which are proffered to the suffering without fee or reward. Now and then the surgeon of practical trend of mind has opportunity to turn this quality, essential in a new country, to advantage. I could in illustration relate many instances, but shall confine myself to one or two. My predecessor in the surgical clinic, the late Dr. Munro, an eminently practical surgeon, was travelling in a wild part of the country when he was asked to see a man suffering from retention of urine. Munro had no catheter with him, and many miles interposed between him and an instrument and the roads were wellnigh impassable. He looked around the log cabin for something wherewith to enter the bladder, but saw nothing. He noticed, however, that the floor was cleanly swept and that implied the use of a broom. He asked to see the broom. A corn broom was brought to him and with it he soon entered the man's bladder. How? some will ask. With the handle? No. With the corn tops? No. He had noticed that the corn tops were bound to the handle with wire; this he quickly unrolled, made a loop at the free end, and as he unrolled he straightened the wire by putting his foot into the loop, bent a piece, gave the double end a slight curve, and passed it easily into the bladder. The free ends which remained without the body separated somewhat, and the pent-up fluid passed between them. It is not always that the devices which were found to be successful in an emergency are put aside for something which might be better though not so primitive. Some years ago I was present at a meeting of a medical society, not in Canada, 'tis true, but in one of the more western of the United States. A gentleman from one of the large centres had exhibited an instrument for removing foreign bodies from the nose. He extolled its advantages, was applauded, and everything promised well. I noticed, however, a smile on the faces of many present when a small nervous man advanced somewhat briskly to the platform. I wish I could give you anything like a faithful sketch of his manner. His style was sharp, his language terse, and personal pronouns were used most sparingly. He commenced somewhat in this fashion: "Mr. President,—Much obliged to the gentleman from the city. Long distance for him to come to show us this instrument; long distance for us out here to send for one when wanted. Now, when called to see a child with a cherry or any other kind of stone, or a pea, or a bean, or a bead, or a button in his nose, not going to send all the way to the great city for this instrument, and for the professor to come with it—for that's what it means. Can do without both. Wherever there's a boy with something in his nose that has no business to be there, there is sure to be a woman in the neighbourhood, and wherever there's a woman there's sure to be a hairpin. Now, with the boy and his nose and something in it, and the woman with her hairpin and a live doctor and his jack-knife, nothing more is wanted. Now, with the jack-knife, half open, bend the double end, coax this bent end along the roof of the nose, raise the wrist a little, and withdraw with the bent end well down, and if one of the child's toys is there it's safe to come. Wouldn't give that instrument (he had made one while addressing us) for the instrument of the gentleman from the great city, and it don't cost as much money. There's not enough of that in the backwoods for the Professor."

Returning from this digression, although allusion has been

freely made to the primitive manner in which surgery is sometimes practised in Canada, it would be an error to conclude that such is by any means its general state. In the larger Canadian cities surgery in every department is pretty much what it is in the more favoured centres of Europe. There is with us as much refinement in diagnosis, as much dexterity and courage in performing surgical operations, and as much nicety in the technique. All the cavities of the body, brain, chest and abdomen have been explored and the diseased organs operated upon. Canada follows Europe closely, very closely, in all her work. She has had the boldness—may she be pardoned—to precede Europe in some departments of surgery. The tongue and lower jaw were together first removed in Canada; the innominate and the gluteal arteries were first ligatured in Canada; and the credit of the first nephrectomy, which writers give so generally to Germany, belongs to Canada and to Montreal. But why should Canada be in any way behind? The better classes of her students, not content with receiving instruction in their own medical schools, pass one, two and sometimes many years in Europe before commencing the practice of their profession in Canada. London, Dublin, Edinburgh, Paris, Vienna, Berlin are never without a contingent of young Canadian graduates, and, as you well know, many of our medical practitioners periodically visit Europe to add to their stock of acquirements and to renew their zest and relish for professional labour.

The erection of hospitals has in later years been with us the work of individual effort and of private subscription. Hospitals are met with in all large cities in Canada and sometimes even in the smaller towns. The last hospital erected in Montreal—the Victoria—is the magnificent gift of two of her citizens. The first one—the Hôtel Dieu—is the outcome of female love and heroism. The history of the latter is so strange, so unusual, that I may be pardoned if I allude to it at length. When Jacques Cartier returned to France after his discovery of Canada the news of his exploit travelled over France as quickly as was then possible. A French girl, described as young and beautiful, became impressed with the thought that the newly-found country should be the scene of her labours. She succeeded after a time in fitting out a small barque, with money furnished by a Madame Bullion, and with twelve sailors crossed the Atlantic in the spring of 1641. The sea voyage to Quebec occupied three months; it can now be accomplished in one-fifteenth of that time. The journey from Quebec to Montreal by the St. Lawrence, which can now be performed in a night, then occupied eight days. Miss Mance's barque came to anchor at a projecting point off the island of Montreal, then called Hochelaga. Hochelaga was then the *chef-lieu* of the warlike Huron. They looked with amazement at the advent of pale-faced men and one pale-faced woman—for she was alone of her sex. They soon recovered from their surprise, however, and it was necessary for the colonists to throw up as quickly as possible wooden palisades on the land or rear approach; the big canoe, as the barque was styled, was a sufficiently imposing defence in front. If a colonist ventured beyond the palisades to gather fruit or berries or to cut wood he ran the risk of being pierced with arrows. Half of the first colonists perished in this manner and Miss Mance was obliged to go back to France in 1649, returning with other recruits; and again in 1658, leaving France with twenty male and female recruits, half of whom died on the voyage of a form of plague. In their attacks on this small force some of the red men were wounded in return and, when deserted by their comrades, they were brought within the palisades to what they and their tribe considered—according to their own custom in warfare—certain death. They soon found the hospital to be a place of woman's tenderest solicitude. When the red man's wounds were healed a repast of dog's meat was prepared for him and he was permitted to rejoin his tribe to tell what the pale-faced maiden had done for him. It need not surprise us to be told that in the presence of such devotion the warlike Huron soon forgot his ferocity.

A few years later it was necessary for the small colony to move a few hundred yards inland. Word went throughout the Huron camp, and before the hour of departure the aborigines had strewn the ground with leaves and branches of trees and wild flowers, saying the earth was not fit to receive the tread of these women. In this way our first hospital was established, and in this way the light of Christianity was brought to the island of Montreal. Here is how it has been sustained. Miss Mance had obtained from the French king a deed of gift in perpetuity of the small piece of ground where

she had landed, which at that time was valueless. It became, however, in the course of time the centre of the village of Montreal, and eventually the commercial city clustered around it. A century and a third ago, when Canada passed from the rule of France to that of Great Britain, respect was paid by the conqueror to the rights originally conferred by the French king; and the hospital, which at first had but the aborigines for inmates, received within its walls, as colonisation went on, persons of every succeeding nationality. For upwards of a hundred and fifty years after its foundation it alone afforded asylum to the sick and wounded of Montreal. How many from these shores, when sick and disabled, have received maternal care! How many of your children, then, in that then far-off land, have had the pillow of death smoothed for them, and without fee or pecuniary reward! And the same continues to this day; for the property preserved to them by a wise conqueror has, with economy, sufficed for the wants of the institution without municipal aid or Governmental patronage. Between the foundation of this our first, and the Victoria, our last, hospital, other hospitals have been erected—chiefly the Montreal General Hospital, the Western, and the Notre Dame; and all that generosity on the part of the public and zeal and ability on the part of the staff can effect are prodigally bestowed.

In my desire to place before you—and the occasion is so rare—a sketch of what relates to professional life in your greatest colony, I fear I am being beguiled beyond the reasonable and the considerate. I shall turn for a few moments to what you in the Old World and we in the New have a common interest, the division of professional work. There was a time, not yet in the far past, when the human body, in its entirety, came within the scope and purview of the medical practitioner. As the knowledge of cause and effect in medicine became more fully understood; as facts were multiplied and methodically arranged; as the art of healing became so fully developed as almost to permit it to substitute its precepts and rules and directions for those principles which are fundamental, and which belong alone to science; and when morbid anatomy opened a new and practically an inexhaustible field of inquiry, many men gave themselves up almost exclusively to a particular branch or section of medical knowledge, and pursued it with such zeal and ardour—not always, perhaps, for the sake of knowledge, but by some (let us hope not often) for the sake of its productive application—that to synthetise and unite again under a common head parts which have been segregated now seems to be almost impossible, even were it advisable, and for two chief reasons:—1. When in our profession men of energy devote themselves to any branch of knowledge, and apply their minds with continued attention, they cease to realise that, beyond and around them, there are other branches of our art which are of the same origin, which partake of the same nature, and which cannot be divorced from each other without mutual injury. 2. Although reputed pre-eminence in one department of surgery is admittedly a hindrance to advancement in any other department of the same art, and although pre-eminence narrows the horizon around the worker and limits the scope and extent of his work, the one so cribbed and confined within those narrow limits and who obtains pre-eminence within those limits is more surely advanced than is one not so restricted. "The very narrowness of a man's claims," says a classical writer, "by making them definite and appreciable is an advantage. The advantage lies in doing a thing which has a name—an appreciable name—and the narrower is the art, the more appreciable are the degrees of merit in that art." One so restricted, provided he excel in his narrow sphere, "will find himself a privileged man in comparison with the philosopher or the very largest and amplest intellect that ever nature endowed or education expanded."

Nowadays it is difficult for men, even of superior intellect and of liberal knowledge, to avoid being drifted away into one or other of the narrow streams leading into or from the general highway of surgery, and becoming so absorbed in the pursuit of partial truth as not to perceive that it is wanting in many parts; that it is incomplete, unfinished and defective, and can only obtain wholeness when facts are arranged and when phenomena, however distinct they may appear to be, are brought under a common law. No separate department of surgery when isolated from its surroundings for the purpose of inquiry can of itself become an art. I cannot emphasise this too strongly. It is only when the mode of its reticulation with those around it is understood that any particular or special object of pursuit in surgery can hope

to be dignified with the name. Each part, each division, each subdivision—in a word, each speciality—is as the separate clauses in a sentence, which are essentially “architectural parts, aiding, relieving, supporting each other.” As an illustration let me take for a moment the real or fancied disturbances of the functions of certain organs often considered to be the most important of all the organs, compared to which, in the minds of some, the rest of the body (female I mean) is a mere appendage. In many places men have been bold in taking liberties with them, removing them sometimes as if they were of themselves particular or distinct entities, unconnected with or uncontrolled by, and having little relation to, a thinking faculty of mind which readily receives impressions, which is easily affected by sensations and which is quickly disturbed by emotions and passions. Has not quackery gained, has not poor woman lost and has not our profession suffered in honour and dignity by the refusal or neglect of the surgeon to seek for parallelisms and comparisons in other departments of the art? or perhaps, as it sometimes happens with uninformed minds, by the inability to consider any question by a process of mental abstraction, without which science—i.e., knowledge of laws and principles and relations—does not exist. Is it not the tendency of many other departments or segments of our art to take a part for the whole and to give to that part a width, an extent, to dwarf into littleness the limit or exterior line of all other departments? Gentlemen, the exclusion of what is cognate diminishes the value of what is accepted in direct ratio to the value of what is excluded. As the process of analysis has gone on till we can scarcely expect to see it greatly extended, it may occur, it has occurred, to many to ask: Is it not time to hark back upon our course and see if, in the interests of the public even, as well as of our art, a more general synthetising is not desirable, when the approximation of parts which have been divided and which have been kept too much asunder should not be aimed at? As long ago as the second decade of the present century honest John Abernethy, in his remarkably practical essay on the Constitutional Origin and Treatment of Local Diseases, said an evil seemed to him to have arisen “from the artificial division of the healing art into the medical and surgical departments. This division,” says he, “has caused the attention of the physician and the surgeon to be too exclusively directed to these diseases which custom has arbitrarily allotted to their care.” But medicine then was one and surgery was one. What would Abernethy say to-day when each section of the human body is apportioned and allotted, and when, paradoxical as it may seem, each part is often considered to be greater than the whole? Whether a mixed or an unmixed good—and I shall not stop to discuss the question—the art of surgery is becoming more and still more divided into an ever-increasing number of special or particular branches of study or pursuit, each branch having its respective province or domain, which, it cannot be denied, is sometimes kept more distinct by an exaggerated interpretation of its importance. Yet each must ever remain cognate to, and in close relationship with, every other department of the art, for there are no limits or boundaries to their various departments, and a seemingly intimate acquaintance with one and a total nescience of others are crass ignorance of all, for “all are but parts of one stupendous whole,” as the poet puts it. I hope this will not be understood as an expression of a desire to interfere in any way with the pursuit of any particular course, however narrow it may appear to some, however vast to others. My desire is to extend the horizon of each, not to narrow it, and to show that all branches of our art are cognate to each other. So long as there is division of labour there must, indeed, be division of thought; but the narrow limits and boundaries endeavoured to be established are arbitrary. Part is intimately connected with part and a full knowledge of the functions of any part and of its derangements can be had only by those who have a general knowledge of the disposition and arrangement of other parts and their countless and never-ending relations to one another in that wonderfully constructed whole—this body which we inhabit.

In view of what has been said I am impelled to ask, Has the candidate for admission to the study of surgery that mental outfit which would enable him to weigh well the facts and circumstances as they will be presented to him in professional life? Or is it not too frequently the case that his memory has been loaded—overloaded—with material for the most part ill-digested, but with a modicity of knowledge which might be termed liberal, and perhaps, withal, with an absence of logical inference as an instrument of truth.

Memory, however retentive, and stored with facts however great in number, never alone in our profession raised its possessor above mediocrity and retained him there, save when the science of causes and principles was understood, and when philosophy could be invoked wherewith to analyse facts and to place them in relation to other facts which an irrational eye could not see, and which the unphilosophic mind could not understand. Of course I speak not of genius which is trammelled by no law save that which belongs to genius. Never, perhaps, in the history of surgery has the necessity been greater than it is at present to furnish those who are to devote themselves to the art of surgery with an adequate mental outfit, to enable them to say what surgical ailments are by their relations to other phenomena, and to recognise the “consent of the whole constitution with its parts and with other parts which may appear to be remote, but which can never be considered quite separately and without reference to an unfailing sympathy, continuous, contiguous or remote.” Accompanying each part or section of the art in its remotest, most intimate penetral, the facts there gathered, the phenomena there observed, are but segments or fragments of a greater part—of larger phenomena—which the logical mind alone can fairly interpret; for it alone can apprehend these facts and phenomena in their various bearings and relations, in their “strong connexions, nice dependencies,” as the poet puts it.

Here let me say I mean by the word “liberal” not classical, but something more than classical and never without it. It is urged by those who know not or who value but little the advantages which a liberal education confers on its possessor that it is remote from the use and tenour, the needs and occupations, of life, and can be well done without—that its utility is not apparent, that its profitableness is questionable. Looking at the question from a financial aspect—and that aspect obtrudes itself nowadays into every question—a liberal education may be fruitless in money-getting, it may be inconvenient at times when men wish to be untrammelled in their interpretation of the duties of life or may wish to act without reference to any standard of efficiency, or even of honour or of dignity. Physicians and surgeons have, in every country and in every age, been amongst the most learned and the best informed. To-day the difficulty of preserving that distinction is greater than formerly. Education, at one time confined to the few, is now possessed by the many, and while the separation of professions and division of labour tend to the perfection of art, says Dr. Copleston, the same learned authority adds, “but, although the art itself is advanced by this concentration of mind in its service the individual who is confined to it goes back.” Is not the conviction sometimes forced upon us that he was right? It may seem strange to some of you that, coming from a country where schools are thought to be sparsely established and schoolmasters not always easily procured, I should not wish to have the status of classical education lowered. On the contrary, we in Canada would say to you in Great Britain, Elevate your standard of classical attainments and we will raise it with you. Require from aspirants to professional honours that most extensive and varied knowledge which, for want of a better term, we call liberal, and we too shall demand it. We are demanding it now. Acting independently every few years as circumstances permit, we demand more and more from candidates who desire admission to the study of medicine. Within the last two months the Legislature of the province of Quebec has, to English, French, Latin, geography, history, arithmetic, algebra, geometry, *belles lettres* and physics, added philosophy, which with us always embraces logic and mental or moral ethics. This is a step in advance, as that science of sciences “includes, locates, and connects and uses all kinds and modes of knowledge,” and will do much to hold together and keep under control every branch of our noble profession, whose members have in every age been amongst the most cultivated and whose social influence—and commonly for good—it is beyond the power of man to measure.

THE METROPOLITAN ASYLUMS BOARD.—At a meeting of the managers of this Board on Saturday the question of providing another fever hospital for London was discussed. A motion was subsequently adopted that application should be made to the Local Government Board for their sanction, without further delay, to the managers purchasing a plot of fifteen acres of land at St. Anne's-road, Tottenham, as a site for a fever hospital, at a cost of £12,000.

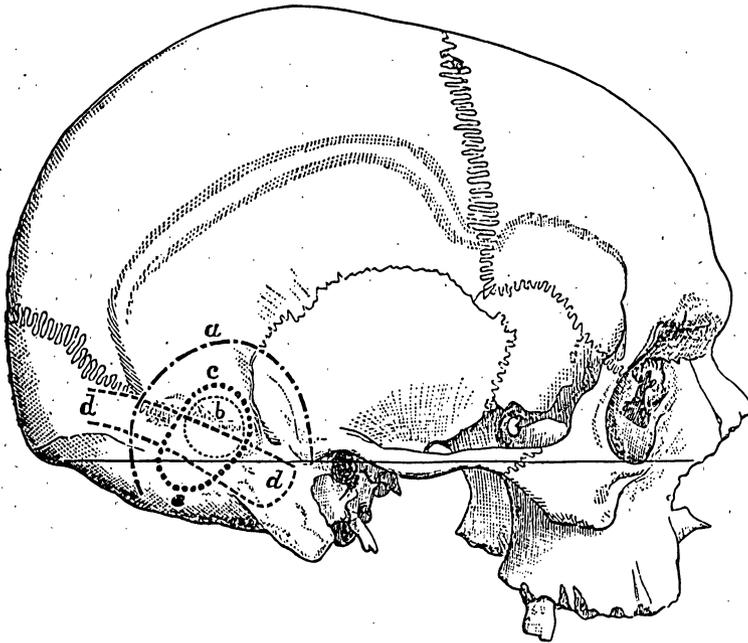

A CASE OF  
CEREBELLAR ABSCESS SUCCESSFULLY  
TREATED BY OPERATION.

By HENRY PERCY DEAN, M.S., B.Sc. LOND., F.R.C.S.,  
ASSISTANT SURGEON TO THE LONDON HOSPITAL, SURGEON TO THE  
NORTH-EASTERN HOSPITAL FOR CHILDREN.

SEVERAL successful cases of cerebral abscess treated by operation have been published during the past few years, but so far as I have been able to ascertain no account of the successful treatment of a cerebellar abscess has been recorded. This fact will, I trust, be a sufficient apology for the publication of a case of cerebellar abscess successfully treated by operation. I believe it is generally admitted that in the majority of cases of abscess of the brain following chronic otitis media it is impossible, from the symptoms, to say whether the lesion is situated in the temporo-sphenoidal lobe or in the cerebellum. This is especially the case when the abscess is on the right side of the brain. In certain cases, however, when the pus is on the left side of the brain, some affection of speech may indicate

and the cerebellum. It should be laid down as a rule that in all these cases the surgeon must be prepared, before commencing the operation, to search, if necessary, both above and below the tentorium. The point recommended by Barker for exploring the temporo-sphenoidal lobe is an inch and a quarter behind and two inches above the centre of the external auditory meatus and for the cerebellum a point an inch and a quarter behind and an inch below the centre of the external auditory meatus. It is clear that these two spots could not be conveniently included in one skin flap and certainly could not be reached by one trephine hole. If, however, the pin of the trephine be placed one inch behind and a quarter of an inch above the external auditory meatus a part of the lateral sinus and the dura mater just above it are exposed. After slightly enlarging the hole upwards with a pair of Hoffman's forceps (the work of two minutes) the dura mater can be incised and an exploration of the temporo-sphenoidal lobe satisfactorily carried out. If the pus is not found the trephine hole can be enlarged for about one-third of an inch downwards and backwards, exposing the whole diameter of the lateral sinus and the dura mater for a small extent below it. By incising the dura mater below the lateral sinus the cerebellum can be easily explored within five minutes of exploring the temporo-sphenoidal lobe.

By referring to the figure it will be seen how small an area

Sketch of an adult skull to represent an operation for treating the chief intra-cranial complications of chronic otitis media. (Reduced to one-half of natural size.) *a*, Line of skin incision; a semicircular flap commencing just behind the pinna, and having a diameter measuring about two inches *b*, Pin of trephine placed one inch and a quarter behind, and one-quarter of an inch above, the centre of the external auditory meatus. *c*, Area of bone removed by bone forceps, exposing the lateral sinus completely and the dura mater above and below it. *d*, The outline of the lateral sinus.

that the temporo-sphenoidal lobe is affected. We are all familiar with instances where that lobe has been explored unsuccessfully and at the post-mortem examination an abscess has been found in the cerebellum, and conversely where the cerebellum has been searched in vain because the pus was situated above the tentorium. In these cases the surgeon has been deterred from exploring both regions probably by several reasons. Chief among them is the fear that the second operation might cause serious shock and perhaps death on the operating table. No doubt also the feeling of disappointment caused by the failure to find the pus at the first exploration has determined some surgeons to abandon the search. If we admit, as I think we must, that in the majority of cases it is impossible to diagnose in which region the abscess is situated the decision not to make a complete search for the pus cannot be justified by any argument. My chief object in publishing this case is to point out that there are no objections whatever to making a complete search for the pus. In every case of cerebral abscess following otitis media the surgeon can, with one skin flap and with one trephine hole, explore both the temporo-sphenoidal lobe

of bone need be removed in order to expose the temporo-sphenoidal lobe, cerebellum and lateral sinus. The operation should not last at the outside more than thirty minutes.

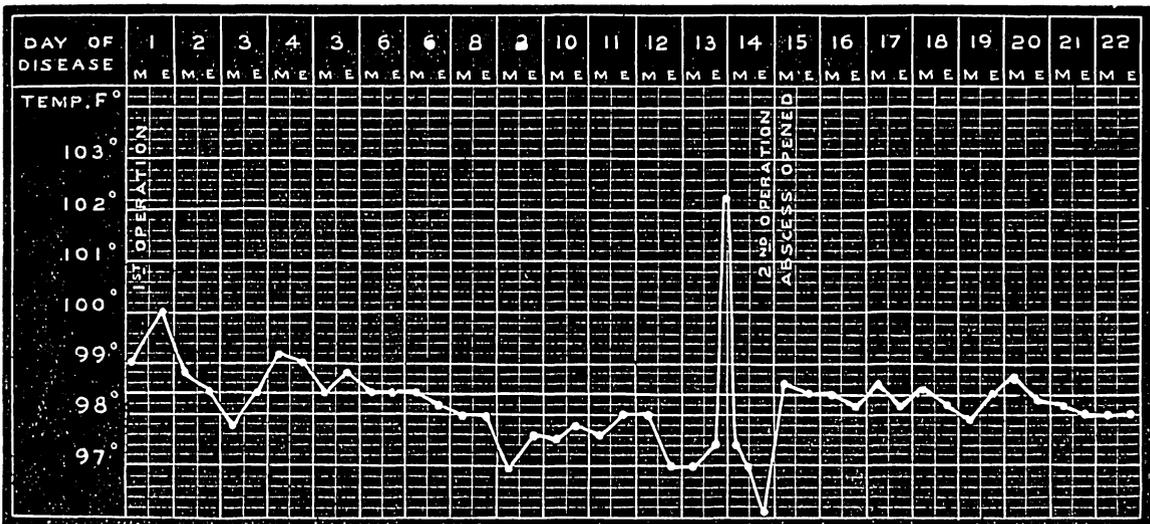

It is well known that in some cases it is impossible to diagnose cerebral abscess from meningitis. In both cases the most evident symptoms are due to cerebral compression, and it may be impossible to say whether the inflammatory exudation is localised or diffused. If after exposing the brain evidence of meningitis is present and no pus can be found, the lateral ventricles should be tapped by inserting a trocar inwards and slightly upwards just above the lateral sinus. It is evident that the only satisfactory way of relieving this pressure caused by the inflammatory effusion of meningitis is to drain the lateral ventricles. The patient is dying from the effects of cerebral compression, and by relieving this pressure the only chance, and that a very slight one, of recovery is given. The symptoms caused by thrombosis of the lateral sinus—"lateral sinus phlebitis," as it has been called—are vague and may easily be mistaken for those caused by abscess or meningitis. Indeed, one of the latter conditions may be present with the lateral sinus phlebitis. It is evident that by the

operation I have just described the lateral sinus can be easily examined. An exploring needle connected with an aspirator, or, better, a hydrocele trocar, can be inserted into the sinus. If blood flows freely from the trocar thrombosis of the lateral sinus can be excluded. I have explored the lateral sinus in this way with a small hydrocele trocar on two occasions, and no bad results have followed. If thrombosis were present, the operation suggested by Horsley and successfully carried out by Ballance should be performed. We see therefore that by a small operation, necessitating but little shock, nearly all the grave intracranial complications of chronic otitis media can be satisfactorily treated, an abscess in the temporo-sphenoidal lobe or in the cerebellum can be drained, the lateral sinus can be explored and the intracranial pressure caused by meningitis can be relieved. It will be noticed in the account of the operation that a small hydrocele trocar was used for exploring the brain and the lateral sinus. It is very convenient and easy to manipulate; if it be thought that the cannula is plugged, the reinsertion of the trocar clears up the doubt. The value of a silver drainage-tube in treating abscesses of the brain I fail to appreciate. An ordinary indiarubber tube adapts itself well to alterations in the size of the abscess cavity as it is healing; it can be easily shortened and is much more readily obtained in an emergency than a silver one.

F. B.—, aged fourteen, was admitted into the London Hospital under the care of Dr. James Anderson on April

examining the right ear it was found that the tympanic membrane had quite disappeared and that the middle ear was filled with flabby granulation tissue. A curved incision was then made over the swelling behind the pinna and a small quantity of pus escaped. With a gouge and mallet the mastoid antrum was exposed and about half a drachm of pus evacuated. The bone was found to be very soft and it was scraped and chiselled away until the dura mater covering the lateral sinus was exposed. It was thought that the lateral sinus might be thrombosed, so a small hydrocele trocar was inserted into it, but blood flowed freely through the cannula, which was then withdrawn. By carefully chiselling and scraping away the carious bone the tympanic cavity was laid open and the granulations scraped away. All traces of softened and carious bone were carefully removed. The tympanic cavity was freely laid open, so that a probe passed in at the external auditory meatus touched one passed in through the mastoid antrum. Antiseptic lotion (perchloride of mercury, 1 in 2000) could be easily syringed right through in a considerable stream. A drainage-tube was then inserted into the tympanic cavity and the wound in the skin was sutured in the usual way. It was thought by Dr. Anderson and myself that sufficient disease was found in the mastoid bone to account for the symptoms presented by the patient.

Condition after first operation.—On the night following the operation the patient slept well and on the next day her condition was much improved. Except for an occasional slight

Temperature chart in a case of cerebellar abscess successfully treated by operation. Notice the marked subnormal character of the temperature for the six days preceding the second operation, also the single rise of temperature to 103.2° the day before the second operation. After the second operation the temperature remained normal. A four-hourly temperature was recorded, but the chart does not show any more features of interest than the morning and evening one.

20th, 1892. The patient had been quite well until five years previously, when she complained of pain in the right ear and this was followed by a "discharge of yellowish matter." Since then the girl has frequently complained of pain in that ear and every few months a discharge has been noticed. The present illness commenced three weeks ago with severe pain in that ear and in the right side of the head, especially in the mastoid region. Dr. Anderson gives the following description of her condition on admission: "Patient extremely irritable and evidently in great pain, shrinking from the lightest touch over the right mastoid process, where the skin is boggy and dusky. She is only partly conscious, addressing her father, who is not present. There is no evident paralysis of limbs, face or ocular muscles. Pupils dilated, equal, act imperfectly to light. There is well-marked double optic neuritis, high myopia, however, making it impossible to estimate accurately the amount of swelling. The right meatus is filled with pus, the left is clear and the membrane fairly normal; knee-jerks normal; no ankle-clonus; heart and lungs normal; no pain or swelling down the right side of the neck." Dr. Anderson asked me to see the case with a view to operation. It was decided to explore the mastoid cells and the patient was transferred to Sophia ward under my care.

First operation.—As soon as possible the patient was taken to the theatre and chloroform was administered. On

headache she continued to improve until April 30th. On April 25th her eyes were examined by Dr. Anderson, who stated that the neuritis was decidedly less marked. On April 30th it was noticed that she was rather drowsy, and that the temperature during the preceding twenty-four hours had not reached 98° F. This drowsiness increased during the following day, and when I saw her at 4 P.M. on May 2nd her condition was as follows:—Patient rather more drowsy than yesterday but answers questions rationally. She complains of slight headache on the right side of the head, chiefly in the mastoid region. No evidence of any motor weakness or anaesthesia could be detected; knee-jerks present, not well marked; no ankle-clonus; no vomiting or nausea. Pulse 64, occasionally intermittent. At noon the temperature was 97.4°. Shortly after I left the temperature was taken and found to be 103.2° (see temperature chart), and the patient then was very (drowsy, occasionally complaining of severe pain in the head. Soon afterwards she commenced to vomit. Owing to a misunderstanding I was not sent for and the patient was not seen by me until the following day at 4 P.M., when the following note was taken. "Patient in a very drowsy condition, and only roused with difficulty; no sensible answer could be obtained. She was frequently sick. Temperature 97.2°; pulse 56, very irregular; respiration very irregular in depth and rhythm. Pupils equal and widely dilated; knee-jerks present; no ankle-clonus." It was evident

that the patient was suffering from grave cerebral compression, and abscess of the brain was strongly suspected. It was decided to operate at once.

*Second operation, May 3rd (fourteen days after the first operation).*—The patient was taken to the theatre and chloroform was administered. Her head was shaved and thoroughly cleansed. A semicircular flap of skin just above and behind the ear was turned down and a periosteal flap was then reflected. The pin of the trephine was placed one inch behind and half an inch above the centre of the external auditory meatus, and a disc of bone three-quarters of an inch in diameter was removed. The lateral sinus was exposed in the lower part and the dura mater above bulged considerably. The dura mater was incised and the brain protruded in a marked degree from the opening. A small hydrocele trocar was then inserted six times in different directions into the temporo-sphenoidal lobe, but no pus escaped. The second time the trocar was inserted the lateral ventricle was tapped and a few drachms of clear cerebro-spinal fluid escaped; but after this the brain did not return to any considerable extent within the skull. It was evident that the intracranial pressure was not due to meningitis or to an excess of cerebro-spinal fluid. As the lateral sinus seemed to bulge more than usual a trocar was thrust into it. Blood flowed freely away, as at the previous operation. It was then decided to explore the right lobe of the cerebellum. With a Hoffman's forceps the bone was chipped away backwards and downwards for half an inch, so as to expose the whole diameter of the lateral sinus and the dura mater below it. The latter was then incised and the trocar thrust in. At the second insertion pus flowed freely away. A large trocar was then inserted and finally a pair of sinus forceps; over an ounce of pus escaped; an indiarubber drainage-tube was inserted into the abscess cavity; the dura mater was carefully laid over the surface of the brain, but was not stitched. The operation was completed in the usual way and the wound dressed with sal alembroth gauze and wool.

*Condition after second operation.*—Immediately after the operation the pulse was more rapid—110 per minute—and regular; the respiration was also regular. The pupils, which just before and during the operation were widely dilated and immobile, became moderately contracted. On the following day, May 4th, the patient's condition was distinctly improved. The wound was dressed and a slight amount of discharge was found. On May 5th Dr. Anderson saw the patient and made the following note:—"Neuritis of left side quite as marked as yesterday, perhaps slightly more so. The right disc on the inner side is also somewhat more woolly, but there are no hæmorrhages as on the left side. Pupils widely dilated; pulse 80, somewhat irregular." The wound was dressed daily and the drainage-tube was gradually shortened. The patient's condition rapidly improved. On May 7th Dr. Anderson made the following note:—"Neuritis of left side distinctly less marked; edge of disc can be easily distinguished; some improvement also on the left side." The drainage-tube was removed on May 10th, and on the following day Dr. Anderson wrote the following note:—"Neuritis in both eyes almost completely subsided; hæmorrhage in left fundus rapidly absorbing." The patient steadily continued to improve, and on May 16th she got up for a short time. On May 19th the wounds of both operations had completely healed up. There was a slight discharge from the ear, which was syringed out daily. On May 30th the patient was quite well. She was seen by Dr. Anderson, who made the following note:—"Both discs are now perfectly free from exudation; edges sharply defined, both of the discs proper and of the staphylomata on their temporal sides: myopia of 9 D. in left and of more in the right; vessels normal, veins perhaps slightly enlarged; pupils and ocular movements normal, except a slight alternating divergent strabismus. V. = J.1 with each eye. H. D. of right ear nil, and of left 1½ ft. Perosseal hearing doubtful. Knee-jerks normal; mental state clear." On May 31st the patient was sent home and told to attend as an out-patient. She was seen last on July 12th, when she was perfectly well with the exception of a slight purulent discharge from the external auditory meatus.

In conclusion, I desire to express my thanks to Dr. James Anderson for the valuable assistance he has rendered me during the progress of the case, and also for the following remarks which he has kindly consented to contribute. "The indications for operation were perfectly clear on the admission of the patient and no time was lost. The pus between the mastoid process and the lateral sinus was readily evacuated and when

Mr. Dean demonstrated to me that the lateral sinus was intact, I considered we were justified in resting satisfied with what had been done. There was marked improvement for a fortnight, but the girl's condition, as the notes show, was never perfectly satisfactory either as to her mental or her physical state, and I have very little doubt the cerebellar abscess was present from the first. I venture to say that the operation devised by Mr. Dean is a distinct advance in cerebral surgery, making it possible in one operation to examine the lateral sinus and to explore the temporo-sphenoidal lobe and the cerebellum. I have twice, for the reason he mentions, given my opinion against a second operation for cerebellar exploration after failing to find pus in the temporo-sphenoidal lobe. In both cases it so happened the opinion was correct, the one being a case of simple mastoid abscess, which recovered; the other a case of meningitis, which died. In both cases, however, I recognise that I might have been wrong and that in both a cerebellar abscess might have been overlooked. My reason in both cases was not that I felt sure there was no cerebellar abscess, but that I dreaded a second operation. The tapping of the lateral sinus to ascertain its condition was new to me. It seems to be a perfectly safe and simple procedure, and it is a very great satisfaction to know that the sinus is intact."

Gower-street, W.C.

## NOTES ON OCEAN TRAVEL FOR HEALTH AND DISEASE.

By JOHN V. SHOEMAKER, A.M., M.D.,  
PHILADELPHIA, U.S.A.  
(Concluded from p. 194.)

THE sufferers from chronic malaria are remarkably improved by an ocean voyage. The congested, inactive liver is depleted and resumes its functions, the sallow hue disappears from the face, the bowels become regular, the swollen spleen diminishes in size, appetite and sleep return and chills and fever cease. Other forms of toxæmia exhibit no less amelioration from ocean travel. In the various manifestations of lead poisoning elimination is decidedly assisted and regeneration of disabled tissues is promoted. A very happy effect is produced in lithiasis and gout. Again and again have I known a patient embark suffering with joint pains and enlargement, disordered digestion and assimilation, an irritable condition of the heart, muscular cramps, headache and insomnia, which vanished almost as soon as the steamer left the wharf. The journey across the Atlantic effected an improvement which endured for months, additionally perpetuated perhaps by a sojourn at one of the spas considered advantageous in gout. These springs no doubt possess a certain efficacy. The water drains the alimentary canal and the liver, which viscus is aided in the resumption of its work in the elaboration of nitrogenous food. I am persuaded, however, that very much of the special virtue of foreign baths consists in the regulated habits there encouraged, together with the superintendence and power of the physicians in charge. The patient, by precept and example, is taught to live by rule. Early and simple meals (served strictly at appointed times), the water taken at specified hours and in specified quantities, the amount and kind of exercise daily prescribed, excess of any kind prohibited—such a system in itself, irrespective of any medicinal virtue in the water, is calculated to reduce lithæmia. As far as the water is concerned, no doubt a number of our American alkaline waters are equally efficacious. We have not yet learned, however, in this country that strict business and professional management of our springs which has been elaborated in Europe. Our people when at home are restless under medical as well as other forms of surveillance and the physicians attached to our springs are destitute of any authority save that which always attaches to their professional advice. For these reasons better results may be obtained at foreign watering-places. And I am of the opinion that, as regards American visitors, much of the benefit thought to be derived from foreign spas is really due to the ocean trip by which the residence is preceded and followed. These remarks certainly express nothing in derogation of the virtues of the various watering resorts, for the management of which I can have

no words but of praise, having known cases of gout to remain markedly improved for many months after such a summer holiday. Patients suffering from diabetes mellitus are improved by ocean travel. I have a vivid recollection of the case of one lady. The patient was passing a large quantity of sugar; she ate and drank with avidity, yet was terribly emaciated and exceedingly weak. All sugar-producing aliments were, as far as possible, eliminated from the dietary, and, as the summer season approached, a voyage to Europe was recommended. The advice was obeyed, the patient crossed the ocean, remained some time at Carlsbad and returned home. The change in her condition was marvellous. Within a few months she had gained more than thirty pounds in weight, the sugar had disappeared from the urine, and bodily strength was notably increased.

On account of its tonic influence upon muscular tissue the atmosphere of the sea is of value in maintaining compensation in valvular diseases of the heart. Ocean travel will delay as long as possible the inevitable occurrence of dilatation. After the cardiac muscle has yielded the value of ocean travel is less decided, and, in fact, may be harmful if the patient suffers from sea-sickness. In the early stage of fatty degeneration of the heart a voyage is beneficial and it may have a favourable effect in angina pectoris.

Among the most impressive cases which it has been my lot to observe was one of functional heart disease, associated with various neuroses. The patient, a big-boned Scotchman, had, from overwork and business cares, fallen victim to a train of nervous symptoms. On being called to see this large man he was found to be reduced in weight to about 100 lb.; he had lost his relish for food, ate but little and digested that little poorly; his bowels were irregular, his head ached, he suffered from vertigo and sleeplessness. The heart's action was forcible, rapid and irregular, and dyspnoea at times so extreme that the affection had been considered organic. The mental condition of the patient was alarming. The temper was irritable, the man was subject to fits of passion alternating with moroseness and there appeared every prospect of the case terminating either in insanity or death. His system had already been deluged with tonics and stimulants of every variety without the slightest avail. Recognising the gravity of the situation, but being firmly convinced that the symptoms, ominous though they might be, reposed upon no organic basis, my advice was, in brief, to "throw physic to the dogs," cross the ocean, revisit the home of his boyhood, breathe his native air and drink Scotch ale. My instructions were followed to the letter. A slow route was selected and two weeks were spent upon the ocean. Four weeks were occupied in visiting his early haunts and two weeks more in returning to Philadelphia. He had left this port on his outward voyage but a few days when improvement became manifest. The heart's action became more steady and less rapid, headache subsided and he began again to enjoy the blessing of sleep. The physical improvement altered his tone of mind radically and for the better. Irritability vanished, he regained his cheerfulness and wanted resolution. This proved the first step in a rapid cure. Upon his arrival in Scotland, already vastly improved, he took pleasure in looking up relatives and old friends, his weight and strength augmenting day by day. When he again reached Philadelphia he felt almost as well as before his severe attack. He has continued well; his occupation keeps him much in the open air; his digestive functions are perfectly performed; his heart is as steady as a clock; his sturdy frame is well clothed with muscle and fat, and he weighs to-day about 260 pounds. This man's life or reason was probably saved by a few weeks upon the ocean. The effect of the voyage was no doubt materially enhanced by the pleasurable emotions arising from a visit to the land of his birth.

An ocean voyage is a valuable boon to one who has just recovered from an exhausting illness. Patients whose innervation has been profoundly depressed by epidemic influenza received signal benefit from a voyage down the coast to Florida and return by sea; the nutritive conditions had, in the meantime, undergone a complete revolution. After an attack of typhoid fever, likewise, a patient may be sent to sea in the confident expectation of rapid gain. Upon the course of acute suppurative processes I have never observed any favourable or abortive effect. If the exciting parasite of suppuration has obtained access to a fit soil for its development the chemical poisons which it elaborates perform

their work on the sea as well as upon land. Still, in the exhaustion due to suppuration a sea voyage is a most prompt and effective remedial agency. The tonic properties of ocean air encourage an active process, while at the same time they communicate resistant power to the system. A speedy termination of the case is therefore indirectly favoured. When, however, a suppurative disease is in its declining stage the restorative and curative virtues of salt air are apparent to the most careless observation. That ocean travel is highly beneficial after pneumonia I have the strongest personal reason to know and it is from this circumstance that my habit of crossing the ocean arose. Fourteen years ago I was seized with acute pneumonia, but upon leaving my bed and essaying to resume my interrupted work in the middle of a college session I found that I was unable to stand the strain. Duties which were not oppressive when in health became painfully burdensome. The air of anatomical and class rooms was unfavourable to resolution of the solidified lung. Cough continued and the sputum was at times bloody. I was compelled to reluctantly admit that I was in a precarious condition and that, unless work was suspended, should find my strength unequal to any task. I accordingly prepared to follow the advice which I had received and left for the south. Travelling leisurely I at length arrived at Jacksonville, Florida. Some, but not much, improvement had taken place and I began to fear that my fate would be to join the host of northern invalids who must flee to the south every winter. At this juncture an elderly physician whose acquaintance I had formed narrated his experience and that of his wife. Like myself he had suffered in the north from pneumonia. Complete recovery being tardy he was induced to go south by sea and found himself eminently improved by the voyage. His wife also, who was the subject of chronic bronchial catarrh, experienced like amendment. As the spring was now approaching I resolved to follow the physician's example. Now, I am not one of those who are naturally fond of the sea. I suffer considerably from sickness and feel much safer when my feet are planted on solid earth than when but a few planks divide me from the heaving main. Consequently, though I embarked I took advantage of the first opportunity to go ashore. I could not fail to be conscious, however, that the trip, short as it was, had done me good, so I summoned up my resolution and took passage upon the next steamer sailing north. Upon landing I went into the country, and when I returned to the city in the autumn I was thirty-five pounds heavier than when I had left for the south. From that day to this I have never had a sign of pulmonary trouble and from that time I date an abiding confidence in the curative virtues of old Neptune. Ever since, when enervated by a hard winter's work, I cross the Atlantic in the early summer, sojourn abroad for two or three months and return invigorated. A laryngitis, to which I have been frequently subject since an attack of diphtheria about twelve years ago, never makes its appearance when I am at sea. Others who are afflicted with laryngitis have experienced the same benefit. What influence has ocean climate upon the course of tuberculosis? To this question it is not easy to give a categorical reply. The individual patient, the stage of the disease, the time of the year, the direction of the voyage, are all elements which must be taken into consideration. In the early stage of pulmonary tuberculosis, when no active change is taking place in the consolidated area, when strength and digestive power are yet fairly well preserved and the patient has not lost much weight, an ocean voyage will often check the progress of the malady. The condition of the mucous membrane is, in my opinion, of some value as an index of the advisability of an ocean climate. If the glands of the gastrointestinal tract are active, the tongue tolerably clean and the bowels regular, it is probable that a voyage will be of benefit. In winter time a voyage in a southern sea—as, for instance, to Bermuda or the West Indies—will often afford relief and hæmoptysis has proved no contra-indication. It is not always possible to predict with confidence that a given case of tuberculosis will be improved by a voyage, but if doubt exists the patient may try the effect of a short trip up or down the coast, according to the season.

The effect of ocean climate is more conspicuous in scrofulosis. The eruptions to which scrofulous children are especially liable, the respiratory and gastro-intestinal catarrhs from which they suffer, are ameliorated by a voyage. The advantages of this therapy are most plainly seen in the glandular manifestations of the disease. Enlarged and hardened ganglia return to normal size and consistence. If caseation

has taken place, healing is rapid after evacuation. When the skin has broken spontaneously and the characteristic, unsightly ulcers with protruding, uneven surface, undermined edges and perhaps fistulae are present, cicatrisation advances much more rapidly, uniformly, and surely at sea than on land. Skin diseases occurring in scrofulous subjects are unusually amenable to medicinal means during an ocean voyage.

I have incidentally, in the course of this paper, alluded to various affections of the skin. Sea air promotes the secretory and respiratory functions of the skin. By removing the underlying and often obscure cause of the affection it not infrequently leads indirectly to subsidence of the disease. In papular and indurated acne the amendment is often very noticeable. The youth who begins his voyage with a blotched visage ends it, to his unspeakable satisfaction, with a complexion comparatively clear. The improvement inaugurated by sea air can generally be continued, by the aid of appropriate therapeutic measures, after the destination has been reached. Various local paralyses are benefited by ocean travel. The remote effects of hemiplegia, such as muscular atrophy and tremor, also receive amelioration. The cause of progressing muscular atrophy will probably be stayed by the same means and the darting pains of locomotor *taxia* may be assuaged.

Social conditions have decidedly limited the power and usefulness of the medical art. Many of our patients are either unable or unwilling to avail themselves of the advantages of physiological medicine. Bound to ill-paid toil, immersed in money getting or pledged to some important undertaking which scarcely permits relaxation, they have no time or opportunity for holidays and cannot go to sea. They demand that, while their conditions of work are unchanged, their systems shall be braced up from time to time by the use of drugs. But drugs, however well chosen, cannot take the place of rest, pleasure and relaxation. An occasional holiday is an economy of time. If time cannot be spared for a trip to Europe, the journey of a few hundred miles along the coast can be soon performed. If money fails, a trip upon a sailing vessel is very inexpensive.

A REPORT ON  
THIRTY-SEVEN CASES OF TUBERCULOUS  
DISEASE OF THE HIP-JOINT,  
FOR WHICH EXCISION OF THE JOINT WAS PERFORMED  
IN THIRTY-SIX CASES.

BY BILTON POLLARD, M.D., B.S. LOND., F.R.C.S. ENG.,  
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL AND SURGEON  
TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN;

AND  
C. F. MARSHALL, M.D., CH.B. VICT.,  
HOUSE PHYSICIAN TO THE METROPOLITAN HOSPITAL KINGSLAND ROAD,  
N.E.; LATE SENIOR HOUSE SURGEON TO THE NORTH-  
EASTERN HOSPITAL FOR CHILDREN.

(Continued from p. 190.)

CASE 12.—N. E—, aged three years. Disease of left hip began at two years of age after a fall; the patient was treated from an early date with a double Thomas's splint. Admitted to hospital eighteen months after the onset of the disease with a discharging sinus at the upper and the outer part of the thigh. The limb was everted, but otherwise in good position. The joint was excised through the anterior incision; head of femur, trochanter, acetabulum and os pubis in front of acetabulum were all diseased. The head and neck of the femur, with a loose sequestrum, were removed; drained with tube. Temperature irregular, but rarely over 100° F. The tube track did not heal. First secondary operation with removal of carious bone in the eighth week after excision; wound healed in six weeks. Recurrence. Second secondary operation eight months after excision; femur healthy, acetabulum carious; wound finally healed ten months after excision. A double Thomas's splint worn for seven months after excision, and single Thomas's splint for twelve months more. When the patient was last seen, one year and ten months after the excision, or one year after the final healing, the splint had been left off for three months. The child was in robust health and the limb not wasted at all. Scars firm; real shortening one inch, apparent shortening

half an inch, the difference being due to slight abduction. Limb could be extended to the vertical and flexed through 45° without movement of spine. Walks fairly well on sole of foot without any support. (Fig. 12.)

CASE 13.—W. R—, aged nine years. Disease of right hip began at seven years of age; no cause assigned. Admitted to hospital two years after the onset of the disease with an anterior and an iliac abscess; limb was shortened one inch and a half, flexed to 45°, adducted and rotated inwards. The joint was excised through an anterior incision; head and neck of femur carious and dislocated backwards; acetabulum covered with granulations; head and neck of femur removed and iliac abscess found to communicate with joint over brim of pelvis; drained for twenty-four hours; temperature never above 100.4°. Wound healed by primary union with a firm scar four weeks after operation; no secondary operations, but the patient was readmitted shortly afterwards for paralysis of the flexor muscles of the foot and anaesthesia supposed to be due to pressure of the splint on the sciatic nerve; a Thomas's splint worn for about eighteen months. When the child was last seen, one year and ten months after the operation, the splint had been left off for about four

FIG. 12.

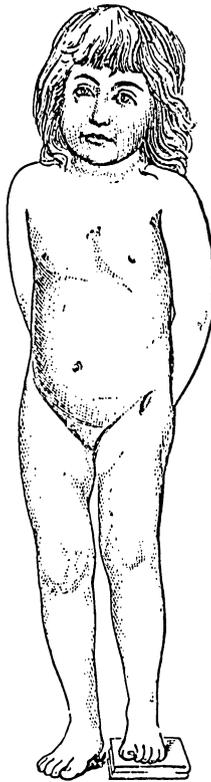

FIG. 13.

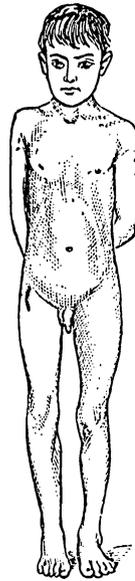

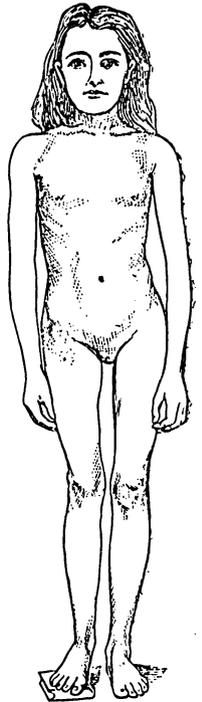

FIG. 14.

months. The child was in good health; scar firm and joint firmly ankylosed in good position without any flexion; real shortening one inch and a half, apparent shortening not made out owing to foot being in a state of equinus caused by paralysis mentioned above. Walks easily without any support. (Fig. 13.)

CASE 14.—E. S—, aged eleven years. Disease of right hip began at seven years of age after a fall; the patient was treated for some time with weight extension and splint. Admitted to hospital four years after onset of disease with abscess in front of joint. The limb was shortened one inch and a half, flexed considerably and slightly adducted. Joint excised by anterior incision; head and neck of femur diseased; acetabulum superficially diseased; head and neck of femur removed; drained for nine days; temperature never above 100.6°; primary union, except at tube track, which healed four weeks after excision; no recurrence of bone disease, but a small abscess, apparently residual in nature, opened fourteen months after excision. A Thomas's splint, worn for thirteen months after excision. When the patient was last seen, a year and nine months after the operation

the splint had been left off eight months. General health fairly good; joint firm; real shortening three inches, apparent shortening two inches and a quarter, the difference being due to slight abduction; limb could be flexed to 45° and extended to the vertical without movement of spine. Walks on sole of foot without support. (Fig. 14.)

CASE 15.—M. B—, aged five years. Disease of left hip began at two years of age; no cause assigned; no treatment before operation. Admitted to hospital three years after the onset of disease with a sinus on the outer side of the thigh. The limb was shortened two inches; flexed 20°; adducted and rotated inwards. Joint excised by anterior incision; acetabulum obliterated by fibrous tissue; head of femur and most of neck destroyed; sequestrum, consisting of head of femur, removed, and joint scraped (operation more an arthrectomy than an excision); no drainage; temperature normal after second week. Wound healed completely. Two secondary scrapings were done two and five months after the first operation; no further recurrence of bone disease; wound finally healed in six months. A double Thomas's splint was worn for fifteen months after the excision. When last seen, one year and six months after the operation, or twelve months after the final healing, the splint had been left off three months. General health good; joint sound; real shortening two inches, apparent shortening one and one-eighth inch, the difference being due to slight abduction; slight mobility of joint. The child did not walk well, but the difficulty in locomotion was dependent more upon weakness of the knee and ankle of the healthy limb than upon deformity of the one which had been diseased.

CASE 16.—F. S—, aged four years and nine months. Disease of right hip began at two years of age; no cause assigned. The patient was treated with a single Thomas's splint for about a year, and a double Thomas's for six months more before operation. Admitted to hospital two years and three-quarters after the onset of the disease with a large anterior abscess. The limb was then everted and shortened one inch. Joint excised by anterior incision; head of femur denuded of cartilage and carious; section of the head showed disease commencing in the epiphysal cartilage and spreading to the surface at one point; acetabulum also extensively diseased; head of femur removed; wound drained for thirty-six hours; temperature never high; wound healed by primary union in three weeks. A Thomas's splint (first double, afterwards single) was worn for twelve months. When the child was last seen, twelve months after the excision, the splint had just been left off. General health was good and the hip-joint and scar were quite sound; real shortening one inch and a quarter, apparent shortening one inch and one-eighth; slight movements of flexion and abduction could be made. This case was too recent to estimate the powers of locomotion.

#### GENERAL STATISTICS OF ALL CASES.

*Age at onset of disease.*—In 1 case the age at onset was between one and two years; between two and three years of age there were 7 cases; between three and four years 4 cases; between four and five years 3 cases; between five and six years 3 cases; between six and seven years 4 cases; between seven and eight years 5 cases; between eight and nine years 3 cases; between nine and ten years 2 cases; in 5 cases the date was unknown.

*Side affected.*—The right hip was affected in 19 cases, the left in 16 cases, and in 2 cases the side affected was not recorded.

*Cause assigned for exciting onset of disease.*—In 10 of the 37 cases the disease was assigned to a fall or blow on the hip; in 1 case the disease appeared whilst a double Thomas's splint was being worn on account of disease of the other hip.

*Duration of disease before operation.*—This was from three to six months in 5 cases; between six and twelve months in 8 cases; between one and two years in 14 cases; between two and three years in 2 cases; between three and four years in 1 case; between four and five years in 1 case; and between five and six years in 1 case. In the majority of cases therefore the duration of disease before operation was between six months and two years; in 5 cases the duration was unknown.

*Situation of abscess.*—In 29 cases the abscess was situated anteriorly to the great trochanter; in 15 of these it was altogether in front; in 14 it was partly anterior and partly to the outer side of the hip; in 3 cases the abscess was behind the great trochanter; in 1 case the situation is not recorded. Two cases had also an iliac abscess, which was found to communicate with the joint through the psoas

bursa. Four cases had discharging sinuses before the operation; 3 of these were situated anteriorly and one posteriorly. The sinus leading from the superficial abscess to the joint was usually found just above the neck of the femur. The abscess had apparently burst from the joint at the posterior part of the capsule and had subsequently passed forwards owing to the resistance being least in that direction. In one case the sinus passed directly backwards to the joint through the Y-ligament.

*Extent of disease at time of operation.*—In the large majority of cases—viz., 35—the head of the femur and the acetabulum were denuded of cartilage and the bone carious to a greater or less extent at the time of operation. In 5 cases the trochanter was also diseased; in one case the acetabulum only was affected; in one case the head of the femur was removed as a sequestrum.

*Nature of operation.*—In the large majority of cases the anterior operation was performed, posterior excision only being done in 4 cases. Of the 33 anterior operations 2 were of the nature of an arthrectomy—viz.: (1) the case in which the acetabulum only was diseased; and (2) the case in which the head of the femur was removed as a sequestrum. In 5 cases an operation was performed previously to excision; in 3 of these the operation consisted in simply opening and draining the abscess; in the other two cases a partial arthrectomy was attempted.

*Period of primary healing.*—Five cases died before the wounds healed. Of the remaining 32 cases, the wounds in 12 healed by primary union in three or four weeks and in 6 more healed by primary union except at the tube track, which granulated in two or three weeks more without suppuration. This makes a total of 18 cases, or nearly 50 per cent. of all cases in which the wound practically healed by primary union. These cases will be considered separately later on. In the other 14 cases the period of primary healing was from three to fifteen months after excision.

*Recurrence of disease.*—In 26 of the 32 cases recurrence of disease took place; no recurrence took place in 6 cases up to the time when last seen (it must be mentioned that one of the 6 died of diphtheria in four weeks and a half after excision). In other words, about 81 per cent. recurred and about 19 per cent. did not recur. In the 26 cases which recurred there was further bone disease in 12 cases, or 37·5 per cent. of the total number of cases (32).

*Secondary operations.*—These were required in the 26 cases which recurred, but in 14 of them, in which no recurrence of bone disease took place, the operations were of a simple nature as a rule and caused but little further pain or trouble to the child. However, in all cases the previous excision of the joint facilitated the secondary operations, for the situation and extent of the former disease were known, or, in other words, the geography of the joint had been learned beforehand. Recurrent disease quickly showed itself at the excision scar, and abscesses, instead of burrowing about and giving rise to sinuses in several situations, came to the surface along the track of the operation wound. This is a point to which we attach importance. A single sinus which leads directly to the joint readily admits of thorough treatment, whilst, if there are many and long sinuses passing amongst important structures, it is extremely difficult and often impossible to disinfect them. Consequently, when excision is performed late in the course of the disease and as a last resource, the wound quickly gets infected from the septic sinuses and prolonged and often fatal suppuration takes place.

*Influence of the operation on the general health.*—Excluding, of course, the cases which died, all the patients were considerably improved in their general health after the operation, and were as a rule quickly relieved from the pain from which they had previously suffered. In only 1 case of the 37 did general infection (tuberculous meningitis) ensue after the operation. One patient developed phthisis soon after his hip was excised, but when last seen, some nine months after he had left off his splint, no signs of phthisis could be detected, and, though still thin, the boy had decidedly improved in general health. In no case did any sign of amyloid disease appear; and, as may be seen from the detailed reports of the cases, amputation was required in none of them, although in several there was extensive pelvic disease.

*The fatal cases.*—The mortality directly due to the operation has been greater than it ought to be. Four, or 10·8 per cent., of the cases died soon after they had been operated upon. In 2 of the cases death was due to shock; with

greater care these deaths might not have occurred. The death of one child was most probably due to too hot water being used for irrigation. The water was very hot, but it was not too hot to be borne by the operator's finger, which was kept in the wound all the time the water was flowing. The pulse, which had previously been fairly good, failed at once and, notwithstanding the most persevering efforts to counteract it, intense collapse supervened and the child died in three hours. This patient was the first on whom we used boiled-water flushing. In another case the operation was too prolonged, owing to an iliac abscess being dealt with at the same time. The child did not rally from the shock of the operation and died in sixteen hours after it. In another case, of which the full notes are unfortunately lost, the death is entered as due to iodoform poisoning. In the absence of the notes our recollection of this case is imperfect, but if the entry upon which we rely is correct, we feel that the cause of death was one which should have been avoided. The fourth patient died from collapse on the eighth day after the operation. He was also suffering from spinal caries and was in a weak and very unhealthy condition before the operation. Four other patients are dead. In 2 cases death resulted from affections in no way connected with disease of the hip—viz., severe and long-standing heart disease in one and diphtheria in the other. One patient died of tuberculous meningitis eleven weeks after the hip was excised. The wound had not healed; it had not been drained in the first instance, and a tube had to be inserted later on owing to distension of the wound with inflammatory exudation. The fourth patient died three years and a half after the excision, the hip being soundly healed at that time. We are informed by the child's mother that death was attributed to abscess in the brain.

(To be concluded.)

## Clinical Notes :

#### TOXICITY OF EXALGINE.

BY REGINALD BROADBENT, M.B., C.M. EDIN.

In view of the fact that exalgine has recently been so highly recommended for neuralgia and allied affections—and I can add my testimony to the fact that it is frequently of great service in facial neuralgia and toothache—I think that the following case should be recorded as illustrating the dangerous symptoms that are sometimes met with. One remarkable fact with regard to this case is the rapidity with which the symptoms occurred, only a few seconds elapsing between the taking of the medicine and their onset.

A patient (male) aged twenty-six suffered from neuralgia over the left temporal region for a week. He was inclined to be anemic. He was ordered a dose containing four grains of exalgine, to be repeated in two hours if unrelieved; and if neither dose gave ease he was directed to take two doses (containing eight grains in all) the following morning after breakfast. The same evening the patient took one dose and obtained relief from the pain, but at the same time complained to his wife of feeling giddy, as if drunk. Next morning at 4.30, feeling a slight return of the pain, he took the rest of the medicine, which contained twelve grains of exalgine. He immediately became dazed, clutched at the bedstead, but fell prostrate on the floor, where he remained quite unconscious for half an hour, and during this time frothed at the mouth. On my arrival at this juncture, I found him on the floor making a feeble effort to vomit. The pulse was feeble and slow; eyes closed; pupils natural. He was with difficulty got to answer questions, when he complained of pain in the region of the stomach and noises in the head. One-tenth of a grain of apomorphia given hypodermically caused him to evacuate the stomach. Subsequently one-five-hundredth of a grain of strophanthin with ten minims of ether were administered in the same way, and the man slowly rallied. The pain in the stomach disappeared first, but the noises in the head remained for some time. Later the patient could not remember events which occurred half-an-hour subsequently to his regaining apparent consciousness,

and during this time he was constantly yawning. He had never had a fit in his life.

Twelve grains of exalgine must be regarded as an excessive dose, but if the toxic dose is three grains for every two pounds of body weight, as stated by some writers, these alarming symptoms ought not to have occurred.

Lelcester.

### SEQUEL TO A CASE IN WHICH TUBERCULOUS DISEASE OF THE KIDNEY WAS TREATED BY TUBERCULIN INJECTIONS.

BY W. GIFFORD NASH, F.R.C.S.

IN THE LANCET of June 6th, 1891, p. 1260, were published the notes of a case of supposed tuberculous disease of the kidney treated by tuberculin injections at the South Devon Hospital, Plymouth, and a further statement of the case was promised. The following is an account of the case since the man left the hospital. Dr. Torbock of Polruan, Cornwall, has very kindly seen the man and examined his urine.

On July 11th, 1891, the patient wrote: "I have no pain at all on passing urine, do not pass it at all by night, nor too frequently by day. I have been working hard since I went home." On May 19th, 1892, he wrote: "I am glad to tell you I am still in good health, only my weight is not increasing. It was 137 lb. when I left the hospital, and is now 133 lb. I have been working hard at farm work every day since I came home. I do not feel any pain in the loins and am free from pain everywhere. I feel as well now as ever I was in my life. I pass my urine very regularly about three or four times a day and once or twice by night. There is no pain on passing urine." Dr. Torbock on May 24th, 1892, wrote: "I have examined P—'s urine. Result: Appearance clear and of natural colour; sp. gr. 1020; reaction acid; no albumen; no sugar." Again on June 15th, 1892, he wrote: "I managed to get hold of P— yesterday. I consider him a perfect cure; no pain in kidneys or anywhere else. He looks and feels healthy and strong, eats, drinks and sleeps well. There are no signs of tuberculous disease anywhere."

Bedford.

### AN UNUSUAL CAUSE OF POST-PARTUM HÆMORRHAGE.

BY JAMES ARMSTRONG, M.B. EDIN.,  
HONORARY PHYSICIAN TO THE LYING-IN HOSPITAL, LIVERPOOL.

HÆMORRHAGE coincident with vomiting during the third stage of labour is a new experience to me. In this case chloroform had been used with benefit during the second stage, and until vomiting suddenly supervened everything was normal. With each effort to vomit there was gushing of blood to an alarming extent in spite of external compression. I offer the following explanation: that the vomiting which was most probably due to chloroform by increasing blood pressure in the abdominal and pelvic vessels interfered with the formation of thrombi in the uterine veins.

Liverpool.

### BIRTH OF A CHILD WEIGHING FOURTEEN POUNDS.

BY JOHN B. HARRIS, M.D. DURH. &c.

THE following account of a confinement which happened in my practice on June 7th, 1892, I think, will be of interest to the readers of THE LANCET.

A few months ago I was engaged by a lady to attend her in her confinement (the sixth), which she expected to take place at the end of April, the menses having ceased on July 17th, 1891. In August her husband went abroad for months. At the commencement of May my patient became alarmed at her condition. There were no signs of coming labour, but her size was then enormous, and it was with the greatest difficulty she got about. From that time she still increased in bulk, and during the last few days she has been obliged to keep her bed. Labour at last commenced at 5 A.M. on June 7th. I was sent for at 9. I found the waters had broken and labour so well advanced that in an hour the head was easily expelled. Then my difficulty commenced, and it was some considerable time before I

could extract the body owing to its immense size. The child (a girl), I am sorry to say, I was unable to save; it died during the birth. I have been in practice twenty-five years and my confinements now number thousands, but I have never had a case like this one for size of child. Its weight was 14 lb. (full); length 27 in.; chest measurement, 15 in.; thigh measurement, 9½ in. in circumference; arm measurement, 6 in. in circumference. I have been able to find records of only very few cases where the child weighed 14 lb. and over, and only one whose length was 27 in. (Dr. Dewees). I may mention my patient has previously had two children, weighing just over 12 lb. Apparently this pregnancy extended to 325 days.

West Norwood, S.E.

### HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

#### ST. MARY'S HOSPITAL.

##### TWISTED SPERMATIC CORD AND GANGRENE OF TESTIS; REMARKS.

(Under the care of Mr. HERBERT PAGE.)

WHILE the subject is fresh in the memory because of Mr. Bryant's recent contribution to the Royal Medical and Chirurgical Society on Torsion of the Spermatic Cord with Strangulation of the Testis,<sup>1</sup> it may be opportune to record a case which was lately under the care of Mr. Page, and which in many of its features was like that related by the former. We have also published notes by Mr. Nash of a case under the care of Mr. Whipple<sup>2</sup> in the Plymouth Hospital. A boy aged sixteen had sprained himself the day before admission, when a swelling in the left groin was present and he gave a history of vomiting. The swelling was hour-glass shaped. "The lower half of this was the left testicle lying in the upper part of the scrotum; the upper, lying over the external abdominal ring, about the size of a hen's egg, was very tense, quite dull on percussion and gave no impulse on coughing." In this case the epididymis appeared to be twisted twice on its own axis, and there was an omental hernia, the piece of omentum being attached to the testis. The testis was removed. Cases of this condition are certainly rare. Some worthy of mention have been recorded by Curling,<sup>3</sup> Jacobson,<sup>4</sup> Johnson<sup>5</sup> and Segond.<sup>6</sup>

A lad, aged seventeen, was brought to St. Mary's Hospital by Dr. MacGeagh on June 4th because of urgent symptoms presumably in connexion with a right congenital inguinal hernia, for which by his advice a truss had been worn with good effect for some considerable time. On the night of June 1st the boy had been awakened by severe scrotal pain, and putting his hand to the part he found it swollen and tender, and thought that the hernia must have come down. He was sick once, and once only, in the morning. Dr. MacGeagh saw him soon afterwards, and found the testis very tender and seemingly swollen. He thought the condition might perhaps be orchitis, although he failed to discover any evidence of gonorrhœa. Fomentations were ordered, and the patient was kept in bed, but, nevertheless, both swelling and tenderness increased and the scrotum itself became red and œdematous. Furthermore, there was constipation and very naturally suspicion arose that hernia and strangulation of bowel might, after all, be the actual state of things. So he was sent to St. Mary's Hospital, where Mr. Silcock, who saw him early in the afternoon of June 4th, excluded hernia from his diagnosis and leaned to the view that some form of orchitis was really

present. The swelling and tenderness of the testis and of the cord, also right up to the inguinal canal, the redness and œdema of the scrotum had by this time very much increased, but it was impossible to say what was the cause of so much inflammation. Once only had the boy been sick. His temperature was normal. He did not look ill, local trouble and pain were alone manifest, and when Mr. Page saw him late the same evening the general aspect and symptoms forbade more than a suspicion of hernia. He therefore laid the swelling open, thinking it clearly the proper course to explore, for, even with all that there was to be said against it, the possibility of a piece of bowel being down could not be put aside. The operation was therefore as for an inguinal hernia, and Mr. Page found the condition of parts that of the congenital variety, with the testis black and distinctly gangrenous and the epididymis greatly swollen and of a deep chocolate colour. Examination soon revealed that this had been produced by torsion of the spermatic cord, which was easily untwisted by two turns to the left—in the direction, that is, of taking out a screw. The site of the twist was at the external ring and there was no apparent cause for it. All the dead tissues were then removed and the open funicular portion of the peritoneum was closed, by ligature. The wound healed forthwith, without rise of temperature, and the boy left the hospital on June 24th.

*Remarks by Mr. PAGE.*—Difficulty in diagnosis was marked in this case as it seems to have been in others of the same kind. Nor could it well be otherwise, for in some respects there was a strange simulation of the symptoms of strangulated hernia, with differences, however, sufficient to create much doubt. The way to solve it was by obeying the rule—when in doubt operate—but yet even without an operation there seems no reason for thinking that the life of the patient need necessarily have been imperilled. Under subcutaneous and presumably aseptic conditions the gangrenous structures would presently have become atrophied and shrivelled and if in the future it had been possible to believe that the boy had ever had a testis on the right side, the singular conclusion would probably have been that in consequence of an acute attack of orchitis, due of course to gonorrhœa, the testis had atrophied and disappeared. It is questionable whether anyone would have thought of a twisted spermatic cord, and yet, as Mr. Bryant pointed out, complete atrophy of the testis may in other instances have thus had origin. How the twist comes I do not know, nor is it easy to explain it. After all it may be purely accidental and of no pathological significance, determined by the wearing of a truss and the frequent manipulation which a hernia and a truss entail. It seems as if some malposition of the testis, either congenital or induced by the wearing of a truss, in association with a congenital hernia, were an essential predisposing cause. One may never again meet with a case of such rarity as this, but it will be an act of strange forgetfulness if another case with like history and symptoms should not raise in one's mind the suspicion of twist of the cord and strangulation of testis. Certain diagnosis is out of the question. There was yet another and wholly different point of much interest in this case. Here was a gangrenous testis and epididymis, much pain and acute tenderness, great swelling and œdema and redness, all the old signs, in fact, of acute inflammation, and yet from first to last there was not a drop of pus in connexion with the gangrenous tissues or with the operation wound. I thank my dresser, Mr. W. J. Harris, for his careful notes of the case.

#### GENERAL HOSPITAL, BIRMINGHAM.

##### A SERIES OF CASES OF CONGENITAL MALFORMATION OF THE LARGE INTESTINE; REMARKS.

(Under the care of Mr. GEORGE HEATON.)

WITHIN the last eighteen months there have been under the treatment of Mr. Heaton four rather exceptional cases of so-called "imperforate anus," and a fifth in which the œcum had been arrested in its progress into the right groin. Cases of imperforate anus and other congenital malformations of the large intestine are not of very frequent occurrence, and two of the cases illustrate rather uncommon varieties of the deformity. It has, therefore, been thought that it might not be without interest to relate them in a series (reserving however, the conclusion until our next issue), illustrating, as they do, some of the difficulties met with in the treatment

of cases in which the left lower bowel is, in a greater or less part of its extent, absent. The clinical histories are as follows:—

CASE 1. *Imperforate anus with probable absence of rectum and descending colon; artificial anus made in left groin; death at the end of six weeks.*—A. B—, a male infant, was admitted into the General Hospital on Oct. 4th, 1891, two days after birth, with a history of having "passed nothing" per anum since birth. Note on admission: The upper part of the body is normal. The fornix is in a condition of hypospadias, the urethra being cleft to the root of the glans. The scrotum is normal and contains both testes, but is situated abnormally near the coccyx. The tuberosities of the ischium are very closely approximated, barely admitting two finger tips between them. In the situation of the anus are two small dimples, one on either side of the median raphe. Chloroform was given and a mesial incision was made into the perineum as far back as the tip of the coccyx. The inside of the pelvis was thoroughly explored for a depth of two inches and a half through the wound, but no trace of rectum could be discovered, nor was any bulging to be detected high up in the pelvis. A left inguinal colotomy was decided upon, but on opening the peritoneum and exploring the left iliac fossa with the finger no trace of sigmoid flexure or descending colon could be discovered, nor could any rectum be felt descending into the true pelvis. The finger was then passed across the child's abdomen and the cæcum felt for on the right side, but no trace of large intestine could be discovered. A distended coil of small intestine was then brought to the surface and united to the parietal peritoneum by six lateral and two terminal silk sutures. After all the sutures had been tightened, the intestine was opened and a free discharge of meconium took place. The operation lasted an hour and ten minutes.

Oct 4th.—The child slept well. There had been no further discharge of meconium and the edges of the intestine appeared dry. A small injection of olive oil was given through the wound, and this was followed in a few hours by a free discharge of meconium.

The child's after history was uneventful. The artificial anus gave no trouble, and the motions, consisting of partly digested milk, were discharged with ease. The child remained in the hospital a month and was then taken home; but it gradually became thinner and finally died of marasmus six weeks after the operation. No colon or sigmoid flexure could be detected by digital examination, but the relatives could not be persuaded to allow any post-mortem examination, and so the presence or absence of a colon could not be verified. It cannot be said that a cæcum and ascending colon were not present in an abnormal place; but the finger, when passed across to the right iliac fossa, could not detect them.

CASE 2. *Imperforate rectum, with penile fecal fistula.*—F. F—, a male infant, was admitted into the General Hospital on Feb. 12th, twenty-four hours after birth, with a history of having passed fæces by the urethra, but none through the anus. There was a well-marked anal depression in the normal position, but the depression lead into a blind cul-de-sac lined by normal skin. Some bulging could be felt high up when the child cried. The tubera ischii were normally situated and the scrotum well forward. On the under surface of the penis, in the median raphe, and about three-quarters of an inch from the end of the glans, was the opening of a fistula, which just admitted an eye probe, and from which meconium was discharged at intervals in small quantities. The child was in all other respects apparently healthy. The urethra appeared quite normal and urine was passed unmixd with meconium from it. On the evening of February 14th the child became uneasy and vomited. On the 15th chloroform was given and a mesial exploratory incision was made at the site of the natural anus, a probe having been previously passed through the urethra into the bladder. The rectum was found three-quarters of an inch from the surface and an opening made into it, allowing a free discharge of meconium. The mucous membrane of the intestine was brought down to the skin on the left side and sutured to it. A small eye probe was then passed down this penile fistula and found to enter the bowel on its anterior surface about half an inch from its blind extremity. The fistula was quite distinct from the urethra, but ran parallel and superficial to it. The child was at once relieved and gained in weight rapidly. The anus showed very little tendency to contract, and the only after-treatment adopted was the daily passage of a small flexible rectal bougie. The fistula remained patent

for some weeks. Suppuration took place at points along it, and after several small abscesses had formed and burst it is now finally closed. The child has been seen at frequent intervals since for infantile syphilis, from which several other members of the family have suffered, and is at present thriving and well.

(To be concluded.)

## Reviews and Notices of Books.

*A Text-book of Morbid Histology for Students and Practitioners.* By RUBY BOYCE, M.B., M.R.C.S. London: H. K. Lewis. 1892.

AN entirely new work upon morbid histology cannot fail to excite attention, for when we recall the great advance which has been made in this department of late years there seems ample scope for fresh writings upon it. It was therefore with more than common interest that we perused the treatise which has been produced by Dr. Boyce, who holds the office of Assistant Professor of Pathology in University College, London. The general plan of the work is rational and systematic. After an introductory chapter devoted to practical directions with regard to the methods of preparation of histological specimens the subject proper is dealt with under two main heads, which may be regarded as "General" and "Special." The chapters of the first division treat of Inflammation, Repair, Degeneration, Neoplasms; those of the second with the morbid changes in each system of tissues and organs. Undoubtedly the most striking feature of the book consists in the illustrations with which it is embellished. These are coloured plates produced from actual photographs, and we can truly say that we have never met with so complete and perfect a series of micro-photographs as those here given. There is no lack of clear definition, and each figure tells, as it should, its own tale. The value of such a collection of faithful reproductions of microscopic preparations must be inestimable to the pathological student. We have drawn attention to this part of the work in the first instance because it would seem as if the author himself intended that his text should be, to a certain extent, subsidiary to the carefully-selected series of preparations which are depicted in the volume. At the same time, it is only right to add that he has not thereby suffered the subject to lack completeness, and that he supplies ample matter which cannot be illustrated by figures.

Devoting a closer scrutiny to the text we note that the author gives a lucid account of the inflammatory process, which is illustrated in the first place by a study of the changes in croupous pneumonia, and then in turn of those in mucous and serous membranes. He uses the terms "croupous" and "diphtheritic" in the sense generally adopted by the German school—namely, as denoting merely two types of exudative inflammation of varying severity, and illustrates this by a preparation from the colon of a monkey in which at different parts of the same specimen these two types may be observed. In speaking of the fate of inflammatory exudates and repair he demonstrates the occurrence of macrocytes having a phagocytic property, and shows how the process of organisation and vascularisation proceeds from the fixed elements rather than from the exuded leucocytes. So, too, he draws a distinction between the leucocytic proliferation and that of connective tissue elements in the process of chronic inflammation, for, if we understand him aright, he attributes to the former the main source of giant cells, to the latter the formation of new tissue. And contrasting by this light the differing fate of the granulomatous formations of tubercle and syphilis respectively, it might be inferred that the virus of the former acts less on the tissues themselves than does that of the

latter. The subject of the Healing of Wounds is clearly stated, and comprises the topics of sponge grafting and the absorption of ligatures. The changes which ensue in muscle, nerve and bone after injury are also discussed, and there is an instructive plate contrasting an uninjured nerve with the peripheral end of a nerve one year after its section. After describing the various forms of degeneration the interesting question of the infective processes is dealt with. Of these we may especially direct attention to the text and illustrations of tubercle and syphilis, which present within small compass the essential features of these prevalent processes. The classification of tumours adopted by Dr. Boyce differs slightly from those hitherto drawn up. He makes four main groups: (a) "Simple tumours and tumour-like hyperplasias of the more highly specialised tissues" (neuromata, myomata, hæmangiomas, lymphangiomas, endotheliomas); (b) "simple tumours and tumour-like hyperplasias of the tissues of the framework" (fibromata, chondromata, osteomata, myxomata); (c) "the rapidly growing and malignant forms of the preceding group" (sarcomata); (d) "epithelial tumours, simple and malignant" (1, of epithelial surfaces, 2, of glands). This arrangement has its merits and also its disadvantages, since it serves to confuse the tendency of growths to become generalised or to remain local with their structure and origin. It is not therefore purely histological. Dr. Boyce does well, however, to treat separately of cysts, of which he has not attempted any genetic grouping. In the present state of knowledge it is perhaps advisable not to make this endeavour. Then follows a highly interesting chapter on Congenital Formations, in which there is a careful collection of examples of formations arising in vestigia or foetal rudiments.

Of the remaining chapters, which are assigned to the description of the lesions in each special system of tissues and organs, the blood and vascular organs are first treated, then the adenoid tissues, after which comes a chapter comprising Addison's disease, myxœdema, acromegaly and diseases of the bones and skin, a conjunction warranted only by the type of tissue which is the most affected in them. Necessarily these last-mentioned subjects cannot be dealt with exhaustively, but as they are rather overlooked by pathologists we may be grateful to the author for noticing them. As regards the rest of the work it suffices to observe that the morbid conditions of the liver are less amply treated in respect to illustrations than those of the kidney, whilst the section upon the changes in the brain and spinal cord is ample and excellent. It should be added that the work is prefaced by an introduction by Professor Horsley, with whose opinion we may coincide that the work is one "which cannot fail to be of much service to the student whether at home or in the laboratory, and of helpful suggestiveness to the original investigator." Lastly, we may highly commend the manner in which the book has been produced; we have already referred to the admirable illustrations, but we ought not to overlook the excellent type and paper, which, although increasing the bulk of the volume, add much to its readability. In a second edition, which cannot fail to be called for as time goes on, a few venial errors of omission and a few crudities of expression which we noted in the text will doubtless be rectified.

*On Contractions of the Fingers and on "Hammer Toe."* By WILLIAM ADAMS, F.R.C.S., Consulting Surgeon to the Great Northern Central Hospital &c. Second Edition. London: J. & A. Churchill. 1892.

In the main this is a reprint of the earlier edition of Mr. Adams's brochure on Dupuytren's Contraction and on a New Operation for Unsightly Depressed Scars. The essay on Dupuytren's contraction is very little altered, but we find some modifications in the after-treatment. The cause of this

deformity is now known to lie in the palmar fascia and its prolongations to the fingers, and Mr. Adams makes out an excellent case in favour of his method of dividing the fascial bands. A chapter is added on Congenital Contraction of the Little Finger or Crooked Little Finger, and Mr. Adams states that this curious deformity is due to shortening of the digital portions of the palmar fascia. When slight the deformity can be overcome by a very simple splint; when more severe, subcutaneous division of the tense fibrous bands in the finger is recommended. The essay on Hammer Toe contains an account of Mr. Shattock's specimens which were shown to the Pathological Society a year or two ago. Mr. Adams attributes the deformity to shortness of the lateral ligaments of the first phalangeal joint, and advises the division of these bands by a fine fascia knife as the appropriate treatment. We think that Mr. Adams hardly estimates highly enough the alternative method of treating this deformity. The chapter on the treatment of conspicuous depressed cicatrices is not materially altered in this edition, but Mr. Adams emphasises the value of the suggestion he previously made.

*Notes on Pathology, a Handbook for the Post-mortem Room.*

By the late R. E. CARRINGTON, M.D. Lond., F.R.C.P. Edited, revised and amplified by H. EVELYN CROOK, M.D., B.S. Lond., and GUY MACKESON. London: H. K. Lewis. 1892.

THIS is a useful little book, compiled by one who had the gift of teaching in no ordinary measure. Students will appreciate its value and be grateful to Dr. Crook and Mr. Mackeson for its production. In systematic fashion and in concise terms the chief facts in morbid anatomy are expounded, so that it constitutes a practical guide to the post-mortem room similar in kind and scope to the multifarious manuals devoted to the subject of clinical medicine. It might perhaps with advantage have been made to include a chapter on the technique of post-mortem examinations and the preparation of histological specimens. For the text itself we have nothing but commendation, although the terseness that characterises the descriptive matter is sometimes a drawback, and despite the fact that it hardly seems in keeping with the purport of the book to include under heart disease some paragraphs referring to its symptoms during life. Dr. Goodhart contributes an introduction, and points out that it is during his studentship that the practitioner has almost the only opportunity of becoming acquainted with the facts of morbid anatomy; he believes that this branch of knowledge is "more inspiring, more instinct with the gifts of a sober self-confidence and of comfort in the many exigencies of the practice of medicine than any" other source of information.

**BEQUESTS AND DONATIONS TO HOSPITALS.**—The late Mr. T. J. Evans, of Brecon, bequeathed £200, free of legacy duty, to the Merthyr General Hospital.—Mr. Edwin Smallwood, late of Redditch, bequeathed £15,000 for the erection and endowment of a Cottage Hospital in that town, and £3000 each to the General and Queen's Hospitals, Birmingham.—The Fishmongers' Livery Company has voted fifty guineas to the Royal Sea-bathing Infirmary at Margate.—Baron de Hirsch has forwarded to the committee of the Royal Hospital for Women and Children, Waterloo Bridge-road, a donation of £500 in aid of the funds.—The authorities of the General and Jaffray Hospitals, Birmingham, have received notice of legacies from the executors of the estate of the late Mrs. Mary Smith, of the Red House Inn, New John-street West, of £250 for the General and £200 for the Jaffray Hospitals.—The workmen of Sir William G. Armstrong, Mitchell and Co. at Elswick have contributed to the local medical charities £259 9s. 7d. for the quarter ending the 30th ult., of which £191 4s. 7d. was apportioned to the Royal Infirmary.—The late Mr. W. Reed, of York surgeon, bequeathed £100 to the York County Hospital.

# THE LANCET.

LONDON : SATURDAY, JULY 30, 1892.

THE thoughtful and suggestive address which Professor CUMING delivered on Wednesday at Nottingham opens up many questions of paramount importance in the study and pursuit of medicine. In the first place his protest against the inclusion of pure science in the medical curriculum is likely to find many sympathisers ; but it is a view which can only be advanced with qualification. No one can gainsay the statement that chemistry has advanced far beyond the limits in which it was confined when the scientific chemist was also the physician ; but this is true of all the sciences. They were in their infancy fostered by the only section of the community that was then cultivating the scientific spirit of inquiry ; and their early steps were guided by men who had attained eminence in the domain of physic. Hence it was that in the schools of medicine alone could either chemistry or botany find a place ; but now that they have an established position of their own and no longer need such fostering, there seems to be more than sufficient reason why they should no longer hamper the medical course. In this matter it seems to us that we are coming to a critical period in medical education, and that it is time to recognise more clearly than is our wont the value to all who intend to embark in a medical career of a sound preliminary training in the elements of the sciences. The system of preliminary scientific studies which obtains in all the Universities should be made general, and the subjects they include should be relegated to a period of the student's career antecedent to his embarking on the professional course, as has been recommended by the General Medical Council. We concur, therefore, with Dr. CUMING in his desire to rid the strictly medical curriculum of such subjects as chemistry and physics, but we do not believe—and he can hardly advocate—that the student should enter a medical school destitute of all previous training in subjects without a knowledge of which physiology would be an irksome, or rather impossible, task. There must be schools of science side by side with schools of medicine, and the training in the former must not be taken as part of the training in the latter. True this change would entail a greater expense on those responsible for the youth who desires to enter our profession ; but if he is to be an efficient member of it, and to hold his own in face of the ever-widening sphere of medical practice, he must build on strong foundations, and the eventual gain will be worth the needful expenditure of time and money.

The main part of the address was devoted to an able review of the present growth of knowledge in the most complex of physiological and medical studies—namely, that which embraces the higher functions of the nervous system. Dr. CUMING introduced this subject by a passing reference to the advances made in our conceptions of cellular pathology and the intimate processes of disease ; and this conjunction of topics at present uppermost in the minds of pathologists, curious as it may seem, yet demonstrates

the vastness of the field which comes under the purview of medicine. His reference to hypnotism was fair and cautious, but he did wisely in not discarding a subject which has the misfortune to be so largely mingled with trickery. Now, however, that its phenomena have attracted the attention of science, it is incumbent on those who study it to do so with purely scientific aims, and in particular to test again and again the allegations that physical changes may take place in the hypnotic state which cannot be induced apart from it. The conditions of modern life and the feverish activity among men to become rich or famous, quite as much as the greater fierceness of the struggle for existence, are responsible doubtless for the increasing amount of functional, nervous, and mental disease in these days. The profession is almost impotent to check this development, since its counsels of temperance in life, thought and action fall on deaf or unwilling ears. Nevertheless, if we cannot control the causes of nervous disease with the power that can be exerted in many another class of human afflictions, we can and ought to cultivate the study of normal mental action to enable us to comprehend more clearly the relationship that exists between the physical and the psychical, and thus possibly to gain some sounder knowledge of therapeutic measures for the mentally enfeebled. Herein we cordially support the arguments of Dr. CUMING, and consider that he has rendered the profession a service by pointing out how much there is still to be learnt in the region of psychical phenomena, and the best method to adopt in their study.

DR. HINGSTON in no way overstated the difficulty of his position in the opening sentences of his Address in Surgery at Nottingham, but he overcame them in so skilful and graceful a manner as to make it difficult to believe in their existence. Avoiding any one special topic he touched lightly and dexterously on many, and with equal wit and wisdom. His text he reserved for the end of his discourse, and few of those who listened to the address guessed how all was leading up to the one conclusion that the whole is greater than a part.

His opening plea for rest was worthy of greater elaboration, especially as in his view there is greater unrest and hurry on the other shore of the Atlantic than on this. There is great danger lest the want of time for calm and patient thought may soon beget the want of inclination for, and even the loss of power of, continuous thought. A replica of REYNOLDS' portrait of JOHN HUNTER might well be hung in every medical school and library in the kingdom, for it would be a silent and eloquent plea for calm and patient thought amid the ever-increasing rush and bustle of life. The mere prevention of hasty judgments, ill-considered opinions and erroneous views would not be the only result of such a frame of mind on the part of surgeons. All their work would be better done. It is a vain regret, however ; and while we reap such a rich harvest of advantage from all the modern discoveries and methods which so destroy mental rest we must be prepared to pay for it in full. Dr. HINGSTON'S defence of Transatlantic medical literature was, so far as it went, just. The local touches, the references to the special difficulties of surgical practice in a new country and to the special traits of character these difficulties create, were admirable and formed an excellent foil to the more

serious treatment reserved for the closing part of the address. Specialism in surgical practice has been a favourite theme with orators and writers, and it is noteworthy that a distinguished Canadian surgeon is as keenly alive to its evils as the most conservative of Europeans. Dr. HINGSTON spoke of it, however, not in terms of unmeasured condemnation. He pointed out that advantages have accrued from specialism and considered that a necessity for it had arisen from the enormous developments of knowledge in every department of medical science. His remarks on the cramping, narrowing and distorting influence of specialism ought, therefore, to receive the patient attention of those to whom they are addressed.

The best part of the address was reserved for the end, where Dr. HINGSTON pointed out the need for a proper mental outfit for every student and practitioner of surgery. The enormous development of the science and also of the art of surgery throws a much greater strain upon the student and heavier responsibility upon the practitioner than was formerly the case. Unless care be taken to prepare the mind for such work we cannot hope to find the strain well borne. How this preparation is to be attained it is difficult to say exactly. Some have recommended the study of science, others of the classics. Whatever it be the mind must be not a storehouse of facts alone, but an observatory and a factory. The student of surgery should never be a mere student of surgery, but always something more—a man who can look at the facts brought before him in their true relation to each other and to the whole; one who can regard even the all of surgery as but a single part of the great whole of life. Some may think it strange that such a call to raise the standard of general education of medical students should come to us from a Canadian; but this fact gives it additional importance. The colonies can fairly ask the mother country to show them the lead in such a matter, and we ought to be able boldly to do so. Something has been done, much more remains to be accomplished; and it will need the help of every discerning man. The immediate and direct influence of education is thought too much of; its indirect effect is valued far too little. We therefore hail Dr. HINGSTON'S closing remarks with special pleasure and satisfaction.

THE proceedings at Spencer House of those constituting the conference summoned by Lord SANDHURST to discuss the conclusions of the Lords' Committee on the Management of Hospitals and Dispensaries are rather significant. The chief conclusion of the Lords' Committee was in favour of a proposed Central Board with various powers and duties, such as the following: To publish an annual report giving a complete statement of the financial position of each medical charity, the sanitary condition of the same, the number of beds used and the number not used; the method of dealing with out-patients so as to secure the coöperation and coördination of all the medical charities; to report on proposals for building new hospitals &c. Such powers, of course, imply those of visiting the various hospitals and dispensaries and auditing their accounts. The Committee, while discouraging the idea of a Government inspector, distinctly recommended that the Central Board should have power to receive endowments, legacies and other contributions for distribution

among medical charities. It is around the proposal for a Central Board that most of the discussion on the work of the Lords' Committee is likely to turn. Already there are two strong diverse views, one for and the other against such a board. Those who are against it say, naturally enough, that it is an invasion of the voluntary principle, on which the whole of our hospital system is founded, and that it would be resented by the committees and subscribers of the individual charities who already give valuable time and money to the present system as a voluntary one. This diversity of opinion found a sort of negative expression the other day at Spencer House. Lord SANDHURST proposed that the conference "should appoint a committee to take into consideration the conclusions arrived at by the Lords' Committee on Metropolitan Hospitals, and to report as to the composition and duties of the proposed voluntary Central Board or such other scheme as may be arrived at after due deliberation." Sir DOUGLAS GALTON suggested that the motion should stop at the words "metropolitan hospitals." Lord SANDHURST adopted the suggestion, and it was agreed to. Of course this does not exclude the proposal from the purview of the Committee; but it gives a clear intimation that it is to have no special attention and has no special recommendation from the conference itself. The force of the objections to such a board is obvious, as well as the delicacy of any central control over free and voluntary institutions. On the other hand, there are strong counter-weighing considerations. We shall say little of the fact that a very intelligent public investigation into the hospitals question at Birmingham ended with a similar recommendation—the formation of a general council representative of all the public medical institutions of the city; nor of the fact that there is practically no alternative proposal for dealing with the difficulties of the situation. We would rather examine some of the plausible objections to the proposal, and then inquire whether they are really so forcible as to preclude a careful experiment in this direction. One great objection is that such a proposal might stop the flow of voluntary contributions. We doubt this. We would point out that under the existing system the flow of voluntary contributions is, if not abating, altogether inadequate to the needs of the case. There are two thousand vacant beds that cannot be used till the sum of £50,000 or £55,000 more is actually forthcoming.

This deficiency does not arise from want of wealth—spare wealth for such a splendid purpose. It arises partly from an impression that there is some carelessness or lavishness in the multiplication and administration of hospitals, which might be corrected by a little control from a friendly central supervising body. Too much centralisation may be a bad thing, but without it there is a tendency to excessive growth and unseemly competition which bring charity itself to pauperism and diminish respect for it. We incline to think that the central body, if properly constituted, would inspire confidence both in the public and in the managing bodies of existing charities, which so nobly discharge a laborious and unpaid duty, and thus lead to an increase in public support. There is another consideration. We cannot ignore what the Lords' Committee point out, that the hospital system of London at the present moment is not altogether a voluntary one. The creation of Poor-law infirmaries and rate-supported Asylums for infectious diseases has altered the position

greatly, and this alteration must be faced. We sincerely trust that nothing will ever obliterate the voluntary hospitals, which are the glory of England; but it is essential to consider that the other institutions affect both the feelings of the poor who use them and the ratepayers who have to support them.

The great thing is that the central body should be well chosen and should be chosen mainly if not entirely by the voluntary institutions of which we are all so justly proud. The hospitals and dispensaries have shown the greatest respect for the Hospital Sunday and Hospital Saturday Funds and have met their criticisms with every attention and desire to make improvements. This would be still more the case if the central body existed chiefly for the purpose of friendly supervision and the prevention of excessive growth of what is already too large for easy support. The proposal to give it powers of receiving endowments, legacies and contributions seems to us one for much reconsideration. It would tend to divert the income of individual hospitals and give rise to much jealousy. We cannot doubt that a central board elected by the medical charities would have their entire respect and might likewise command the respect of the benevolent on whom our voluntary charities depend. We shall await with much interest an expression of the views of the committee appointed at Spencer House, not only on the proposal for a Central Board but with regard to all the conclusions of the Lords' Committee.

THE volume dealing with the work of the Metropolitan Asylums Board during 1891 contains the reports of the Statistical and Ambulance Committees, as well as of the superintendents of the infectious and imbecile establishments of the Board. The Statistical Committee congratulate themselves on the incorporation in the London Public Health Act of 1891 of the amendments to the Notification Act of 1889 that they previously suggested, but still regret that notification does not apply to the royal palaces, barracks, police stations and prisons. The committee further regret that there is no central authority to trace outbreaks of infectious disease or to carry out measures of disinfection and revaccination, and draw attention to the fact that these duties are at present divided between the sanitary and Poor-law authorities of the metropolis, the County Council and the Local Government Board. They suggest that the Managers should petition Parliament to invest such a central authority with power, not only to remove and isolate the sick, but to disinfect "premises, bedding, &c.," to vaccinate those exposed to infection, to investigate the origin of outbreaks and to compensate persons detained in quarantine. These are far-reaching and bold suggestions, and, inasmuch as they seem to have been adopted by the Managers, they deserve more than casual notice. Without in any way decriing the useful work performed and being carried out by the Asylums Board, it is clearly open to objection that the Board as at present constituted could not with any satisfaction cope with the colossal task that the Statistical Committee would set it to do. To concentrate such wide powers in a body which many, rightly or wrongly, consider an administrative anachronism, inasmuch as its members are partly delegated, partly nominated, and in nowise representative of the ratepayers of London, would

be a step requiring the utmost consideration. The Board at present has neither the staff nor the appliances to carry out the several duties suggested, nor has it any responsible medical or hygienic advice upon which to act. Matters of disinfection and vaccination alone would involve the need of expert assistance of the highest kind, and so would questions of detention in quarantine stations, to say nothing of etiological investigation. The Board is in reality not a sanitary authority at all, but a removal and isolation authority. If there is to be any change, it would be altogether easier and more convenient to graft removal and isolation powers upon an existing superior sanitary authority than to cumber a removal and isolation authority with multifarious sanitary duties. Indeed, the suggestion of the Statistical Committee clearly involves the fallacy that cases removed are the only ones that occur. If the Asylums Board were to become such a body as that proposed it would have to take over the whole machinery of notification.

We are glad to find that the Statistical Committee do not agree with the remarks of the medical superintendent of the hospital ships as to the uselessness of tabulating records of the vaccination marks of small-pox cases. They point out that the kind of record was settled in conference with the Local Government Board in 1887, and quote Dr. EDWARD SEATON'S observations upon the value of such records. Dr. BIRDWOOD'S remarks on this subject appear open to grave question. He says, first, that "vaccinated small-pox patients afford evidence of the failure of vaccination to protect small-pox," without any reference to date of small-pox after vaccination, the nature and result of the attack, and the character of the vaccination. Then he minimises the evidence abundantly accumulated as to immunity of exposed persons who are vaccinated. Lastly, he decries measurement of scars, stating "we do not know the rate of growth of scars." Dr. BIRDWOOD is perhaps unaware of the fact that scars of infantile vaccination rarely increase after the third year, so that he should be able to record definite results concerning his vaccinated patients, most of whom will be over the age of ten years at least. It would be disheartening if valuable scientific material of this kind were wasted, and we are glad to find the Managers alive to the importance of the matter. Reference is made to the continuance of errors in diagnosis in cases sent to hospital and to the fact that all the hospitals are now available for clinical study. The need for an additional hospital in the north-east of London and of another convalescent establishment in the south is emphasised.

As regards the reports of the several medical superintendents, nothing of any general scientific interest is recorded, except the continued appearance of diphtheria in scarlet fever patients, which obtained during 1891 in five of the six fever hospitals. This is a subject of great importance, which deserves the attentive notice of the Local Government Board experts. Mr. MANN, of the Eastern Hospital, records nineteen recoveries from tracheotomy out of eighty-two operations, a very creditable record. He adds that in seventeen of these the trachea was undoubtedly invaded. Dr. BIRDWOOD gives some interesting illustrations of the subtle and intensely active manner in which small-pox spreads.

Numerous tables, diagrams and spotted maps are appended

to, and illustrate, the Board's report; they are neatly put together and presented. We notice that the percentage mortality of scarlet fever, diphtheria and enteric fever was lower in 1891 than in any year during the preceding quinquennium. This may reasonably be ascribed to the improvement in the nursing arrangements at the several hospitals of the Board.

A STRIKING example of the haphazard manner in which great questions are treated in this country is the appearance of an important opinion on medical education as an accidental incident in the course of inquiry into London hospital management at the very moment that a Royal Commission is considering how the problem of granting a Teaching University for London can best be solved. Whilst investigating the position and management of the London hospitals the Select Committee of the House of Lords examined the deans of the medical schools and other prominent members of the profession as to their opinions on medical education. The income and expenditure of each school was inquired into and the amount of fees paid to the teachers was also asked. We agree with the Committee that, "speaking generally, the remuneration of the teaching staff is certainly not high." The question of residential colleges for medical students was also referred to, and it would seem from the evidence of the deans of the Middlesex and St. Mary's Hospitals that they are not so popular or so eagerly sought after as is generally supposed. The discipline and general conduct appear to be very satisfactory, for "serious offences inside the hospital itself appear to be almost unknown." With regard to the formation of a central medical university in which anatomy, physiology, chemistry and other subjects should be taught by experts the opinions of the witnesses were of the widest range. Many urged its formation, whilst others took the view that medical teaching could best be carried out by teachers engaged in the actual practice of the profession, as it would then tend towards a practical outcome rather than have a merely scientific and theoretic bias. Most of the witnesses, although opposed to any interference with the larger of the existing medical schools, thought it advisable that some of the smaller ones should be amalgamated, or that there should be some central schools where their students could be instructed in the scientific or non-professional subjects. The Committee evidently are strongly in favour of a Teaching University, for they sum up the question in these weighty words: "The Committee consider it well worthy of consideration whether it would not be advantageous that the medical schools in London should affiliate themselves to a teaching university or organisation after the nature of colleges in a university, with the view to securing first-rate lecturers for the subjects which can be taught in classes as distinguished from clinical instruction." This expression of opinion on the part of their lordships should be brought to the notice of the Royal Commission and not be buried in a blue-book where few persons would be likely to see it or would expect to find it. At the same time it should be remembered that every branch of medical science has now to be taught practically, so that large classes are both undesirable and impracticable. The Committee are in favour of the opening up of the Poor-law infirmaries for

clinical instruction, but they do not suggest any reorganisation of the medical staffs of these institutions, and without some alteration it is obvious that proper clinical teaching cannot be given.

## Annotations.

"Ne quid nimis."

### THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

THE changes which were necessitated in the staff of the Medical Department of the Local Government Board in consequence of the resignation of Sir George Buchanan, F.R.S., and the appointment of Dr. Thorne Thorne, F.R.S., as principal medical officer have, after much delay, at last been effected. Mr. W. H. Power, as was always anticipated, has been promoted to the post of assistant medical officer. The appointment will be received with satisfaction by the many who have followed the able researches and investigations with which his name is associated, and even more so by those who have had personal experience of the valuable and courteous help which he is always so ready to afford to those who voluntarily seek his friendly criticism of their work and conclusions. Mr. Power's name will always be identified with the great progress which has been made in the study of the relation of diseases in man to ailments in the lower animals. Dr. H. F. Parsons has been appointed to the post of second assistant medical officer, and his addition to the permanent medical staff at Whitehall brings with it the advantage of many-sided skilled knowledge on a number of medico-scientific subjects in their bearing on public health. Dr. Parsons' special reports on such subjects as the various methods of disinfection and on epidemic influenza are recognised as standard works, and they show a great capacity for utilising for public purposes information which has heretofore been too widely scattered and too vague to be of practical service. The vacancy in the inspectorial staff which has thus been created has, we understand, been filled by the appointment of Dr. H. T. Bulstrode, who is honorary secretary to the Epidemiological Society, senior assistant medical officer to the Metropolitan Asylums Board hospitals, and an Examiner in Hygiene to the Science and Art Department of the South Kensington Museum.

### "TAKING THE OATH."

BEFORE the next issue of THE LANCET appears the newly elected members of the House of Commons will have met and some members will have taken the oath and their seats. Since the last general election took place the Oaths Act of 1888 has been passed. It allows those who have no religious belief as well as those who believe that oath-taking is contrary to their religious belief to make an affirmation. It also permits those who may prefer to do so to be sworn with uplifted hand in the form and manner in which an oath is usually administered in Scotland. A reference to THE LANCET of March 24th, 1888, page 586, and April 21st, 1888, page 800, will show that this clause is in conformity with the suggestions made by us. Whether this is a case of *post hoc ergo propter hoc* we will not presume to say, but the coincidence is at least remarkable. It was stated recently in the papers that advantage was taken of each new Parliament to have the mace regilded and new wigs supplied to the Speaker and Clerks at the table. Whether a supply of New Testaments and copies of the Pentateuch is also the rule we are not told. But it is probable that the Scotch members might wish to be

sworn as they are in their own country and that many other members might also prefer this mode of adjuration. We reproduce the clause in its entirety:—"If any person to whom an oath is administered desires to swear with uplifted hand, in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question."

#### A TEACHING UNIVERSITY FOR LONDON.

DURING the past week Mr. Watney of the City and Guilds of London Institute; the Rev. Prebendary Wace, D.D.; Sir Joseph Lister and Dr. Priestley of King's College; Sir James Paget and Mr. A. Milman from the London University; Drs. Liveing and Norman Moore on behalf of the Royal College of Physicians; Dr. Dykes, Professor Whitehouse and Dr. Reynolds for the various theological colleges; and Professor Emmett of Baltimore have given evidence. The delegates from the medical schools presented their case on Thursday, whilst there are many points of individual difference in opinion, they are agreed that (1) degrees in medicine should not be placed beyond the reach of the majority of their students; (2) that the teachers should have greater control over the curricula, syllabuses and arrangements for examinations in medical subjects than they at present possess; (3) that either a purely local university for graduation should be established, or that if a modification of the existing University of London be recommended no modification would be satisfactory which did not provide for the granting of degrees restricted to London students and under the substantial control of the London teachers. The London schools of medicine would also claim recognition and representation in any new or remodelled university, and they would ask for a share equal to that of any other faculty in the government of any such university. These demands seem to us to be absolutely prohibitive of any "professorial" scheme, in which the governing bodies of the medical schools would have no direct influence or power. The following are the names of the delegates who were examined on Thursday:—Dr. Shore (St. Bartholomew's), Mr. Stanley Boyd (Charing-cross), Dr. F. Taylor (Guy's), Dr. Dickinson (St. George's), Mr. Page (St. Mary's), Dr. Coupland (Middlesex), Dr. Payne (St. Thomas's), Prof. Schäfer (University College) and Mr. Spencer (Westminster). Mr. Stanley Boyd gave evidence as principal witness on behalf of the schools, and was followed by Prof. Schäfer, Dr. Dickinson, Dr. Shore, Mr. Page and others.

#### BURIED ALIVE FOR SEVENTEEN DAYS.

THE teaching of experience as illustrated by several recent instances of prolonged abstinence, though it may afford some idea of human endurance in this particular under special conditions, has yet provided no certain criterion of the vital resistance possessed by the average man when suddenly deprived of every form of sustenance. The measure of this force may nevertheless be gauged with approximate correctness from the history of recurrent instances of prolonged and accidental privation. As an example the following is remarkable even in this category. It is the narrative of three Bohemian miners who after being entombed by a fall of sand in the pit where they were working were finally rescued alive, though of course in an utterly prostrate condition, seventeen days later. During the period of their live-burial air was pumped down to them by bore-holes. On this they may be said to have lived without food and without water. The total want of the latter is what makes their survival so remarkable. But for this essential the longer fasts of professional fasting men would have been quite impossible. We can have no difficulty in understanding generally why this holds true if we bear in mind the fact that not only does water constitute by far the greater constituent of every tissue, but that without its due

proportion the circulation and nutrition of the blood and that needful if costly chemical change upon which all tissue repair depends would be alike impossible. In endeavouring to trace the *rationale* of a life persisting, as in the case of the buried miners, in spite of the absence of every natural condition we must notice one or two significant points. In the first place their condition was that of rest, their functional metabolism being proportionally less active, their waste of tissue diminished and their output of carbonic acid not so likely to overcharge the surrounding atmosphere. Further, we may take it for granted that a robust physique had no small share in the conservation of vital energy. Much depends in such cases on the amount of nitrogenous matter stored up, for the most part in muscular tissue, and available for destructive changes. We may safely assume that the amount of reserve nitrogen in the case of these men was not meagre. It is mainly, no doubt, to this circumstance that we must attribute, not only the fact of their existence, but the still more remarkable prospect of their convalescence and ultimate recovery.

#### "LIFEBOAT SATURDAY."

THE chairman of the Manchester and Salford Lifeboat Saturday Committee has made an appeal in *The Times* which appears worthy of attention by those who are interested—and who are not?—in the welfare of all "who go down to the sea in ships and do business in great waters." Lifeboat Saturday in Manchester and Salford resulted, we are told, in October last, in the raising of no less a sum than £5500; and Liverpool, Bolton, Oldham and Stockport have already followed the excellent example set by the first-mentioned northern cities. There is no reason apparent to us why so admirable a movement as that already started should not become a national institution like that of Hospital Sunday. True, the classes to be benefited in the two cases are diverse, but the relief of the destitute sick and the rescue of those in peril of shipwreck are objects which should equally command the sympathies and aid of humanitarians of all grades in society.

#### INFLUENZA IN NEW SOUTH WALES.

WE have received the official report on the Epidemic of Influenza in New South Wales during 1891 of the Chief Medical Inspector, Dr. Ashburton Thompson, to the President of the Board of Health, Sydney, dated May, 1892. This is a welcome addition to the history of influenza. The large area of the province invaded and, excepting in the capital, its sparse population show—in Dr. Thompson's words—"upon evidence sufficient to convince that the spread of influenza was by slow degrees, both over the metropolitan district regarded as a place by itself, over the larger towns considered as places by themselves, and over the country as a whole; and that it was in every respect accordant with what was known to be the habit of the communicable diseases." This conclusion has a foremost place in the report, opposing some old statements in the preamble of influenza spreading on the wings of the wind, of large districts suddenly invaded, of pandemic extensions due immediately to atmospheric changes; yet Dr. Thompson begins by saying—"The pandemic which began in 1889 reached New South Wales in 1890." The use of this term, though fairly represented in the sequel, is misleading, as two cases are reported from the remote village of Hillston in July and August, 1889, one at Albury before Dec. 10th, and one case in Sydney on Dec. 25th, 1889. The disease started as an epidemic in March, 1890, and took from ten to twenty-two weeks in its deliberate spread. As with us, a recrudescence of the disease occurred in the following year from July to October, 1891, but instead of beginning in Sydney "some places in the country began to suffer before the capital," supplying cases to the middle of August, while the reports from the metropolitan district stand blank. The report continues: "The new con-

flagration may in some country districts have relighted from embers still smouldering there unobserved; but the more extensive outbreak again followed that of the capital in a way to suggest connexion between the two such as would be expected in the case of an infectious disease by one acquainted with local conditions of trade &c." The disease subsided in November and again during the following April there was slight recrudescence. The seasons, though the reverse of ours, seem still related in some way to the prevalence of the disease. Whatever the condition of the air, the presence of an infecting particle is assumed throughout the report as necessary to influenza and the conditions under which it acts are well discussed. "A special mode of communication must be inferred, as proximity, though it may be necessary, is insufficient by itself."

#### SLANDER OF A MEDICAL MAN IN BANFF.

THE *North British Mail of Glasgow* contains a report of an action in the First Division of the Court of Session before the Lord President and a jury, brought by Dr. Barclay of Banff against Mr. Robert Duncan, merchant, of Banff, for £1000 damages for alleged slander. The plaintiff had practised in Banff and held various medical offices there since 1863. He was one of the visiting surgeons of Chalmers' Hospital, but owing to differences with the officials he had resigned, and sent his resignation to the defender. The pursuer complained that the defender had on various occasions slandered him by stating that he was guilty of using indecent familiarities with the nurses in the hospital, and that these statements were false, malicious and calumnious. In the course of the evidence it appeared that the word "familiarities" had been used with all its mischievous insinuations, but under cross examination the defender said he did not believe there was any "impropriety" on Dr. Barclay's part. The pursuer's manner was known to be frank and fussy. It is certainly rather hard on a respectable man, even if a little frank and fussy in manner, to be charged with "familiarities," and we are glad that the verdict was given to the pursuer, with damages at £200. The defender was let off mercifully, and will perhaps learn to speak with more caution where the character of medical men is concerned.

#### A SERIOUS NUISANCE.

HAMMERSMITH has been suffering from a serious nuisance. The owner of a piece of land has been engaged in digging out and selling gravel from it; and, the land being near the river, water has filled the hole which has thus been created, making a pond containing from one and a half to two million gallons of water. Into this pond has been pitched the refuse of the neighbourhood and this decomposing has poisoned the air with foul odours, which have driven those resident in the vicinity of the pond from their homes. How this has been permitted to occur is not evident, but the fact remains that a gigantic nuisance has been created which deserves all the condemnation it has received at the hands of angry rate-payers. When the nuisance had become patent the vestry of Hammersmith held an "emergency meeting" and served a notice upon the owner, calling upon him to abate the nuisance within seven days. The County Council then became cognisant of what was taking place and made inquiry into the matter; but the vestry, having instituted proceedings, were not in default, and the council, like everyone else, has to wait the result of the action of the vestry. In the meantime a correspondent of *The Times*, whose vexation evidently makes him ignore the fact that the council is limited by the terms of an Act of Parliament, attacks the council and the vestry alike, and later solaces himself with the statement that his published letter was the means of making the council undertake a duty which it was quite im-

possible they could perform before the vestry was known to have failed. The owner of the pond has now proceeded to take steps for the abatement of the nuisance and men are engaged in pumping the offensive water into the sewer, and in filling in the pond with earth. If his efforts should prove insufficient or should in any way relax the vestry must obviously summon him before the magistrate and this we anticipate they will not be backward in doing, for the eyes of the public are upon the Hammersmith vestry, and no sympathy will be felt for a sanitary authority which does not use all the powers it possesses for removing from its district so serious a menace to the public health.

#### CENTENARY OF "THE RETREAT" AT YORK.

A HUNDRED years have elapsed since the foundation of an Institution for the Insane which has excited admiration in all interested in their welfare, whether at home or abroad. The Medico-Psychological Association held its annual meeting at York this year on July 21st, to mark its appreciation of an event so beneficent in the reform of the treatment of the insane. The medical superintendent of the Retreat, Dr. Baker, was appropriately elected President on the occasion. Dr. Yellowlees moved a resolution, which was unanimously adopted, expressing the Association's warm appreciation of the work effected by the founder, William Tuke, and his fellow-workers in regard to this remarkable asylum, where chains were unknown at a time when it was supposed they could not be discarded with safety, and where gentleness and consideration were substituted for inhumanity and empiricism. The inestimable benefits conferred by the philanthropic and far-sighted founder well deserve the recognition it has just received in so striking a manner in the place of its birth. A very remarkable feature of the occasion was the number of congratulations which poured in from the psychological associations of America and Europe. The English, Scotch and Irish boards of lunacy paid a high tribute to the movement in the interests of the insane commenced in 1792. A highly interesting circumstance occurred at the meeting at York. The great-grand-nephew of Pinel, Dr. René Semelaigne, was present to speak for his nation and his family. It was a happy international recognition of benevolent action common to both countries and was responded to by Dr. Hack Tuke's proposing the health of the French physician, which was duly honoured. Belgium was worthily represented by Dr. Morel of Ghent, the President of the Medico-Psychological Association in that country.

#### THE PROGRESS OF CHOLERA IN EUROPE.

CHOLERA continues to make steady headway in Russia and we have now reached a stage when even the incomplete official returns admit about 1000 fresh attacks and some 550 deaths per diem. It is possible that south of the Caucasus the disease may have somewhat diminished, but, on the other hand, the disease has spread westwards round the Sea of Azov and to Kertch, and it is also reported to have invaded Roumania. No details are as yet to hand as to this last invasion, which, if true, is of serious import to Europe. A further extension of cholera northwards and along the branches of the Volga has also taken place, and at last there is no question as to the prevalence of the disease in Nijni-Novgorod, where the preparations for the great fair and the subsequent dispersion of caravans may serve as a medium for distributing the infection such as will be beyond control. The German Government are evidently very anxious as to their eastern frontier and their Baltic ports. At each such port and at frontier towns where traffic crosses the boundary inspection stations have been established and it has been decided that such articles as used linen, old clothes, rags &c., shall not be admitted. Some check seems also intended as

regards the emigration which is now going on from the western provinces of Russia. Prussia is also watchful on her eastern frontier, Paris being in this case the centre of suspicion. This suspicion must also be shared by us, for no proper account has ever been issued as to the actual cause of the cholera which has been going on in the northern suburbs of the French capital, and some of the official records have come to a standstill since alarm became general. In the suburbs the disease seems for the moment to have distinctly subsided in severity, and we earnestly hope that this abatement may be maintained. On the other hand, we have an account of Dr. Brouardel's inspection of the asylum at Chartres where forty patients have been attacked, of whom twenty are stated to have died within a week. One report says emphatically the disease is cholera nostras, but so long as half the people attacked die it matters very little what name be given to the cholera, whether in the Paris suburbs or at Chartres. For a similar reason we can attach but little importance to the announcement which comes by telegraph to the effect that Dr. Proust reports, "there is in France ..... no invading or imported cholera." We fear all Dr. Proust's utterances are not published, and under any circumstances the cholera which has prevailed is very fatal and hence very serious. We trust no invasion may ensue. And as regards importation, we shall look with great interest to Dr. Brouardel's and Dr. Proust's further announcements. They are both recognised authorities and their untrammelled utterances will be of the greatest value. One of the most remarkable features of this occurrence of cholera in France is the apparent absence of any history of importation. But the disease began in a district where cholera prevailed in 1884, and it may be either that the present outbreak is a recrudescence after a singularly long interval, or else that there is some history of comparatively trivial occurrences of a like sort in and about the same suburbs in past summers, and that these occurrences have served as a connecting link between the cholera of 1884 and 1892. This might explain the comparative feebleness with regard to diffusion which a somewhat exhausted infection would be expected to display.

#### THE SOCIAL EVIL.

By a coincidence the first lesson for the morning service on July 27th which generally comes in the height of the London season and which this year fell on a Wednesday is the seventh chapter of the book of Proverbs. It is the chapter which describes in stern language relieved in parts with beautiful passages the scene between the young man void of understanding and the woman with the attire of a harlot. It is terribly significant of the persistence of prostitution that the description of the sight witnessed by Solomon "in the twilight in the evening, in the black and dark night," nearly 2900 years ago should be read in our cathedrals and churches in the morning and be reproduced in our streets the same and every evening almost to the letter. The wise man endeavoured by warning to induce the young men of his day to adopt wisdom and to avoid vice. In the pages of THE LANCET similar advice has been frequently given, and the high moral tone adopted by Sir William Jenner, Sir James Paget, Dr. Gowers and many other leading physicians and surgeons must have its effects upon the present and future generations. It is the more necessary to repeat this since many excellent persons of both sexes have been too ready both to state and to persist in stating that young men have had medical sanction for believing continence to be dangerous to health and incontinence justifiable on physiological grounds. George Herbert's words, "Continence hath his joy," is not merely a poetical effusion, but a sober truth, of which most medical practitioners have both positive and negative evidence. The excellent advice given by the manly

author of "Tom Brown at Oxford," that "the best thing to do with wild oats is to put them into the hottest part of the fire and let them burn there," should be taken in conjunction with Sir James Paget's words, "Chastity does no harm to mind or body, discipline is excellent; marriage can be safely waited for." While heartily re-echoing these grand words we still lament that more is not done by legislation to remove temptations from young and thoughtless men who are compelled by their avocations to pass along the streets at night. That the streets should be permitted to remain the happy hunting ground of aggressive prostitution is an evil which cannot be justified, and calls loudly for vigorous measures of repression.

#### ESCAPE OF A SCARLET FEVER PATIENT.

LAST week we had to comment on the escape of a patient suffering from small-pox from a hospital for infectious diseases. This week a similar incident is reported at Aberdeen. A boy eight years old, suffering from scarlet fever, the day after defervescence, and while desquamation was going on actively, was restless and unruly, and was allowed by the staff nurse of the Aberdeen City Hospital to go to the lavatory at the end of the ward. As he did not return he was looked for, and it was then found that he had managed to escape by lowering the upper part of the window; the opening being at least seven feet and a half from the floor and the walls perfectly smooth. After freeing himself from the ward he succeeded in scaling a wall about nine feet high. The moral of such incidents is obvious, but it still needs to be pointed. Patients with exanthematous disease are not to be held responsible for their actions and nurses should allow them only that liberty which is sanctioned by their medical attendants.

#### GLANDERS IN MANKIND.

THE dangers attending the prevalence of glanders in horses in London and other parts of the United Kingdom have been brought prominently before the public by an inquest held before the coroner for the City of London last week, at St. Bartholomew's Hospital, on a woman aged twenty-four years, the wife of an ostler, residing at Compton-mews, Brunswick-square, who died at the above-mentioned hospital from this loathsome malady. There is nothing extraordinary in people dying from this essentially equine disease, and the only wonder is that more cases are not recorded considering the extent to which it prevails; the only matter of interest is in the way in which infection is supposed to have taken place, if we may judge from the evidence given before the coroner. It appears that the husband, wife and two children occupied two rooms over stables in the mews and in one of these stables horses were taken ill about a fortnight previously. The illness from which they were suffering was stated to be farcy (or skin glanders) and two of them were subsequently destroyed because of being so affected. The woman had nothing to do with the stables, but it was suggested that she might have become affected through using water conveyed in a pail upstairs from the stable. The house physician of the hospital was of opinion, when stating that the woman had died from glanders, that using water from a pail that had been contaminated by a glandered horse, if she had a superficial wound, would be sufficient to impart the disease. The use of public watering-troughs in London has long been suspected of spreading this disorder among horses, and it has been often suggested that resort to these should be prohibited until glanders is suppressed; but up to the present nothing has been done to ascertain whether there is any foundation for such an accusation against these refreshing places. We have already complained of the very perfunctory and lax manner in which this dangerous and destructive disorder is dealt with by the Government and the

great harm that results from considering 'glanders' [and farcy as different maladies, instead of two forms of the same disease, each equally infective and damaging. It is high time more energy and intelligence were displayed and this is rendered more palpable by the statement made at the inquest alluded to by the house physician that there was then another woman in the same hospital suffering from the same complaint. There is only too much reason to apprehend that not a title of the cases of glanders occurring among horses, in London and the provinces, are reported to the sanitary authorities.

#### LOCAL EPIDEMICS.

**DIPHTHERIA**, which had been prevalent in Heywood and which had been brought under control during the closure of the elementary schools, has, according to Mr. H. Wisken, the medical officer of health, reappeared soon after the resumption of school work, the disease being somewhat fatal in character. At Eccleshill, adjoining the borough of Bradford, measles is so prevalent that an epidemic diffusion of the disease is anticipated; and at South Kirby enteric fever shows a tendency to increase in connexion with a faulty and deficient water-supply.

#### LONDON DUST.

We commented some time ago on the decision of Mr. Justice Grantham in a case which came before him, and in which the owner of a house in Essex-street, Strand, claimed damages from the Strand District Board of Works for injury to his health, which it was alleged had resulted from the non-removal of dust. The plaintiff relied upon the provisions of the 125th section of the Metropolis Local Management Act of 1855, which requires the local authority either to remove the dust or contract for its removal, and Mr. Justice Grantham held that the responsibility of ensuring the removal lay upon the defendants and awarded the plaintiff £75 damages. From this decision the District Board appealed, and Lords Justices Lindley, Lopes and A. L. Smith have now reversed this decision, holding that the District Board had sufficiently discharged their responsibility in contracting with someone else to do the work. London householders would have much reason to regret this conclusion of the case if the Public Health Act had not already come into force and provided a remedy which is evidently more valuable than that which existed before.

#### AN INTERNATIONAL MEMORIAL OF SEMMELWEISS.

A PRELIMINARY meeting was held on Monday at the residence of Sir Spencer Wells, who occupied the chair, at which it was agreed to call a general meeting in October to consider the best way of promoting a memorial of Semmelweiss and his great services to humanity. There were present Sir Joseph Lister, Dr. Priestley, Dr. Playfair, Dr. Graily Hewitt, Dr. Glover, Dr. Black, Dr. Boxall and Dr. Duka. Letters expressing sympathy with the movement and regret at being unable to be present were read from several well-known members of the profession. Nothing can be more fitting than such a movement. Though originating abroad and in the native country of Semmelweiss, it appeals to all nations and especially to the medical profession of all nations, which alone can estimate the value of Semmelweiss's simple but fruitful work. He was the pioneer of antiseptic midwifery. Though, in point of fact, antisepticism in surgery was achieved independently of the work of Semmelweiss and on other lines, the presence of Sir Joseph Lister at the meeting shows his appreciation of the labours of that physician. Semmelweiss was the first to demonstrate that the origin of a large proportion of cases of puerperal fever was due to perfectly prevent-

able causes, often attached to the person of the accoucheur. It was in 1847 that Semmelweiss, as assistant to Professor Klein in the Maternity Institution at Vienna, laid down the rule that all persons, previously to the examination of a parturient patient, should wash their hands in a solution of chloride of lime. The mortality fell in a few months from 12 to 3 per cent. We need not here dwell on the significance of such facts. It is painful to think that, like the case of so many great benefactors, his proposals were met with such coldness and resistance and even personal animosity that his mind rapidly gave way and his career closed in 1865 at the early age of forty-seven. There is the more need for a later generation to do him justice and to accord him honour. We sincerely commend this movement to our fellow countrymen and to our readers. This is not an occasion for complaining of the number of demands for testimonials. If life-saving is the supreme achievement of medicine here is one of its finest illustrations. Countrymen of our own for like feats enjoy the fame of all nations. Let us be foremost in acknowledging the merit of a foreigner who has redeemed a branch of the profession from a great stigma and has saved thousands of lives from one of the most pitiful of all deaths.

#### PARENTAL NEGLECT TO NOTIFY, AND ITS CONSEQUENCES.

JESSE WALTON has been fined forty shillings and costs at the Wakefield Police-court for failing to notify an infectious case in his house—that of a little girl, whom the medical officer of health found, after information received, to be comatose from small-pox. She was removed, and died in six hours. Three other children were found to be suffering from the same disease, and the medical officer computed that ten cases had occurred from Walton's carelessness. During the illness he often went to a public-house at the other end of the town, and a relative of the publican took the disease. It is not stated whether the case had been notified by a medical man. The defendant excused himself by saying he understood the case was chicken-pox—a lame excuse under such grave circumstances.

#### A MEDICAL MAN AND HIS FEES.

AT Blackburn County Court lately Dr. Garstang of Blackburn brought an action against John and Martha Padgett, innkeepers of Leyland, to recover £65 for professional attendance, being the balance of an account of £92 10s. incurred between Nov. 2nd and Dec. 8th, 1891. The fee per visit seems large, but Dr. Garstang explained that the journey took him six hours, that he stated what the fee would be after the first visit, and that he could only attend "as a physician." Dr. Berry, physician to the Royal Infirmary, Manchester, spoke of the fees of physicians. His Honour Judge Coventry considered that Dr. Garstang attended "as a physician" and said that, although the charge seemed large, it was a physician's fee, and it was impossible for him to say it was an exorbitant one. He therefore gave a verdict for the amount claimed. It is obvious that when patients summon medical men from a distance they esteem the case one of gravity and ought to be prepared to pay accordingly.

#### PRIVATE FEVER HOSPITALS.

AN interesting point has just arisen which shows that the use of a private dwelling house in a street as a fever hospital can only be prevented by appeal to the High Court of Justice. A house in Marylebone was used for this purpose and application was made to the Local Government Board and to the London County Council asking for their intervention, but both bodies replied that they were not aware of the existence of any statutory enactment which empowered them to prevent the establishment of such an institution and the only remedy

was of the kind mentioned. Without knowing all the circumstances of the case it is impossible for us to express any opinion as to whether there would have been risk from the proposed hospital, but we presume the law as to small-pox hospitals is the same as that for fever hospitals and it is evident in the latter case that considerable danger to the neighbourhood might result. Under all circumstances it is desirable that institutions of this sort should not be conducted by private persons for profit, but should be in the hands of some responsible authority.

#### A. NEW ISLINGTON WORKHOUSE INFIRMARY.

THE question of building a workhouse infirmary for Islington at Tollington-park is a very warm one, and is exciting much opposition. It is uncomfortable to ratepayers to find that the fine infirmary buildings included in the present workhouse, and probably less than twenty years old, are inadequate. Besides, the owners of valuable residential property in Tollington-park are up in arms.

#### FOREIGN EPIDEMICS.

APART from cholera in Persia and in the east of Europe, we learn that plague has broken out in the former country, the province of Khorassan being affected. Yellow fever has also broken out and makes alarming progress in the State and city of Vera Cruz. Hundreds are daily quitting the city in alarm and are travelling to different towns and places in Mexico.

#### THE PREVALENCE OF SMALL-POX.

SMALL-POX, though exhibiting the usual seasonal diminution, does not disappear from some localities as readily as might have been hoped. We still hear of fresh attacks from the vicinity of Dewsbury, from Wakefield, Halifax, Knottingley, Middlesbrough and Handsworth in Yorkshire, and from Enfield, as also from the Dartford rural district, which abuts on the hospital ships. In the metropolis the fresh attacks have within the last few weeks diminished from ten to four, and only seventeen cases were last week under treatment in the floating hospital. The breathing time between the present period and the usual autumnal period of increase should be utilised by authorities in promoting vaccination and revaccination and in providing some permanent means of isolation to be in actual readiness for the reception of any first attacks of the imported disease which may appear.

#### PAPER MONEY AS A CARRIER OF INFECTION.

THE possibility of infection being conveyed to a large number of persons by means of paper money has often been suggested, and an examination of the notes of the Bank of Spain current in Cuba which has recently been published by Drs. Acosta and Rossi in the *Cronica Médico-Quirúrgica de la Habana* shows that this form of currency is indeed liable to contain septic germs. The notes chosen for their experiments were some that had been in use for a good while and were such as represented values of a few pence only. It was estimated that two notes, weighing altogether about fifteen grains, contained more than 19,000 germs of various kinds. Cultures were made in broth, gelatine and agar, and these were injected into the peritoneal cavity of rats and guinea-pigs, most of which died within twenty-four hours, the post-mortem examination showing signs of peritonitis and congestion of the liver and kidneys. The blood of the heart and peritoneum was made use of to inoculate solid media, in which colonies developed so rapidly that it was impossible to determine their precise nature, many different forms being intermingled.

THE following circular has been addressed by Major L. Flower, sanitary engineer to the Lea Conservancy, to the sanitary authorities in the Lea watershed:—"Cholera memorandum: In view of the probable importation of Asiatic cholera into this country, and the necessity of preventing pollution to sources of water-supply, may I ask that—as in 1884, when I made a similar request—you will kindly inform me of any contamination which may come under your notice; and that you will see to abatement of nuisances, such as offensive manure heaps, overflows from cesspools, privies, and such matters in detail, which may contribute to the fouling of the River Lea and the tributary streams thereof."

THE Royal Commission on Vaccination held a meeting at Great George-street on the 20th inst., Lord Herschell in the chair, when Dr. T. Whiteside Hime of Bradford gave evidence at considerable length. Dr. F. Barry, one of the medical inspectors of the Local Government Board, was recalled on the 27th inst. to further explain his special report on the outbreak of small-pox which occurred in Sheffield some years ago. The Commissioners then adjourned until October.

IN order to prevent importation of cholera the Board of Supervision of Scotland has issued instructions to the local authorities of ports that no rags from France, the Black Sea, the Sea of Azof, or from Russia, Roumania, Bulgaria or Turkey, shall be landed in Scotland. Ships having cholera cases on board are to be subjected to quarantine, and arrangements are made for the disposal of the bodies of cholera patients dying on board.

WE regret to have to record the fatal result of an accident to Dr. James Cameron, the medical officer of health for Hendon. Whilst driving in his brougham on Mill-hill the horse took fright and bolted. Dr. Cameron attempted to jump from the vehicle, but in doing so was thrown and fell heavily on his head fracturing his skull. Death resulted before it was possible to convey the unfortunate gentleman to his home.

MEMBERS of the profession who wish to attend the Intercolonial Medical Congress to be held in Sydney from the 26th to the 30th September may obtain information as to concessions in regard to fares &c. from the Peninsular and Oriental and the Orient Companies. Sir Dyce Duckworth, M.D., F.R.C.P., has consented to act as the representative of the Congress in England.

THE Local Government Board has approved the Sanitary Institute as a body whose certificate to the effect that a person has shown himself by examination to be competent for the office of sanitary inspector under the Public Health (London) Act, 1891, shall be sufficient for the purpose of the requirements in Section 108 (d) of that Act.

THE Duchess of Albany, attended by Lady Collins, on Wednesday last distributed, at the Parkes Museum, certificates of proficiency in domestic hygiene to ladies who have attended the classes on that subject at the Sanitary Institute in Margaret-street, W.

AT a meeting of the Middlesex County Council, held on Wednesday last, Mr. W. B. Gordon Hogg, M.D. Edin., was appointed coroner for the western district of the county of Middlesex.

THE medical teaching in Birmingham will from and after Sept. 1st be conducted in the Mason College and not in the Queen's College, which institution will then cease to have any connexion with medical education.

THE  
BRITISH MEDICAL ASSOCIATION.  
MEETING AT NOTTINGHAM.

THE first general meeting after the retirement of the ex-President, Dr. J. R. Thomson, and the installation of his successor, Mr. Joseph White, did not produce any very startling incidents. To be sure the adoption of the report of the Council was not allowed to pass without some protests as to the manner in which the Council assumed it had the voice of the members of the Association, when, as a matter of fact, many of the subjects dealt with had not been discussed in the branches. The reports of the special committees excited but few comments, but that on hypnotism was referred back and strong opinions were expressed against hypnotism, which, it will be seen, was not altogether tabooed by the learned physician who gave the address in medicine the next day. The decision to give more of the funds at the disposal of the Scientific Grants Committee in the form of scholarships is a step in the right direction.

DR. RANSOM, the President of the Section of Medicine, chose for his topic one to which some years ago Sir James Paget drew attention. Although perhaps more suitable for a section of pathology than for one of medicine, it cannot be denied that it is of great interest and possibly of some practical bearing. The reaction of the vegetable organism to external irritants and the processes of repair after injury are paralleled by those which take place in the animal body. There is certainly ample scope here for investigations which may prove to the practitioner a pastime affording him recreation, both bodily and mental, amidst the cares of busy practice.

PROFESSOR VICTOR HORSLEY did not hesitate to confess that the subject of which he is a professor, and which concerned the section over which he was presiding, has practically no existence in the schools. Pathology, he did well to remind us, is very different from mere morbid anatomy, with which it is confounded, and by which it is often replaced in teaching. We should have liked to have heard more reference to Cohnheim and his work, whose researches and teaching represented the essential basis of pathology proper. All will admit with Professor Horsley that pathology should be studied and taught with reference to physiology, that perverted function quite as much as damaged structure ought to be embraced within the ken of the pathologist.

AMONG the special features of the meeting one of the most interesting is an arrangement by Professor Victor Horsley of a series of lantern demonstrations of work that has been done during the year in pathological research. This Section afforded an opportunity to practitioners of seeing collected under one roof, in the course of two or three days, all the best work of the laboratories and of the wards of Great Britain demonstrated by the men actually engaged in the research. The idea was a happy one and was carried out with Mr. Horsley's characteristic vigour and ability. It is probable that the success of this departure will considerably influence the programme and course of the work at the leading pathological societies which has hitherto been too much in the nature of a mere demonstration of post-mortem condition, which, however, is by no means the be-all and the end-all of curative research.

DR. BROOKHOUSE, who presided over the Section of Pharmacology and Therapeutics, was justified in deprecating the unceasing introduction of new remedies with alleged specific effects, many of which are as unknown a year after

their introduction as they were before it. Nor can one admit that the present position of experimental inquiry upon toxins and protective agents in the least justify their introduction as yet into the treatment of disease. Dr. Brookhouse's testimony to the value of tracheal injection of menthol in phthisis was very strong, and he went so far as to aver that his results contrasted favourably with those of the tuberculin treatment. A most interesting discussion took place in the Section of Therapeutics on the subject of the action of medicines on the heart. Dr. Broadbent in an admirable paper discussed the indications for the use and the action of cardiac tonics. On account of the limitations imposed upon him by the nature of the subject he restricted his paper to the use of these drugs, leaving aside what he expressed himself as holding an equally or more important position in the treatment of cardiac disease—namely, rest, graduated exercise, elimination of the waste products and so on. Dr. Brunton laid stress on the extreme value of perfect rest in advanced cases of mitral disease, and advocated this combined with massage, graduated exercise and the use of mercury. He demonstrated Professor Gartner's ergostat as affording a means of exactly limiting the amount of exercise which a particular patient can take. Dr. Clifford Allbutt laid special stress upon the treatment of residual condition left behind by the action of disease. Dr. Oliver of Newcastle and others joined in the most interesting and instructive discussion which followed.

THE importance of adequate clinical instruction in the diseases of children cannot be too strongly or repeatedly enforced. It formed a topic of Dr. Cheadle's address two or three years ago, and it was selected by Dr. Marshall, who presided over the Section of Diseases of Children. The examples he quoted were to the point and the need for really systematic instruction in the hygiene as well as the therapeutics of infancy was thoroughly enforced.

IN the Section of Surgery, Mr. John Croft travelled over the ground of the discussions which were set down on the programme—i.e., the treatment of empyema—hepatic surgery, and the treatment of tuberculous disease of bones and joints. The debate on the Surgery of the Thorax which ensued was shared in by many well-known authorities on the subject.

THE Section of Psychology, which opened with a useful practical address from its President, Mr. Bevan Lewis, upon Asylum Administration, in which the appointment of clinical staffs and nurse-training schools were advocated, began its labours with a highly interesting debate on the Post-influenzal Psychoses, introduced by Dr. Althaus.

ONE of the most interesting exhibitions in connexion with the meeting was the display of the mode of saving life from fire by means of a tubular arrangement consisting of asbestos and sacking, through which descent could be made with absolute safety and with almost incredible speed. The arrangement invented by Mr. Lewis Anidjah was quite a feature of the meeting.

NINETY-FOUR members of the Association and others interested in medical missions sat down to breakfast on Wednesday morning in the Exchange Hall, under the presidency of Dr. Roberts Thomson, ex-President. At the close of the meal Dr. Thomson said that this was the first reunion of the kind that had been held at the annual meeting and Dr. H. Martyn Clark of Umritsur, who has a "parish" of 3,000,000, spoke greatly to the point in favour of medical missions as *the way to the native mind*; for while some might doubt if they had a soul, the body with its troubles made itself evident. The work was real and hard; he had had 60,000 patients and 3000 operations. He was followed by

Dr. Hörnlé, who urged the necessity of sending only the very best men to do medical mission work, as the natives were keen to detect inferiority and the medical missionary had no consultant to fall back upon. They must teach the people to love God by their love to man. Dr. Lock, a civil surgeon, said there was room for both classes of workers in so large a field. The Secretary of the Church Missionary Society added a few words, after which this, the first, and a most profitable and encouraging réunion, broke up.

OUR correspondent, writing on Wednesday, says: "The meeting of to-day is chiefly remarkable for the value of the work done in the Sections and for the very full representation of the younger school of scientific medicine. Among those present were Sir F. Bateman; Sir William Moore; Dr. Bristowe; Dr. Ransom; Dr. Lauder Brunton; Mr. Victor Horsley; Dr. Broadbent; Mr. Lawson Tait of Birmingham; Professor Gairdner of Glasgow, Dr. Maradoc Cameron; Dr. Byrom Bramwell, Edinburgh; Dr. John Macintyre, Glasgow; Professor Cuming, Belfast; Dr. Stokes, Dublin; Professor Semmola, Naples; Professor Baccelli, Rome; Professor Schrötter, Vienna; Dr. Hingston, Montreal; Dr. Stewart and Dr. Roddick, also of Montreal; and representatives and delegates from the whole of Great Britain. The attendance of Members has been up to the present fairly good, and already 800 medical men have visited the town of Nottingham."

NOTTINGHAM Castle was on Wednesday evening the scene of a very brilliant assembly. Fully 1500 guests had accepted the invitation of the Mayor of Nottingham to a conversation. The beautiful castle lends itself admirably to such a function and the hospitality of the Mayor and the Mayoress was much appreciated. The President's garden party at the Arboretum was also much enjoyed.

A NOTEWORTHY step was taken at the Third General Meeting on Thursday, when a resolution was carried to admit duly qualified women as Members of the Association. The decision at the Bath meeting thirteen years ago to the contrary effect may be recalled in this connexion.

#### FIRST GENERAL MEETING: REPORTS OF COMMITTEES.

THE first general meeting of the sixtieth annual meeting of the British Medical Association was held in the Mechanics' Institute at Nottingham on Tuesday, the 26th inst. The attendance of members, as is usual on the opening day of the meeting, was not very large. The retiring President, Dr. ROBERTS THOMSON of Bournemouth, in vacating the chair said that he had to renew the expressions of his warmest gratitude for the confidence which had been reposed in him and for the great honour done him when he was appointed President of the Association. To him it would be the proudest recollection of his life to have occupied that position. He expressed his warmest thanks to all the officers with whom he had been brought in contact for their unflinching kindness and for the courtesy which had been extended to him on all hands. The year which had gone had been an uneventful one and there had been no special or burning questions to consider; nevertheless, it had been a year of very steady progress. The Association had steadily increased in numbers and in usefulness and the amount of scientific work which had been accomplished through its agency was very marked. He had no doubt that the year would mark a distinct advance upon those which had preceded it. In vacating the chair he simply wished the members to accord to his successor the same regard for the authority of the chair which had been accorded to him, and he could have no better wish than that his successor should be able to look back to his period of office with the same pleasure as he had.

The incoming President, Mr. JOSEPH WHITE, senior surgeon to the General Hospital of Nottingham, on taking the chair, said that he thanked the members for the honour and conveyed to them as far as he could his sense of the responsibility which the appointment carried with it. He was quite sure of re-

ceiving at the hands of the members that support which they had always afforded to occupants of the chair, thus lessening as far as they possibly could the labours connected with it.

A vote of thanks to the retiring President was then moved by Dr. HOLMAN and seconded by Dr. SAUNDBY of Birmingham. The retiring President was further elected as Vice-President of the Association for life.

Dr. WITHERS MOORE then moved the adoption of the report of Council and official statement for the year; this was seconded by Sir WILLIAM MOORE, who considered that in it he saw signs of vitality and progress for the Association; he considered the finances were in very good order, the Association had £45,000 to the good, and the managers of the finance department of the Association deserved great thanks.

Dr. RENTOUL (Liverpool) called attention to the balance-sheet and asked that the Council of the Association should give more information to the members. He thought the amount of money spent for editorial expenses (£5000) last year seemed too much. He had asked the general secretary to tell him what amount had been paid for editorial articles, leading articles, correspondence articles, the writing of obituary notices and other special correspondence, but the general secretary in reply had informed him that it was not his province to give such information to members. Now Dr. Rentoul considered that the Association was a limited liability company, limited as it were by guarantee, and he hoped that in future the Council would supply more detailed information in their balance-sheet.

Mr. J. J. CURRAN (Killeagh, County Cork) desired to convey the thanks of the Irish dispensary medical officers to the British Medical Association for the warm interest they had taken on their behalf during the past year. He recapitulated the grievances under which these officers suffered.

Dr. LOVELL DRAGE (Hatfield) called attention to the manner in which subjects of importance to the Association were discussed and illustrated his remarks by reference to the mode in which the views of the Association had been obtained on the Midwives Bill.—Dr. SAUNDBY asked if this was due to the action of the Council or to the action of the Metropolitan Branch of the Association.—Dr. LOVELL DRAGE, continuing, said the Association had no right to use the name of the Association in connexion with legislation on which the views of the members had not been obtained.

Mr. GEORGE BROWN spoke of the way in which the interests of the members were laid aside by the Council of the Association. The Association as a whole had but few opportunities of expressing its opinion in public, or upon the more important questions which were brought before Parliament. What could be of greater importance to medical men than a legislation which would alter the conditions of the practice of midwifery in this country? yet no attempt had been made by the Association to give its members an opportunity of expressing an opinion on a question of such vast importance. It would be in the recollection of many members of the Association that some time ago attempts were made to reform the Medical Acts. On this subject no meeting of the Association could be obtained without the signature of fifty of its members. He thought the Council would be consulting its own dignity and doing justice to the members at large by convening a meeting in London to consider any important question that might arise.

Dr. SAUNDBY (Birmingham) entirely dissented from Mr. Brown's views on the ground that the members of the Council only represented a few of the various branches and could do nothing excepting what these branches asked them to do.

Dr. HUGH WOODS disagreed with the last speaker as to the position of the Council. He thought it was the duty of the Council to respect the rights of individual members, which did not at present exist in the methods adopted by the Association.

Dr. ROBERTS THOMSON suggested that the proper course of procedure would be for these gentlemen to bring their grievances before the Council and ask it to report upon them.

Surgeon-Major INOE observed that out of 14,000 members any question could be settled by the infinitesimally small number of forty-five. This was due to the operation of a by-law passed at the time the Association numbered tens instead of hundreds.

#### REPORT OF THE PARLIAMENTARY BILLS COMMITTEE.

Mr. HART moved the report of this committee. The subject of Parliamentary bills occupied every year part of the time of the Council and in no year had the work been

more onerous and more difficult, yet more promising, than during the last year. The first question he wished to mention was that of the dispensary medical officers in Ireland. The committee there had undertaken work which would require infinite patience, and if too much was expected from its labours disappointment must follow. He had consulted on the subject the Irish Secretary and had found him absolutely ignorant of the facts relating to the conditions under which these medical officers worked, and also opposed, on grounds which could not be tolerated in this country, to the legislation which he had proposed to him for their redress. The opposition of the Irish Secretary in this matter was monstrous and could not be sustained either by Parliament or by the sense of the country. Dealing with the subject of want of representation of views at the meetings of the Council, he said that those from whom the complaint arose had expressed their views at great length fifty times over.—Mr. WICKHAM BARNES, in seconding the adoption of the report, brought forward the case of the late Mr. Walters. The Poor-law Medical Officers' Association were in hopes that forcible representations would be made to the Local Government Board.—Mr. BRADLEY (Drogheda) thanked the Association for the interest they had shown in the Irish dispensary officers and suggested that they should get the Irish Members of Parliament to act on their behalf.—Dr. WARD SMITH considered that the English district medical officers were just as badly off as their Irish brethren and he would like the Association to give them a little attention.—Dr. LOVELL DRAGÉ drew attention to the fact that no mention had been made of the proposed New University Bill.—Mr. HART said that a committee of the Association had been appointed to consider the matter.—The motion was then put by the President and adopted.

#### REPORT OF INEBRIATES' LEGISLATION COMMITTEE.

Dr. NORMAN KERR, in moving the adoption of this report, called attention to the valuable testimony before the departmental committee now sitting and said they wished an amendment in the law in the following respects: (1) compulsion; (2) removal of hindrances to admission of voluntary applicants; (3) provision for the poor; and (4) provision for the treatment of alcoholic, opiate and all other forms of inebriety.—Dr. USHER of Melbourne seconded the adoption of the report and pointed out that any legislation that may be effected or brought about must receive the support of the profession. People naturally sought for some relief from the drink disease and if they could not get it from medical men the danger was present of taking secret cures offered to them. Sir George Dibbs, the premier of New South Wales, in a conversation a few days ago, intimated that he intended bringing in a Bill dealing with the whole question on his return to the colony. The report was adopted.

Mr. BUTLIN proposed the adoption of the report of the Scientific Grants Committee, which was duly seconded and adopted. It was recommended to apply more money to scholarships and less to investigation.

Surgeon-General CORNISH moved and Dr. BARRON seconded the report of the Committee on Scientific Investigation into the Condition of School Children. This committee was considered to be of the highest importance, as upon the integrity of the constitution of the children the future of the nation depended.—Mr. SHUTTLEWORTH said the London School Board had established special classes for backward children.

The report of the committee appointed to investigate the nature and phenomena of hypnotism and its value as a remedy recommended that if used it should be practised only by qualified medical men and under no circumstances should female patients be hypnotised except in the presence of a relative or a person of the same sex. The Committee strongly disapproved of public hypnotic exhibitions. In the course of the discussion Mr. GEORGE BROWN moved that the report be referred back, as there was nothing in hypnotism. Mr. ESDALE said the adoption of hypnotism was perfectly monstrous. Dr. NORMAN KERR thought the report the most striking condemnation of hypnotism that had ever been delivered, as the committee was composed mainly of advocates of hypnotism. The report was eventually referred back.

On the presentation of the report on medical charities Dr. KENTON moved that it be referred back on the ground that twenty millions of people should have medical attendance free. This, however, was not carried. The meeting then adjourned.

#### THE PRESIDENT'S ADDRESS.

At the adjourned general meeting, held in the evening, the President, Mr. JOSEPH WHITE, consulting surgeon to the Nottingham General Hospital, delivered an address on the subject of the development of the Association and of British medicine and surgery since the last meeting of the Association, which was held in Nottingham in the year 1857. In the course of his address he gave an interesting account of the geology of Nottingham and its neighbourhood; the natural facilities it afforded for drainage were described as uncommonly good; the town being built upon an inclined plane rising nearly 200 feet in little more than a mile and sloping directly towards the valley of the Trent. The water-supply, which was under the control of the corporation, was of good quality and abundant.

Having described the physical features of the district and spoken of the improvements being effected in the town, the President then gave an account of the last meeting of the Association at Nottingham thirty-five years ago, noting that at that period the number of members was 2065. Since then the number had grown to 14,000. He touched upon the advances which had been made in British medicine since then. In general medicine the work and writings of such men as Bright and Addison, of Latham and Hope, of Stokes and Graves, of Watson and Gull, and of William Jenner, had done very much to foster and develop that spirit of independent inquiry and accuracy of thought which, in an ever-increasing degree, characterised the progress of curative medicine five-and-thirty years ago; whilst in preventive medicine, which was then coming to the front, two men stood prominently forth as the pioneers in that still greater movement of sanitary advancement which was so soon to follow. These were Edwin Chadwick and John Simon. At the time of the last meeting Mr. Simon had just completed with the greatest distinction his seven years' labours as the first medical officer of health of the City of London, and was about to enter upon his more responsible position of medical adviser to the Privy Council; he then occupied the foremost position not only as a sanitary reformer, but as the most eloquent exponent of the aims and capabilities of preventive medicine in its truly scientific aspect. He and his fellow-labourers in the same field had in a few years so raised the importance of the work of sanitation in the estimation of the profession and the public that it was for the first time in the history of the Association made the subject of one of the special addresses at the last Nottingham meeting in 1857. Mr. White then referred to the advances made in surgery. The teaching of such men as Blizard and Abernethy, the great practical work of Cline, the bold achievements of Sir Astley Cooper, a few years later the still more brilliant operative work of Robert Liston, and later still of James Syme and William Ferguson, had raised surgery to the very foremost rank as an art; whilst the philosophic views of Brodie and of Lawrence, and the philosophic work of Sir James Paget, had done even more to elevate it to that truer position as a science which it was then rapidly achieving. The use of anaesthetics was discovered about this time. Perhaps the greatest achievements of modern surgery had resulted directly or indirectly from the introduction of the so-called antiseptic method, which the profession owed to the genius and labours of Sir Joseph Lister. This was not simple cleanliness in the ordinary acceptation of the term, but that special form of rigorous and refined cleanliness which the pathologist and the chemist alone could appreciate, that prevention and removal of everything of a septic kind which could possibly invade a wound, the attainment of that purely aseptic condition which could only be accomplished by the most scrupulous and watchful care, and no one has done so much to attain that end as Professor Lister. By these two great achievements—by the abolition of pain by anaesthetics and by the greater safety of wound treatment since the introduction of antisepticism—the whole practice of surgery had undergone an amount of development which twenty or thirty years ago could not have been believed possible. This development was very evident in the department of abdominal surgery, including such operations as the removal of the kidney, of the spleen, of the uterus and its appendages, of portions of intestine, of bladder tumours, and of various kinds of tumours within the abdomen and operations upon the liver and upon the gall-bladder. The surgical treatment of diseases of the brain afforded other proofs of development. The discoveries of Hitzig and Fritsch

during the Franco-German War in 1870 and subsequently of Ferrier—that when certain limited areas of the brain surface were stimulated by galvanism this stimulation was followed by contraction of definite groups of muscles in different parts of the body—became the basis of further researches and investigations, which had been carefully pursued. Year by year the knowledge of the localisation of brain function had become further extended and more and more precise until it had resulted in those great achievements of brain surgery which, at the hands of Horsley and Macewen, and since then of many others, had been attended with such marked success. Advancement was also manifest in the other fields of medical science, in the application of physical science to the investigation of disease, and in the more rational application of the laws of sanitary science to the promotion of the public health. The President referred to the work of Dr. Seaton and Sir George Buchanan as evidence of the great advances of sanitation in England. Regarding preventable diseases, he remarked that Sir John Simon was not content with inspection only or with the application of such knowledge as was then possessed. He felt and he pressed upon the Government the need of new knowledge—of knowledge only to be obtained by extensive laboratory investigations of the most careful and subtle kind and carried out by special observers of the highest scientific attainments; and it is to those investigations, made under the auspices of the Privy Council and conducted with the greatest care, that the profession were now so much indebted for many of the recent great advances in preventive medicine. In bacteriology also much important progress had been made. At no other time had a greater number of active and vigorous minds been engaged in original research, and never before had a more promising light dawned upon the future of medicine.

Professor HINGSTON of Montreal, in moving a vote of thanks to the President for his address, said that the name of Joseph White was synonymous with all that was honourable and dignified in the profession. His address was full of good sense. It was a pleasant duty to him to move the best thanks of the Association to Mr. Joseph White for his very interesting address.

Sir FREDERICK BATEMAN seconded, and the resolution was unanimously carried.

#### THE ANÆSTHETIC COMMITTEE.

Professor VICTOR HORSLEY (London) moved the adoption of the statement as to the work in progress under the Committee on Anæsthetics. He pointed out that it was rather a statement as to the work to be done and the hints that had already been received. It was intended to work clinically and he hoped experimentally. The clinical work had been organised and arranged according to the schedule which they held in their hands, and the experimental work, he hoped, would assist them in the discovery of impurities in anæsthetic agents.

Mr. CROFT said that, as an old hospital surgeon who had seen anæsthetics administered in nearly 14,000 instances, he thought he might claim to have some reason for supporting the resolution.

#### PAYMENT OF PARLIAMENTARY BILLS COMMITTEE.

Surgeon-Major INCE moved at great length a resolution condemning the principle of payment of members of the Parliamentary Bills Committee.

Dr. RENTOUL moved as an amendment: "That, while not recommending the payment of members of committee for services or time given, from henceforth each member attending the Parliamentary Bills Committee be paid first-class return fare out of the funds of the Association, which was following the course of payment of members of the Council." After prolonged and turbulent manifestations the meeting negatived both the amendment and the substantive motion.

The meeting then adjourned.

#### THE SECOND GENERAL MEETING.

The Association met in the Mechanics' Large Hall on Wednesday afternoon to hear the address in medicine delivered by Dr. Cuming of Belfast, which we publish in another column.

#### PLACE OF NEXT ANNUAL MEETING.

Dr. WITHERS MOORE, the President of the Council, announced that the next annual meeting would be held at Newcastle and Dr. Philipson was elected President for the coming year.

#### THE ADDRESS IN MEDICINE.

The address was listened to with manifest pleasure by a very large audience and Professor GAIRDNER of Glasgow moved a vote of thanks to Professor Cuming. In doing so he thought that the elementary sciences had held their own ground in medicine and no doubt would continue to do so. Sir CLIFFORD ALBUTT seconded the resolution. This concluded the business of the meeting.

#### THE SECTIONS. MEDICINE.

The President, Dr. RANSOM, Consulting Physician to the General Hospital, Nottingham, delivered an address at the opening of the Section of Medicine on the subject of "Some Diseases of Plants compared with those of Man." He thought nothing could be foreign to the student of medicine which touched upon perturbations in the organic world, and he devoted his address mainly to plant diseases which corresponded to the inflammatory processes of living organisms or the reaction of living cells to irritation. All such reactions in plants form "galls" or witch-knots. A gall he defined as a local hyperplasia or overgrowth of tissue, differing from local hypertrophy in diverging from the normal tissue or organ with which it is related. The irritants which produced these were sometimes mechanical or physical agents, inorganic substances, or arose from living organisms. Among the acari the phytopti or gall-mites were the best known. From whatever cause the disease is produced there is such a definite relation of the process to the irritant that the evolution of the gall is mainly directed by it and the product is therefore specific. Some of the parent insects, while depositing their eggs, wound and kill portions of the plant where the egg rests and the reaction occurs in the nearest living cells. Some of them do not wound the tissue where the ovum rests, while neighbouring parts are wounded. Although it was possible that the irritant is sometimes mechanical or physical, it more probably always is some organic liquid chemical substance, not very diffusible, produced in small quantities either continuously or at short intervals during a small part of the life and development of the parasite, and having a different composition in each species.

The lecturer exhibited some selected examples, some specimens, photographs and drawings to illustrate his subject. He showed that the common oak apple was due to the deposition of ova in a bud by the unisexual form *Biorhiza aptera* derived from a root gall; and it yielded the bisexual form *Teras terminalis*, which lays its eggs in the young roots and produces the root galls. The mode in which this change was brought about was described in detail. The common currant gall of the oak, as he showed, follows the deposit of an egg in a bud early in spring by the unisexual form *Neuroterus lenticularis*, itself hatched from the red spangle, and it yields in June the bisexual form *Spathogaster baccharum*.

He further demonstrated that the common red spangle was due to the deposition of an egg by the *Spathogaster baccharum* in a wound between the surfaces of the young oak leaf in June; and it yields the *Neuroterus lenticularis* in the following March. Parenchyma, fibro-vascular bundles and epidermis were all wounded, and a portion of the latter was killed at a little distance from the puncture on the lower surface of the lamina. The plant suffers very little injury. Often two or more species of spangles are met with at the same time on the same leaf, showing in the strongest manner the prepotent influence of the irritant in determining the character of the reaction. The common nut gall was caused by *Cynips kollari*, a parthenogenetic insect, which makes a wound, but leaves its egg upon an intact and very young bud. The wound heals and the young gall springs from the unwounded cells upon which the egg rests; soon it encloses the embryo by an embryonic meristome which is free from chlorophyll, and then develops into a complex structure which contains chlorophyll and is extremely heterologous. The artichoke gall illustrates a somewhat different mode of extension of the influence of the irritant beyond the true gall. The bud axis, which at its apex bears the gall, carries at its base a large number of modified scales and these serve as a protection to the true gall before it is thrown off by a sort of dehiscence. In this case the protecting scales and the basal part of the bud axis are not, as in the previous example, mere hypertrophies and they soon die and are cast off.

Having dealt with the willow galls, Dr. Ransom next

referred to "witch-knots" and allied formations. All the cases went, he thought, to show that the irritant was an organic chemical substance and to support the view that the process of irritation is some gentle persisting disturbance of the metabolism of the living cells, during which cell multiplication was inhibited where it first acted, but stimulated just outside that part. He did not know of any theory of inflammation comprehensive enough to include plants. The widest was that put forward by Metschnikoff, in his "Leçons sur la Pathologie comparée de l'Inflammation," but even that did not include plants. The lecturer ventured to suggest one which he thought sufficiently comprehensive, and which might be stated in the following terms: "In virtue of those necessary and inherent faculties by which all organisms repair damage, living cells react in response to true irritations by a proliferation with modification directed by the irritant, and not beneficial to the organisms in which the process occurs." This definition implied that all inflammations were specific, even if the phenomena ascertained were not sufficient to prove them to be so.

#### SURGERY.

In taking the chair in the Surgical Section, the President, Mr. JOHN CROFT, limited his preliminary remarks to a brief prologue on the subjects selected for discussion in this Section. He said: "Imagine that the surgical treatment of pleural effusions, whether serous or puriform, has been so far advanced during the last ten or twelve years that certain formulæ may now be admitted:—(1) That early evacuation is the best principle to act upon; (2) that the exclusion of air where practicable and the observance of aseptic or antiseptic technique should be rigidly observed; (3) that complete and perfect drainage of the cavity under treatment is essential, including counter-openings and large openings into the pleura or other pushing cavities; (4) that large cavities require adequately large openings; (5) that ribs and periosteum, intercostal vessels and nerves may be largely excised with advantage immediate and prospective, so long as ordinary precautions are observed; (6) that lack of early and adequate operations are important causes, though not the exclusive causes, of delay in the closing of cavities; (7) that lung abscesses and gangrenes and bronchiectatic cavities, with certain obvious exceptions, are amenable to surgical exploration and treatment; (8) that hydatid cysts in the lung or pleura may be successfully extracted or in other ways cured by thoracotomy. It will not be safe, at the present stage of our experience, to extend the formulæ. They reach as far as amenable cases go, but there remain to be mentioned those instances of disease and difficulty which are found to baffle the physician, whose province it is to define the disease and its locality, and the surgeon, whose province it is to bring surgery to assist medicine. 1. Difficulty of diagnosis, which may cause the physician to delay surgical assistance; for instance, the defining remote, small, pleural effusions and lung abscesses. 2. Procrastination for other reasons. For the latter one can offer no excuse, but for the former difficulty a surgeon can offer this amount of assistance—namely, repetition of exploratory incisions and punctures. 3. When a large cavity is placed under the scapula. 4. When an enormous pleural cavity is bounded on one side by a collapsed, movable, swinging, dangling lung, and on the other side by rigid bony wall. This is a most formidable difficulty to overcome, and particularly when there is little or no disposition to the formation of granulation or cicatricial tissue. Sponge-grafting has failed. Abstraction from the wall of the chest of a great portion of its bony rigidity does not necessarily succeed. This is a condition of things which we may hope that this meeting will enlighten. I would ask in this connexion this question: Would the removal of the useless swinging lung, at or near its root, be a safe and useful measure? I am disposed to think that its presence is an obstacle to the cessation of discharge from the pleura, and that its removal would be a step half way to cure. I am supposing that the lung is useless as a respiratory organ and that adequate measures for its fixation have failed of their purpose." The loss of such a spoiled organ should prove to be a gain." In speaking of the surgery of the liver and gall-bladder, Mr. Croft said: "Gentlemen, brilliant as are results obtained in the surgery of the liver and gall-bladder by Messrs. Lawson Tait, Mayo Robson, Knowsley Thornton, Jordan Lloyd, Pearce Gould, and others in this country, there remain difficulties yet to be overcome and questions yet to be settled. I here allude to (1) the treatment of hydatid cysts of the liver which

have already opened or which threaten to open into the chest; (2) the question of early operation in cases of cholelithiasis; (3) the desirability of suturing the incision into the gall-bladder and of then closing the abdominal incision and cavity; (4) when the gall-stone is impacted in the duct and cannot be reached through the gall-bladder, should the duct be incised and the incision sutured, the omentum being employed to strengthen the fastening? (5) the question of whether ligature of the cystic duct without cholecystectomy is to be preferred to other operations; and (6) the cases in which cholecystectomy is to be preferred to less radical proceedings. Lastly, the interesting topic of cholecystenterostomy will arise—when it is to be resorted to and the best mode of carrying out the operation."

The President also referred to the subject of the surgical treatment of tuberculous disease, the essential pathology of which is the same whether the neoplasm is in bones or joints of limited mobility—as in the spine—or in the bones or joints of the utmost mobility in the extremities.

#### PUBLIC MEDICINE.

In opening the proceedings of this Section Sir B. W. FOSTER, who presided, after some preliminary remarks went on to say that public medicine really meant the relation of certain members of our profession to the well-being of the community at large, founded on a scientific knowledge of the causes, distribution, methods of infection by disease and the mode of preserving the public health. There was no function so important to a medical man, even although it involved enormous responsibility, and if well performed it would meet with speedy recognition at the hands of the citizens among whom he laboured. Throughout the country the position of medical officers of health was obtaining this recognition both from local authorities and from the State. Recent legislation in connexion with the Local Government Board had been specially associated with developing the functions of these officers. In England they were as yet a little behind Scotland in the matter of sanitary legislation, and the good effects of the English legislation on the subject had been marred by defective clauses in connexion with the health government of large county areas. In Scotland they had better materials to work upon, and the late House of Commons had instituted certain clauses of the Local Government Act to Scotland which had placed the medical supervision of the county areas of that part of the kingdom under a very good and increasingly effective system of sanitary administration. In factory legislation for manufacturing districts and on all sides this branch of the profession was obtaining as it were a larger share in the management and the control of the complex civilisation in which we live. This he looked upon as very satisfactory to the members of the profession. One of the objections which reached him as a public man was that the increase of power would lead to a kind of medical tyranny. We had suffered in the past from clerical tyranny and was it not likely that we might suffer in the future from medical? He did not anticipate such an event. Supervision could not justly or appropriately be called tyranny, because the supervision would be made by local authorities who were elected by the people, and it would be under their control that the functions of the officer and the exercises for the attainment of a common object and not for the sake of his particular opinions. The very intimate relations of the medical man to the daily life of every individual in the land had been satisfactorily established. The medical profession had always maintained such a high standard of honour in connexion with these varied duties that it afforded no slight guarantee that the duties of medical officers would be performed without offending or prejudicing the public. Another argument against thus increasing the powers of health officers was that legislation tended more and more to interfere with the liberty of the subject. It was said that the Notification of Diseases Act interfered with that liberty, but it was with the liberty of spreading infectious disease. Individual liberty in a civilisation like ours, becoming every day more complex, must be interfered with when it becomes a detriment to the whole community. Legislation which tends to prevent such a danger was most beneficial. Effective legislation would bring about less ravage and destruction from many diseases which have for so long run riot among the public. For instance, effective isolation might stamp out infectious diseases like scarlet fever, measles and small-pox, under direct supervision and medical action, or, at any rate, might be reduced to a

comparatively small amount. On these grounds legislation in the future would have to proceed very much on the same lines as it has done in the past. The duties of the medical officers would become of greater and greater value to the public and be still more appreciated by the State, and the office of Public Health would become one of the most distinguished to which a medical man could aspire. In conclusion he hoped that the Local Government Board, the local sanitary authorities and the medical officers of health would be brought into closer relations and that a larger number of inspectors would be appointed to give advice to local officers—to act, in fact, as consultants sent from the central authority to aid and advise the local men. This would give them the highest scientific opinion without having too much power vested in the central authority.

Dr. F. F. BOND read a paper on Small-pox in Brighouse, Yorks. In the district affected there were three separate administrations. The origin of the epidemic was traced to cases which were not recognised; several separate centres had been infected before recognition. Vaccination and revaccination were carried on in infected houses and the effect of those operations on persons already infected with the disease was described.

Dr. JOHN W. MASON (Medical Officer of Health, Town and Port of Hull) also read a paper on Methods of Dealing with Town Refuse in the Midst of Populous Districts. He said that the subject was of paramount importance to the well-being of a community; the more frequently and efficiently it was collected and disposed of the better was the public health. The reports of the Health of Towns Commission and the Sewage of Towns Commission and the reports of the medical officers of the Privy Council and Local Government Board gave ample evidence on this head. With the natural growth of large towns the question of the collection and disposal of town refuse required the serious consideration of those responsible for the public health and welfare of the population. From the geographical position of some towns the water-carriage system commended itself, as being not only the most efficient from a public-health point of view, but as that which was least injurious; where there existed no natural outfall, from the low-lying position of the town or tidal influences, the introduction of auxiliary steam power effected that which had otherwise not been provided for by natural gravitation. In other towns irrigation or precipitation had to be resorted to in order to obviate or minimise the nuisance. Dr. Mason suggested that to deal effectually with the refuse of large and populous districts the area should be divided for purposes of sanitary administration into districts and that destructors should be erected, having, where procurable, railway and wharfage accommodation, to which all excreta and town refuse collected (including that from slaughter-houses and all condemned food) should be taken, and that of a manurial value disposed of; failing which, this matter, together with trade refuse, should be cremated.

#### PSYCHOLOGY.

The President, Mr. BEVAN LEWIS, Medical Superintendent of the West Riding Asylum, Wakefield, delivered an address at the opening of this Section on "Some Desirable Extensions of Asylum Administration." He proposed to deal with those eminently practical aspects of insanity and its treatment which embrace the functions of the medical staff, and especially of the asylum pathologist, their mutual relationships and common interests; and, in the next place, the organisation of a nursing staff, the possibility of extending their functions, of augmenting their utility, and of elevating their general *morale* and culture. The pathologist of these institutions was at one time looked upon as a 'sport' and had to give way to what was called the practical man, familiar with the condition of the crops, able to descant to a nicety on the probable yield of the dairy and familiar with the finances of the institution, but who would be involved if asked the differential diagnosis between chronic alcoholism and general paralysis, and to whom the tracts of the spinal cord and cerebrum would be *terra incognita*. He had heard it stated over and over again that a superintendent could foster and encourage pathological research in his institution without taking to himself an active interest in the work; this was open to the gravest doubts. Much of course in this case depended upon the community or sympathy existing between the other members of the assistant staff; but still, to suggest that he could wisely

supervise, guide and intervene where such guidance and advice were called for without a due appreciation of what the pathologist's work involved appeared as serious a fallacy as that of regarding him as an efficient supervisor in other departments wherein his knowledge may be faulty and his experience meagre. These young men required guidance, encouragement and advice from their superintendent, and naturally rebelled against the false position of being left to their work, to follow altogether their own bent and inclination. These considerations indicated the necessity that the head of a large institution should take a more real and personal interest in the work of his pathologist; and unless this want was more and more realised the results accruing from the labours of this official would not be equivalent to our expectations. The genuine man was not necessarily one of brilliant parts, nor one averse to undertaking wearisome investigation, but the quiet, unobtrusive, assiduous plodder who did not disdain a preliminary drilling of some years in the most arduous duties of the laboratory. Dr. Yellowlees had years since at Liverpool urged the necessity for some central laboratory to deal with asylum material, but at the time he (the President) was only too painfully conscious of the labour and magnitude of the work so involved to regard it as at all practicable.

Mr. BEVAN LEWIS then emphasised the establishment of a clinical staff of assistants in all large asylums and of an out-patients' department. It would be valuable to an assistant staff, and go far to break down the partition wall of sectarianism, so calculated to congeal their best faculties. He also advocated the promotion of nursing and ambulance lectures and outdoor private nursing. At present the only resource for the neighbourhood was to fall back upon the very limited number of superannuated officials residing there and who were fit persons for the service. The system adopted in the West Riding was as follows. A certain number of skilled nurses are chosen as a private nursing staff, temporarily resigning their post upon the regular staff, their names being struck off the books and their wages and incidental expenses being paid out of the private fund accruing from their earnings. Meanwhile the vacancies so created are filled up on the regular staff by probationers, who offer their services, unpaid, for instruction in nursing, and who succeed to the vacancies occurring from time to time from resignations and other causes. In conclusion, the President thought the scheme might be more generally applied.

Dr. RAYNER thought the best thanks of the meeting should be given for the address and that the nurses' scheme should be widely adopted.

Dr. LINDSAY also thought the meeting was indebted to Mr. Lewis for his scientific address and spoke in warm appreciation of the nurses' scheme and the improvements in clinical and pathological teaching. He said that if the President's suggestions were acted upon a distinct advance would be made in asylum management. He congratulated Mr. Lewis on the liberal spirit which influenced the West Riding Committee.

Dr. ALTHAUS opened a discussion on Psychoses after Influenza. He said that no true post-grippal psychoses had been described previously to 1890, for, with the exception of a case mentioned by Sir Crichton Browne, all other cases previously described have been those of initial delirium. He proceeded to consider these affections in connexion with other and better known post-febrile insanities, and exhibited a table showing the principal points in those psychoses which are apt to come on after rheumatic fever, pneumonia, ague, the acute exanthemata, erysipelas, cholera, and influenza—viz., the number of well-observed cases of these several affections, the influence of sex, age, and general and special predisposition, their duration, and the eventual result. He submitted the following points:—1. Relative frequency: He had found that they were not only absolutely, but also relatively to the number of cases of the parent affection, more frequent than the latter; and that the only acute disease which could at all compare with influenza in this respect was typhoid fever. 2. Sex and age: It was shown that the male sex was more liable than the female, and that most cases occurred between twenty-one and fifty years of age. 3. Predisposition: This was found to have been present in 72 per cent. of the cases, but Dr. Althaus drew attention to the tendency prevailing in medical writings to exaggerate that influence from sheer force of habit. Alcoholism was present in 11 per cent. 4. Relative importance of the fever and the special toxine of influenza. He considered the toxine the more important agent of the two.

more especially in the production of melancholia and general paralysis, the fever being neither sufficiently severe nor protracted to explain the symptoms observed. The fever was, however, of influence in the post-grippal delirium of collapse. 5. Duration: 12 per cent. recovered in a week, 32 within a month, and 56 lasted beyond a month. 6. Proportion of cured, uncured and fatal cases: 7.6 per cent. died, 56.6 recovered and 35.8 remained uncured. 7. Relationship between the severity of the feverish attack and the subsequent appearance of psychoses: The latter were most apt to appear after comparatively slight attacks—viz., 55.2, then followed severe attacks with 27.6, and last came those of medium severity with 17.2. 8. The length of time that may elapse between the feverish attack and the outbreak of the psychosis varied according to the form of the psychosis, the delirium of inanition following close upon a crisis, while melancholia supervened between a few days and weeks after, and general paralysis of the insane later still—viz., up to six months after the attack. 9. Is there any special form of psychosis—a true grippal insanity—caused by influenza which does not occur after other fevers? Four different groups of psychoses were described, none of which were absolutely peculiar to grip, but they differed from other post-febrile insanities by presenting a much greater variety in their clinical features, those most nearly allied to them being the post-typhoid psychoses. 10. How does influenza affect those previously insane? Various epidemics in asylums were referred to showing that insanity constituted in no way a protection against grip, and that in many lunatics the attack of influenza left their mental condition unchanged, while in others the latter was either improved or aggravated. Dr. Althaus thought that such various results might be owing to different vascular conditions. 11. The treatment was successively considered of melancholia, the delirium of inanition, special forms of insanity grafted on pre-existing neuroses or psychoses, and of general paralysis of the insane.

Mr. LEWIS, in inviting discussion, asked the views of others as to the line of demarcation which existed between the effects of influenza upon the sane and the insane in asylums. He had found in his asylum no alteration in mental symptoms after attacks. But outside he had seen profound psychosis very frequently. Why should not it occur inside the asylum?

Sir F. BATEMAN (Norwich) said he knew cases of obscure diseases occur through poisoning of the nerve cells by the special toxine, the ordinary symptoms of influenza being absent.

Dr. RAYNER (London) thought there was an increase in insanity from this cause.

Dr. GOODALL (West Riding) said that every form of psychosis may follow, including paranoia and general paralysis. He alluded to a chronic case of paranoia cured by influenza.

Dr. LINDSAY (Derby) said he had 130 cases, seven-eighths of the attendants having been attacked, but only one-seventh of the patients.

Dr. URQUHART (Porth) thought it would be a pity if this discussion stopped here without making a collective investigation of asylum experience, and mentioned a case in which simple mania had occurred without any known predisposition. Most of the cases would be found to be chiefly due to predisposing causes.

Dr. JULIUS MICKLE alluded to several cases of mental disease directly due to influenza. He criticised the admission into this group of those cases which occurred six months after convalescence, and said that very careful study of this history should be made before including these cases. He spoke of cases in which further inquiry disclosed other causes, such as alcohol.

Dr. BATEY TUKE said the paper was a very important one. He agreed with Dr. Mickle that the utmost care should be taken to ascertain all the causes, and said that if possible differentiation should be made between those due to toxine and to mere exhaustion. He related two cases in which conscious delusions were present.

Dr. CORNER said that at Bethlem 50 per cent. were melancholic, 50 per cent. excited. He added that a distinct class existed in which confusion was a marked feature.

Mr. RICHARDS (late of Hanwell) said it is now fashionable to have influenza, the reliability of the history is often doubtful, and at Hanwell no alteration in symptoms after influenza occurred.

Dr. RICHARDSON (Isle of Man) said that under the action

of influenza unruly patients became quite orderly. He thought one case was actually benefited by the disease.

Dr. ALTHAUS replied. He stated that the utmost care was taken about including cases occurring six months or less after the attack, and then only when some symptoms had occurred throughout the interval.

At the conclusion of the discussion Dr. URQUHART proposed and Dr. RAYNER seconded that this Section should recommend the Council to institute a special investigation into the effects of influenza in asylums.

Mr. St. JOHN BULLEN read a paper on Variations in Type of General Paralysis. He said that opinions were very varied on this subject. He had abstracted 250 cases from Wakefield Asylum; all were fatal and all were males. Sixty-four per cent. of his cases showed optimism, while only a small percentage were melancholic; 28 per cent. had dementia, primary and progressive, and this, he thought, appeared to be on the increase in certain districts. He said that several authorities did not think there was any variation in type among the upper class of patients. The average duration at Wakefield was two years and a half. Investigations showed that post-mortem adhesions were just as frequent now as previously, or 62 per cent.

Dr. JULES MOREL (Belgium) observed that general paralysis seemed to be increasing in Belgium.

Dr. MICKLE said his records were different. It was, however, very difficult to estimate the duration of the disease. With regard to change of type, he thought the percentages depended upon the failure to recognise clinical varieties in the past. He admitted that a change of type was possible on account of changes in the race due to evolution and civilisation, and this was towards depression at the expense of optimism. He said that the increase of dementia as well as the increase of melancholia was partly due to a failure to observe and record those varieties some years ago, the mind of the observer being influenced by previous ideas of the nature of the disease.

Mr. BULLEN, in reply, said that Dr. Mickle's remarks had gone far to show that a variation in the type of general paralysis was not so well established as many had supposed.

Dr. MOREL read a paper on the Psychological Examination of Prisoners, in which he urged that criminals becoming lunatic should be treated in separate institutions attached to the prisons and should be attended by specially trained attendants. He suggested that weak-minded prisoners should be preserved from association with the lowest class of people, and contended that there ought to be a medico-psychological service in all prisons.

Dr. URQUHART said that Belgians were foremost in investigating this subject, and that Dr. Morel had been appointed for this purpose and his experience had been great. In Scotland steps had been taken towards giving partial punishment to persons partly lunatic.

Mr. LEWIS thought there is an increasing demand for inquiry into the mental condition of criminals.

#### PATHOLOGY.

The President of this Section, Mr. VICTOR HORSLEY, in opening the proceedings made a few preliminary observations on the treatment of pathology by those who have to examine in it and teach it in this country at the present time. He said: "However absurd the statement may appear to some, I venture to assert that pathology, as such, is almost unknown among us. The fact is, that what is commonly spoken of as 'pathology,' taught as 'pathology,' and made the subject of examinations in 'pathology,' is nothing of the sort—it is not pathology, it is morbid anatomy. Suppose a student had paid to be instructed in physiology, and suppose that all his teacher did was, first, to describe the coarse or naked-eye structure of the healthy body, next its minute or microscopical structure, and, finally, to make some crude guesses as to how the various organs worked, should we not say that that student had been defrauded? Yet is not this picture a fair representation of what is usually done with pathology in this country? We have in London a society whose function, as defined in its title, is to promote the study of pathology, but, unfortunately, it has hitherto been only an emporium of morbid anatomy. Thus, even when during the last two years as many as 320 papers were communicated to the Pathological Society, not 10, and in 1890 not a single one, dealt primarily with the pathology of any disease. I shall not be misunderstood or thought to depreciate morbid ana-

tomy *per se*, but I regret that in the representative work of the Pathological Society this study should be allowed to usurp the place of pathology. The pathologist should be the student of disordered function as well as disarranged structure; morbid anatomy is therefore but one side of his work, pathology is the other. As, however, so far as I am informed, there are only three places in England where pathology is taught, the paucity of true pathological research among us cannot be regarded as a matter of surprise. It does not seem to be generally appreciated that what is required at the present day is the accurate determination of the aberrations of normal function, and, seeing what strides normal physiology as a science has made, no difficulty attends the pathologist in this new and fertile field. To take a concrete example, the vast range of diseases of the respiratory functions. What a mass of facts has been accumulated in elucidation of the various changes in the structure of the lungs produced by pneumonia, phthisis, &c.; but how many workers have been found to investigate the degree and effect of the loss of the respiratory function, of the disorder of the normal oxygen and carbonic acid ratios! Yet this is what kills, this is the whole work of the disease, and this is what must be solved before the treatment of such diseases can be worthy of mention other than as mere empirical palliation. This, the pathology of the diseases of the respiratory organs, is a subject before which the facts of morbid anatomy will seem more and more restricted as the intricacy and breadth of the problems it is often supposed to solve are properly considered and appreciated. To take another example—a much smaller one, but involving most fundamental considerations—I mean the condition spoken of as œdema or dropsy. What is more common at the present day than to hear this condition gravely ascribed to alterations in the blood pressure alone, and chiefly to venous stagnation? Even in this very year, in a great discussion on the point, and one which appeared to many to be fruitful in little but surmises, these notions were freely promulgated and confidently relied upon. Yet they have for more than twenty years been absolutely contradicted by experimental pathologists, and shown to be untenable. To what, then, are we to ascribe this surprising indifference to pathology? I have not the slightest hesitation in saying that it is due to want of familiarity with modern progress in physiological and chemical research. Fortunately, laboratories are springing up now on all sides, original investigations are being pushed forward, light and knowledge widely diffused. The reproach that we have been dead-house students rather than true pathologists will therefore soon be wiped away."

#### DISEASES OF CHILDREN.

Dr. MARSHALL, the President of this Section and Surgeon to the Children's Hospital, Nottingham, delivered an address on the need for systematic instruction in diseases of children. He said: "Children's work is still lightly regarded by the profession and the importance of the subject is not valued as it ought to be. Dr. Latham very pertinently remarked that 'any class of diseases not falling within the range of professional education and having no ready opportunities provided for its study, has a good chance of never being studied at all.' Nevertheless, three-fourths of our medical students will be actively engaged in the practice of their profession with the class of work which, according to some authorities, virtually occupies no place in the curriculum. The medical tyro, when he has to face these cases, readily yields himself up, and feebly remarks, as was said to me not long since, that 'of course, women know more about babies than we do.' With such a state of mind it can not be wondered at that children's diseases appear to some to be included in 'teething and worms,' water on the brain, and, last but not least in its frequency, consumption of the bowels. It is still less surprising that congenital hernia nearly always appears with a phimosus untreated, and, as once happened in a case sent to me, a large empyema on the right side, with the liver pushed downwards, to be diagnosed as a case of disease of the liver. Again, I received a case with a request to advise the best form of spinal jacket for a lateral twist in the dorsal region. One-half the chest was filled with fluid. On pointing this out by letter to the medical man by whom the patient was sent, I received a reply to the effect that he was perfectly aware of the effusion, but he hoped to produce absorption by the pressure of a jacket. This man deserved to succeed, but his shrewdness might be better applied.

I think we all here are agreed that the first step towards studying satisfactorily children's ailments is the acquisition of the necessary tact. The proper way of managing children is not acquired in the class-room, but can only come to those who seek to obtain it by constant association with sick children. This could not be done in an out-patient department. I have never been able to understand why it appears to be considered *infra dig.* to be acquainted with every detail of baby life. I do not think that I have suffered much because I have made it my business to be able to talk about most things connected with the diet, dressing and housing of a bairn, neither can I believe that I am justified in assessing the value of the life of my patient by his or her length and weight. A knowledge of these things, which would be included under the heading of 'Nursery Hygiene,' should be learnt as a student. To a man entering upon his career in general practice this knowledge would be of great value. If this had been so, would that wretched invention a baby's binder have been so long in vogue? Would the hand-rearing of children have so long continued to be a mere shuffling process of patent foods in the hope that one may prove to be trumps? Should we have had the persistent use of sleeping cordials with which the baby:

When crammed with food and tightened every limb,  
Is dosed to give him comfort?

It were well to add the concluding lines of the above, although the nurse is referred to and not the doctor:—

Soon may she spare her cordial; not a doubt  
Remains, but quickly he will rest without.

Crabbe in no way overstates the case, as everyone knows who sees much of children's work, and our profession must morally accept an adverse verdict."

#### THERAPEUTICS.

In the Section of Pharmacology and Therapeutics the President, Dr. BROOKHOUSE, Senior Physician to the General Hospital, Nottingham, delivered an address upon some points in pharmacology and modern therapeutics. Medicine, he said, using the term in its largest and broadest significance, was at once an art and a science based upon observation, experiment and practice. Science, he added, had given much, if in some instances it may have led to error; but in every field of experimental work error would be discovered, and truth was only revealed by long and patient watching. Most of our present remedies were the outcome of experiments made with natural products, animal, vegetable or mineral, or with compounds which the chemist has put at our disposal. For the chemist has not only separated the active principles from vegetable and animal substances, but he has produced hundreds of new compounds, both organic and inorganic, some of which have been found of the greatest value as curative agents—for example, bromide of potassium, chloroform and nitrite of amyl. It has long been known, however, that the action of even the simpler of these substances is the resultant of the properties of the atoms or groups of atoms of which they are composed; that, for example, the atom of bromide and the atom of potassium in bromide of potassium has each a special physiological influence on certain tissues and organs. The physiological action of these atoms can usually be traced in the various combinations which they are capable of forming. At least a score of new substances have been introduced during the past twelve months for the purpose of fulfilling some definite therapeutic want, and though doubtless many, probably the majority, would not be of practical service, still there was evidence that some might prove to be very useful medicinal agents, and there was great hope that with increasing knowledge new compounds would be formed, which would be of incalculable value in the treatment of disease.

Alluding to the use of the lower forms of life which are connected with disease, and respecting recent researches on toxins as protective agents, Dr. Brookhouse said: "It is quite possible that some methods of treatment, founded on the knowledge which has been gained by the influence of micro-organisms and toxins, may not prove capable of practical application; if, however, this be the case, certain facts as to this influence are proved, and we have good grounds for hoping that further experiments made on the use of micro-organisms and their products will before long put in our hands new therapeutic agencies for the cure of infectious diseases in man. Doubtless in this kind of experimental work difficulties may arise from the varying behaviour of

different animals under one and the same toxine, and that in man the results may differ from those seen in the lower animals. For this we are not unprepared, because the varying action of ordinary drugs in man and the animals and between families, such as the herbivora and carnivora, have long been known. But notwithstanding these differences, experimentation upon the lower animals has proved of the greatest value to man; and the outcry against this method and the prejudice against it which still largely exist are not creditable to the intelligence and candour of its opponents; whilst the progress, in this country at least, of scientific research has been materially hindered by this opposition and the advantages which would undoubtedly have resulted to man have been thus diminished and retarded."

Again, the conditions of physical strain and mental tension, due in great part to the conditions of social life, were provocative of nerve changes both coarse and subtle, but all degenerative in type. With these therapeutics had not and could not keep pace, although doubtless during the present century clear and distinct advances had been made in the treatment of disease. A notable example of this was found in the treatment of syphilis. In former times, yet within the memory of middle-aged men, it was not uncommon to see the recrudescence of this malady years after its initial signs and supposed elimination from the body. It was not considered necessary to prolong treatment much beyond the disappearance of the local sore and its induration, or at most after the disappearance of secondary symptoms, as they were commonly called. Dr. Brookhouse believed that the more careful clinical observation of comparatively recent times, which has resulted in the prolonged treatment of the disease by mercury and other specific remedies, has materially altered and improved our statistics, and that now it is somewhat exceptional to see its reappearance. The treatment of the restlessness with delirium in sthenic pneumonia afforded another example of advance. It was for those engaged in clinical observation to supplement the work of the chemist and pharmacologist who introduced new remedies. In conclusion he brought forward his experience regarding the use of menthol in the treatment of pulmonary phthisis. The method he adopted consisted in the introduction once or twice daily into the trachea of one drachm of a 12 per cent. solution of pure menthol in pure olive oil. This he effected with the aid of the laryngoscope and a syringe specially made with a curved tube; the tube is passed through the rima glottidis, about half an inch down the trachea. After a little practice and habituation the patient feels no inconvenience or discomfort whatever; on the contrary, there arises an agreeable sense of warmth in the chest. One very early result is a marked diminution of the cough and expectoration; the night sweats, if previously existent, cease, the hectic temperatures become much less marked, the curves often go to the normal, and the patient gains in weight.

Dr. BROADBENT opened a discussion on the subject of Cardiac Tonics and the indications for their Use. He restricted the paper to the discussion of the use of the so-called cardiac tonics, and did not touch upon what he expressed himself as feeling to be even more important in treating diseases of the heart—namely, rest, graduated exercise, and the elimination of waste products. He also spoke of the difference between these remedies in their action. It was claimed on the best authority for strophanthus, he said, that it increased the force of the systole of the heart without increasing the contraction of the arterioles. He did not find that drug to be as generally useful as digitalis in cardiac disease probably due to the fact that the preparations of strophanthus were not uniform, and a large proportion of them were comparatively inert. Occasionally however where digitalis failed to produce an effect or where it could not be tolerated strophanthus produced excellent results. Caffein was said to increase the solids in the urine while digitalis increased the fluids. That was not borne out by his own experience. The practical point at which he had arrived was that caffein and digitalis together would do a great deal more than could be accomplished by merely increasing the dose of digitalis alone. There was some difference in the action which made caffein an exceedingly valuable supplementary heart tonic.

Dr. LAUDER BRUNTON said that Dr. Broadbent had shown admirably how digitalis acted in affecting both the heart and the vessels. In digitalis as commonly used there is a curious combination of substances, because apparently digitaline and digitoline have more or less an antagonistic

action, the digitaline tending to cause strong contraction of the involuntary muscular fibres both in the heart and in the vessels, whereas digitoline tended rather to counteract this action. Where there is excessive contraction of arterioles in cases of cardiac disease it is well to combine with digitalis some other substances which tend to dilute the vessels—for example, the spirits of nitrous ether. One of the directions in which modern pharmacological research is likely to give aid in treating patients is in the discovery of some substances which would tend even more than strophanthus to contract the heart more powerfully than the bloodvessels. One such substance appears to be oxy-sparteine which acts strongly upon the heart, but very slightly upon the vessels, and in cases where digitalis does not act we find strophanthus seems to exert too strong an influence upon the vessels where the heart seems to be very weak in comparison to the resistance which has to be overcome. We may find that a substance like this could take the place of such a combination as digitalis and nitrous ether or strophanthus and spirit of nitrous ether. In cases of men who are accustomed to take alcoholic stimulants continuously and whose heart begins to fail, digitalis seems to have very little effect indeed either in increasing the force of the heart or in slowing it. This was rather in favour of the idea that digitalis did not act purely and simply upon the cardiac muscular fibre and that it has a certain action on the heart through the vagus. Experiment seems to show this to some extent, because in animals, when the heart is slowed by means of digitalis, its rhythm is very considerably affected by cutting the vagi. The heart was not always found to be in a state of tonic contraction. In a dog, which poisoned itself with digitalis leaves the heart became slowed to six per minute before death, and after death it was found to be in a state of diastole. One of the benefits which arises from digitalis is prolongation of the diastole, the period of rest both of the ventricles and the auricles. If the vagi be cut and intra-cardiac pressure thereby increased the heart almost immediately begins to beat very much more quickly than before, and therefore if we have increase of tension within the vessels we tend to counteract the restful influence of digitalis and the other cardiac tonics. Muscular exertion is, as everyone knows, a factor which increases the tension within the heart, and obviously if we wish to get the restful heart which we desire for its recovery from over-strain one of the best things we can do is to put the patient completely at rest. There is no mode of treatment of cases of mitral disease which seems to yield more satisfactory results both for the patient and the doctor than *complete rest*. As an adjunct to complete rest in bed, massage is of great use. It increases the nutrition of the patient without putting any strain upon the heart. When the patient recovers you wish him to get more than the passive exercise of massage, and at the same time you feel uncertain about allowing him to go outside and walk about. There is no doubt whatever that the treatment by graduated exercise is very useful, but it has the disadvantage of being difficult to prevent the patient from overdoing it. Dr. Brunton showed an "ergostat" which has been invented by Professor Gärtner of Vienna and which can be so adjusted that the resistance to the force of the patient could be increased or diminished at will. Another point to be noted was that of elimination. The waste products of muscular tissue gave rise apparently to a certain amount of contraction and also seemed to interfere with the action of the heart in the interchange between the blood and the tissues. As a result of mitral disease very often the liver is enlarged and the patient's general condition is improved by a purgative such as blue pill at night followed in the morning with a compound jalap powder. The combination of these points in the treatment would prove very beneficial.

Dr. CLIFFORD ALBUTT thought the knowledge on the subject was as yet very rudimentary and somewhat obscure; by the use of cardiac tonics the potential equilibrium might be attainable, but it had no good chance until the back reckonings were cleared away. He ventured to think that the "ergostat" would be an exceedingly dull performance and suggested that some kind of musical instrument might be attached to the handle.

Professor EBSTEIN joined in the discussion.

Professor OLIVER thought it mattered very little in the first instance what was the primary lesion of the heart, because the immediate effect of any lesion was to overload the heart with work. He maintained the utility of digitalis in aortic regurgitation.

Dr. LINDSAY said he would confine himself to general impressions, omitting details. He had tried digitalis and strophanthus largely, convallaria and caffeine much less often, casca and sparteine not at all. He regarded digitalis as much the most valuable of the group.

Dr. A. J. HARRISON made a few remarks about the point of absolute rest in cardiac diseases and especially in aortic regurgitation. By rest he meant absolute rest in bed for a period of six months. A case was related in which a girl with very marked aortic disease (double) was much benefited by this plan. At the commencement the girl was pale, anæmic and restless, the apex beats being two inches outside the nipple line. At the end of the time the heart beat was half an inch inside the nipple line. The appearance of the patient was markedly improved; she had colour in her cheeks, had gained flesh and was able to take gentle exercise with comfort and this condition was continuing when she was last seen a few weeks ago.

Dr. STOCKMAN drew attention to certain points in the action of digitalis in health and in cardiac disease mentioned by Dr. Brunton—viz., after poisoning a dog with digitalis its heart was found in diastole. Now if small enough doses are given this is invariably the case. The first effect of digitalis is to prolong the diastole and during this stage the heart chambers are better filled, but the blood pressure is only slightly raised or possibly not at all. In cardiac failure the symptoms which distress the patient are chiefly dyspnoea and dropsy, both of these being due to insufficient filling of the arteries and overfilling of the veins. If this be put right by any means the patient is relieved. Rest suffices often and therefore the blood pressure does not necessarily require to be raised, but only a redistribution of the blood is effected. Dr. Broadbent mainly lays stress on digitalis increasing the propulsive power of the heart, speaking of the left auricle as if it were quite passive, but it must be remembered that it shares in the slowing and therefore gets more time to propel its contents into the left ventricle and thus assist in restoring the balance of the blood distribution. In any forms of valvular lesions, where the blood is not properly distributed, digitalis, it seems to me, will do good if not given in too large doses. The bad results often obtained are probably frequently due to excessive doses.

Dr. BROADBENT, in replying, had no doubt that under certain conditions the amount of ventricular dilatation with aortic regurgitation would indicate digitalis being useful. The amount of regurgitation may be small, but the heart much dilated because of the habits and work of the patient. The action of the left auricle is merely passive; and the right side, where venous pressure is less and external influences more obvious, the contraction of the right auricle would be of service. It does not necessarily follow that because arteries are badly filled veins are too full, and in some cases aortic regurgitation might be first signalled by the patient dropping down dead, or by attacks of giddiness.

The Section then adjourned.

#### LARYNGOLOGY.

In this Section the President was Dr. HAYES (Dublin). He first thanked the members for the honour done to him and welcomed Professor SCHRÖTTER of Vienna and other distinguished visitors to the section. The first discussion was on the subject of the Etiology, Pathology, and Treatment of Nasal Neuroses, introduced by Mr. DONALD STEWART, who furnished an excellent bibliography of the subject, recounting observations from some 250 different observers. Both papers were deservedly well received. Throughout the discussion considerable variety of opinion was expressed as to the advisability of general as opposed to local treatment. A consensus of opinion, however, seemed to tend towards the statement that in certain cases local evidence was quite sufficient to account for the nervous phenomena. Professor SCHRÖTTER communicated a paper on the subject of Nervous Affections of the Throat, which consisted of a series of observations of three rare neuroses. While, of course, no one could question the excellence and accuracy of the distinguished Professor, still Dr. FELIX SEMON suggested another explanation to account for the observations. Professor SCHRÖTTER, in reply, said that they could not explain everything they saw in nature or in medicine, but the facts were as he had stated them. Some other papers followed.

#### THE EXHIBITS.

The museum of the British Medical Association has a special feature attached to it this year in the shape of a Sanitary Exhibition, which was to have been opened on Tuesday, the 26th inst., by Sir Walter Foster, M.P., who was prevented through a slight illness from attending. The President-elect of the Association, Mr. Joseph White, officiated in his stead. In opening the exhibition he said that for many years it had been the custom of the British Medical Association to have a museum showing the advance of medical knowledge in its application to sanitary science. This year it had been attempted to extend that department, and it was peculiarly appropriate that it should be at Nottingham that this departure should have been made, because Nottingham had stood in the front rank of those towns which had seen the importance of sanitary work and which had tried to improve the defects of ancient methods.

The Mayor of Nottingham, Alderman Blackburn and Dr. Boobyer, medical officer of health for Nottingham, also spoke.

In the exhibition there were in all nearly fifty stalls, on which the exhibits were placed, and in looking round them we note the various stalls as follows:—Stall 1: The Anidjah fire-escape, which consists of a tubular arrangement by which descent can safely be made from the highest building. The upper part of the tube is constructed of asbestos strengthened inside by metal bands and thus is protected from the action of fire. Stall 2: A Nottingham School Board exhibited a desk and seat, the construction of which is designed to promote an erect posture. Stall 3: Messrs. Emerson and Franks exhibit among other goods Dr. Boobyer's hospital locker, consisting of a small cupboard with drawer and trays surmounted by a cover, projecting downwards at the sides, and which serves the double purpose of a bed-table and shelf for food, medicine &c. This has been adopted in a Nottingham general hospital and in several other hospitals in the provinces. Stall 4: Messrs. Boyd and Co., Belfast, here exhibit their well-known doctors' ulsters and other goods. Stall 5: Messrs. John Humphreys and Co., Limited, of the Cavalier Soap Works, Nottingham, show as specialities their dry and paraffin soaps. Stall 6: Mr. W. Cook of Lenton Boulevard shows a twin pump and condensing engine for use in lifting water to great altitudes, and also artesian well apparatus. Stall 7: Messrs. Hughes and Lancaster, Great George-street, Westminster, exhibit a working model of the "Shone" hydro-pneumatic system of sewerage. Stall 8: Messrs. Foster and Cooper of Long-row, Nottingham, exhibit on their own account a large variety of hospital furniture as supplied to the General Isolation Hospital at Nottingham; for Messrs. Isaac Chorlton and Co. they exhibit operating tables, hospital bedsteads, bed-rests and other like specialities; and for Messrs. L. P. Whitfield the "Lawson-Tait" bedstead. Stall 9: Mr. H. Sulley, Wheeler-gate, Nottingham, shows his patent noiseless safety glass floors and pavement lights. Stall 10: Messrs. Duckett and Son, Burnley, display their well-known waste waterclosets in six varieties. These closets are all erected and in working order, so as to exhibit all working and structural details. Stall 11: Messrs. John Parker and Hassal, of Nottingham and London, show their safety joint for drain and other pipes, which is now used by some 150 local authorities in England and Wales alone. Stall 12: Mr. W. E. Allen, Gravelly-hill, Birmingham, shows automatic flush closets in several varieties. These closets are in working operation. Stall 13 contains an exhibit by Price's Patent Candle Company of candles which are stated to contain no organic or metallic impurities; they also exhibit soaps and disinfectants in many forms. A considerable number of exhibits arrived after the catalogue had been completed. (This account will be continued in our next issue.)

#### IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE provincial general meeting of the above Association, which now numbers nearly 700 members, was held on Wednesday, July 27th, at University College, Nottingham. In the absence of the President, Director-General Dick, C.B., R.N., Dr. Heath of St. Leonards was called to the chair. There

was a large attendance of members. The Council reported that since the anniversary meeting a signal victory over the monopolists of hospital appointments had been achieved at Hastings, where, by a majority of 78 to 33, the governors of the East Sussex Hospital had repealed the rule restricting honorary staff appointments to those holding London diplomas.

Professor Cuming, M.D. (Belfast), proposed, Dr. Douglas (Leamington) seconded and it was unanimously resolved: "That the Association records its satisfaction at the success of the Council's proceedings in reference to the rule formerly in force at the Hastings and East Sussex Hospital by which diplomates of the Irish Royal Colleges of Physicians and Surgeons were excluded from competition for honorary appointments on the staff of that institution." The Council also reported that Lord Sandhurst's Committee had published as an appendix to their lately issued report to the House of Lords a statement prepared on behalf of the Association setting forth the injustice of the restrictive rule as it exists still in the greater number of the large London hospitals. A vote of thanks to the Chairman concluded the proceedings.

## ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1890; WITH APPENDIX. VOL. XXXII., 1892.<sup>1</sup>

### [FIRST NOTICE.]

THE army medical report has been issued rather earlier this year than usual. It consists of 391 pages, 71 of which are in the form of an appendix to the report and contain papers on the Progress of Hygiene for the year 1891, a report from the medical and surgical divisions of the Royal Victoria Hospital, Netley, a paper on the Etiology of Malta Fever, and another on Six Cases of Lightning-stroke. The great bulk of the report therefore consists of the vital statistics of the troops at home and abroad and matter concerning the sanitary conditions by which they are surrounded. As the primary and fundamental object in the publication of these reports is for the information of the Houses of Parliament this must necessarily be the case and very properly so. But we think it is to be regretted that the more strictly professional and scientific portion of the volume appears to be a diminishing quantity. Medical officers scattered all over the world have so many opportunities of making original and interesting observations that we are curious to know what are the new diseases, if any, they have encountered and how those with which we are familiar at home comport themselves abroad under different conditions of climate, to say nothing of observations in medico-topographical reports on natural history, anthropology, climatology and the like. The departmental reports of the past contained many really valuable contributions to our knowledge in various directions. Without doubt the statistical portion of this volume is ably executed; the information is full, clearly arranged, and almost every point capable of being illustrated or elucidated by figures has been turned to account. But statistics and reports dealing with the sanitary details of places with which the reader has probably no personal acquaintance are not mentally more palatable than a water-free food diet would be. The point which is looked for is apt to be lost in a multitude of figures and ratios, and it is not always possible to say whether all the figures are really relevant to the subject to be elucidated. Statistically considered, however, these reports are admirable; and we should like to be able to say the same of the papers in the appendix in regard to their number, variety and quality.

With these few prefatory remarks let us now turn to the volume itself. The average annual strength of the troops serving at home and abroad in 1890, as computed from the returns, was 196,502 warrant officers, non-commissioned officers and men (exclusive of colonial corps); the admissions into hospital in this force were 208,014 and the deaths 1787. The rates represented by these numbers are for admissions into hospital 1058.6, and for deaths 9.02 per 1000 of the average annual strength, calculated as 198,154, which in-

cludes detached men. For the previous ten years (1880 to 1889) the ratios per 1000 of troops serving at home and abroad were for admissions into hospital 1058.2 and for deaths 10.28.

Examining the tabular results of sickness in the different commands we find that the mortality-rate per 1000 among troops quartered in the United Kingdom for the year 1890 was 5.53, at Gibraltar it was only 3.22, at Malta 9.77, in Egypt 12.47, 13.58 in Bermuda, nearly the same in Mauritius and 14.45 in India. Compared with the results for the ten years from 1880 to 1889 the death-rate per 1000 for troops serving in the United Kingdom was 6.10, in Gibraltar 6.13, Malta 8.66, Bermuda 10.04 and 15.66 for India, whilst the mortality rate for Egypt for the seven years 1883-89 was 25.66. The average strength of the troops serving in the United Kingdom during the year 1890 was 100,120, to which men detached from these corps, computed to average 1652, have to be added. For the United Kingdom, taken as a whole, the admission ratio was 810.6, the death-rate 5.53, the invaliding rate 16.72, and the constantly sick rate 44.29 per 1000 of strength. Compared with the corresponding ratios for the preceding ten years, a decrease is observed in all the rates of sickness and mortality, but there is a slight increase as compared with the results of the previous year. The total loss by death and final discharge from the service on account of medical unfitness was 2265 men, being in the ratio of 22.25 per 1000 of strength, which is higher than the ratio in the previous year by 1.79. Adverting to some of the more important statistics of sickness mortality and invaliding among the troops in the United Kingdom it is satisfactory to learn that there was not one case of small-pox recorded in the year. Out of 243 admissions for scarlet fever 225 occurred in England and Wales, none in Scotland, and 18 in Ireland. The greatest number of cases in any one station was 80, at Woolwich, of which one proved fatal; the disease was also very prevalent among the civil population. At Aldershot there were as many as 75 cases with 1 death, and at Devonport 28 cases with one death. These three stations gave three-fourths of the total number of admissions, the remaining fourth being scattered among as many as twenty stations.

As regards enteric fever the admissions numbered 126 and the deaths 30. The admission ratio was 1.3 and that of mortality 0.29 per 1000. The percentage of mortality to attacks was 2.39, as compared with 17.8 in the previous year and 23.1 the average for ten years. In Scotland there was only one admission from this disease, but that terminated fatally; the admission ratio was 0.3 per 1000. In only one of the administrative districts in England—viz., the Thames district—was there complete immunity from this disease and the number of stations in which it appeared was 30. As in several preceding years, the station showing the greatest prevalence of the disease was Dublin, but in this respect the year under report compares favourably with the preceding year, as the number of cases and deaths were 34 and 6 respectively, as against 63 cases and 8 deaths. This great decrease in the number of attacks is due to the fact that, on account of the notorious prevalence of enteric fever in the Royal barracks they were evacuated quite early in the year. Excluding the Royal barracks, the number of cases from the remaining barracks continued the same. The disease seems to have appeared in nearly all the barracks in Dublin, and the sanitary condition of some of them was considered so unsatisfactory that they were evacuated. This looks as if some extensive sanitary engineering works required to be undertaken for the disposal of the sewage of the city of Dublin as a whole. The station which shows the next largest number of cases is Aldershot, where there were 18 admissions and 4 deaths, as compared with 8 admissions and 1 death in the previous year. The cases came from different parts of the camp. At Caterham there were 15 attacks and 2 deaths; the cases came from four blocks of barracks and the outbreak was probably attributable to certain important sanitary defects, which were discovered and rectified.

Just at the close of the year 1889 a few cases of influenza had appeared in England, which were the commencement of the epidemic that spread all over the country within the first three months of the following year. The total number of admissions was 6584, with eight deaths. The ratio of admissions was 65.7 and that of deaths 0.08 per 1000. Every district was more or less affected with the disease, but the greatest number of cases occurred in the Home District. Influenza also appeared among the troops stationed in India and the colonies; in fact, throughout our foreign commands. Taking all forms of venereal disease together, the admis-

<sup>1</sup> London: Printed for H.M.'s Stationery Office, by Harrison and Sons, Printers in Ordinary to Her Majesty.

sions in the United Kingdom for these complaints numbered 21,262 and the constantly sick 1709.35. The total ratio of admissions was 212.4 per 1000, which differs only fractionally from the corresponding rate in the previous year, but is below the average rate for the preceding five years by 32.8. Under the head of "poisons" it may be incidentally remarked that there were eight admissions and two deaths. Two of the cases were of poisoning by oxalic acid, taken with suicidal intent, one of which proved fatal, and there was a fatal case of suicidal poisoning by cyanide of potassium. There were 21 cases of suicide during the year among the troops serving in the United Kingdom, as against 17 in the preceding year, the average number for the previous ten years being 20. The number of men discharged the service during the year as medically unfit was 1,702, being in the ratio of 16.72 per 1000, which is rather higher than the corresponding rate of the previous year, but lower than the average rate for the preceding ten years by 2.82 per 1000.

We must refer the reader to the tables showing the influence of age and length of service on sickness, mortality and invaliding among the troops serving in the United Kingdom during the year 1890. As might, we think, be expected the occurrence of sickness was greater among young soldiers than older ones, the mortality rate, on the other hand, being very low among men in their first year's service and the invaliding ratio being also low. The sick rate shows a steady decline during the third, fourth and fifth years of service, followed by a slight rise among men of between five and ten years' service and falling again considerably among men over that period of service.

There is an interesting table showing the statistics of sickness and mortality among troops quartered in the large camps at Aldershot, Colchester, Shorncliffe and the Curragh, as compared with those of troops quartered in thirty-seven large towns where the average strength was over 500 non-commissioned officers and men. According to the table the admission- and constantly-sick rates of men in camps differ very slightly from those among men quartered in towns. The mortality rate was a good deal higher among men quartered in towns than among men quartered in camps. This was also the case in the preceding year, but to a less extent.

## THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A MEETING of the committee of the Association of Fellows of the Royal College of Surgeons of England was held at 5 P.M. on Thursday, July 21st, at 36, Grosvenor-street. Mr. George Pollock, the President, occupied the chair, and there was a full attendance of members of the committee. Mr. Vincent Bell of Rochester and Mr. J. J. Parnell of Streatham were introduced as new members of the committee. The minutes of the last meeting having been read and confirmed, letters expressing regret at being unable to attend were read from Mr. Holmes, Mr. George Jackson of Plymouth and Mr. G. F. Helm of Truro. A report was presented by the honorary secretary, Mr. Percy Dunn, in reference to the recent meetings and the annual dinner. After the payment of the expenses of the dinner a small balance remained and was handed over to the treasurer for the general fund. Some discussion ensued about holding a dinner in 1893 in consequence of the arrangements which have been made by the Council of the Royal College of Surgeons for a Fellows dinner on the occasion of celebrating the jubilee of the Fellowship. The decision of the matter was deferred. A similar result was arrived at in reference to certain points of reform at the College, such as the mode of procedure at meetings at the College &c., it being considered advisable not to press these matters upon the Council for the present.

Two letters from Mr. Holmes addressed to the President were read by Mr. Pollock. They referred to an incident which occurred at the meeting of Fellows of the College on the 7th inst. and to a collateral matter of some importance to the Association arising out of that incident. A prolonged discussion ensued upon these topics and ultimately a letter was drawn up to be signed by the President and Honorary Secretary of the Association and to be forwarded to the official referred to in Mr. Holmes's letters. The object of the

communication was to secure the correction of a misstatement which affected the Association. Further action was deferred till the next meeting of the committee.

On the motion of Mr. W. Allingham, a vote of congratulation to Mr. John Tweedy on his recent triumphant election to the Council of the College was unanimously passed. In thanking the committee for their congratulatory vote Mr. Tweedy said that he had been greatly influenced in persevering in the reform movement and continuing to work on the committee of the Association by the example set by Mr. Pollock as President of the Association. He hoped to be able to act on the Council of the College in accordance with the views and principles which he had supported in the committee of the Association. There being no other business the committee adjourned at 6.30 P.M.

## FOUNDER'S DAY AT EPSOM COLLEGE.

THE annual ceremony of perpetuating the memory of the late Dr. Probert, the founder of the Epsom Medical College, with which is associated the annual distribution of prizes to the boys, took place on Monday last. Favoured with fine weather, there was a large attendance of parents and friends. The head master, the Rev. T. N. Hart Smith, M.A., presided, and was supported by Dr. Lumsden Probert, son of the founder, Dr. Holman (treasurer), Sir Joseph Fayrer, K.C.S.I. (chairman), Sir Edward Sieveking, M.D., and other members of the council.

Prior to the distribution of the prizes the Head Master delivered a lengthy speech, in the course of which he reviewed the work of the school and the achievements of the scholars during the past year. He said they could point to a year of healthy progress, and he would like to say how thoroughly satisfied he was with the discipline of the school. They had had a fairly clean bill of health, but unfortunately they had to record many a sad loss from death. The council had supported the extension of the museum, and they had a most flourishing rifle corps, the members of which numbered seventy. The College was asking to be recognised as a school of science on the grounds that the teaching is sufficient, as shown by the list of distinctions gained, and it possessed all the requisites for science teaching. Recently out of ten boys who went in for the Preceptor's Scholarships nine passed, and out of twenty-seven boys who went in for the Cambridge Local Examinations twenty-one obtained certificates. One of the great disadvantages of the present system was that those boys who most required the discipline and teaching of school were very often sent up to the hospitals of London before they were really fit to go to them. If some means could be adopted to keep those boys and train them to pass the first examination, which they had to pass in London before they left school, he believed the advantages would be much greater than those of the present system. Six scholarships had been won by the College at Cambridge during eighteen months, and they had also passed two boys direct into the army class. He would be very sorry, however, if the application on their part that the school should be registered as a school of science should lead anyone to suppose that they wished to make any difference as to classical teaching. He felt and was sure that the members of the council considered that the school must always be conducted on a classical basis.

The awards were then handed to the successful scholars by the Head Master, the Probert Prize being presented by Mr. Lumsden Probert to F. G. Thompson and P. Levick, between whom it was divided, each receiving a bronze medal and £10. The scholarship of £50 a year called the Harvey Owen Scholarship, which had become available for the first time on this occasion, had been awarded to P. Levick, and the Doncaster Gift Scholarship to Senior Prefect F. G. Thompson.

Dr. HOLMAN expressed his delight at hearing such an excellent account of the work of the school. It was not the case, he said, of a new broom sweeping clean, as Mr. Hart Smith had not only begun to work when he came there, but had continued to work with great success. That school had won a repute for Epsom. A free medical scholarship to the London Hospital had been given to it that day and he congratulated the College upon the fact.

Sir JOSEPH FAYRER also addressed a few observations to

the scholars and congratulated the Head Master on the success the school had achieved.

The large company shortly afterwards adjourned to the lawn, where light refreshments were served.

## MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE fifty-first annual meeting of the above Association was held on July 21st at The Retreat, York, in honour of the centenary of the foundation of that institution. The proceedings commenced at eleven o'clock by a general meeting of members for the receipt of reports, the election of officers and the transaction of other business. Dr. Yellowces moved the following resolution: "That the Medico-Psychological Association of Great Britain and Ireland, assembled in its annual meeting at the York Retreat, desires to place on record its admiration of the spirit which animated William Tuke and his fellow workers a hundred years ago, its appreciation of the mighty revolution which they inaugurated, and its thankfulness for the beneficent result which their example has secured in the humane and enlightened treatment of the insane throughout the world." Various matters were discussed and committees were appointed to revise the rules and the question of proxy voting, to consider and report on the subject of public asylum dietaries, and to compile and reissue a handbook of instruction to attendants and nurses on the insane. It was resolved—"that a copy of the report of the Care and Treatment Committee be sent to each County Councillor and to each member of Committees of Asylums not managed by County Councils within the United Kingdom"; that application should be made to the Home Office for the prefix of the word "Royal" to the name of the Association; and that a board of education be appointed to consider all questions affecting medico-psychological teaching. Suggestions were also presented from a committee for the improvement of the rules for the training, examination and certification of attendants and nurses on the insane; these were discussed and for the most part agreed to. Dr. Needham and Dr. F6ré were elected honorary members. After luncheon, provided by the Retreat Committee, Dr. Baker, the President, delivered his address. He took for his subject Hospitals for the Insane, their power and influence in the treatment of mental ill-health. He considered that such hospitals were factors for good in two distinct ways: (1) They possess, or ought to possess, every possible power and appliance for the care, treatment and cure of the insane, and everything that brains and money can obtain; (2) all the money obtained from the remunerative patients being spent liberally and impartially in promoting the welfare, comfort and cure of the patients who are not remunerative, whether they pay anything or nothing. As a means towards the first object special accommodation for special cases of mental illness had been made and numerous villas had been built in the grounds of the hospital; an increased number of resident medical officers had also been appointed. In the evening the members and a number of invited guests, among whom were Dr. Morel (Belgium), Dr. Semchaigne (great-grand-nephew of the illustrious Pinel) and the City Sheriff dined at the Station Hotel. Numerous letters of regret for non-attendance and congratulations to the Association and the Committee of the Retreat on the completion of the centenary of its foundation from official bodies at home and abroad were read by the honorary secretary, Dr. Fletcher Beach.

## ROYAL BRITISH NURSES' ASSOCIATION.

THE fourth annual meeting of this Association was held in the Pavilion at Brighton on July 21st. Dr. Hollis, F.R.C.P., took the chair and a considerable number of members were present. The annual report of the General Council, presented by Dr. Bezly Thorne, showed that there were 2818 members now on the roll and more than 1800 on the register of trained nurses, the second volume of which was published in January. Reference was made to the petition presented by Princess Christian, the President, for a Royal Charter of incorporation

for the Association, and Her Royal Highness's constant interest and support were warmly acknowledged. It was pointed out that the select committee of the House of Lords in their report had expressed their opinion that no woman should be sent out as a private nurse unless she had received three-years' hospital training, thus corroborating the standard which the Association had from the first adopted and for which it had been so very strenuously opposed. As all hospitals will probably now adopt this standard it was confidently hoped that the opposition to the Association would soon disappear. The good work done by the Association in giving pensions and pecuniary grants to its members who were in indigence or temporary difficulties, and the steadily increasing support accorded to its registration scheme by medical men all over the country, were commented upon. Dr. Bedford Fenwick presented the audited accounts, showing that the Association had in four years made investments amounting to £1340, that the balance in hand was £255 and that all the schemes of the Association except the register were now more than self supporting. Various alterations were made in the by-laws which, amongst other things, provided that the General Council, which is the governing body and which consists of 100 medical men, 100 hospital matrons and 100 sisters and nurses, should be elected by voting papers sent to all the members in May of each year. Votes of thanks to the Mayor and corporation, the committees of the Sussex County Hospital and of the Home of Rest for Nurses, to others who had offered hospitality to the Association and to the chairman concluded the meeting. Luncheon was then served in the Banqueting Hall of the Pavilion, at which the Mayor (Dr. J. Ewart, F.R.C.P.) took the chair. After proposing the healths of the Queen and of the President of the Association the chairman gave the toast of "The Nursing Profession." He welcomed the Association to Brighton and warmly congratulated it upon the important public work in which it was engaged, and noted the opposition with which it had been met as a further proof of the value and necessity of its work. He thought that it was most fortunate that its opponents had prevented it from becoming registered under the auspices of the Board of Trade, as the importance of its work and of the nursing profession as an integral part of the medical profession demanded that the Association should be considered as something higher than a mere limited liability company. He felt confident that all medical men who learnt what the Association was doing in attempting to afford them and the public some means of distinguishing trained nurses from ignorant and incompetent women who called themselves such and to bring the whole nursing profession under professional control would give the Association their cordial support and assistance. Whether the Association obtained a Royal Charter this time or not he thought would matter very little, for if it persevered in its valuable work it would undoubtedly succeed, as truth always succeeded in the end; and it would obtain all the more support and sympathy the more it was opposed. The toast of "The Chairman" having been duly honoured the proceedings terminated. The members spent the rest of the day in various sea and inland excursions which had been planned for them on the invitation of the committee of the Sussex County Hospital, then inspected that institution and had afternoon tea in the garden, and later in the day enjoyed the hospitality of the Nurses' Home of Rest in Sussex-square.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6303 births and 3467 deaths were registered during the week ending July 23rd. The annual rate of mortality in these towns, which had been 17.1 and 17.9 per 1000 in the preceding two weeks, declined last week to 17.7. In London the rate was 19.0 per 1000, while it averaged 16.8 in the thirty-two provincial towns. The lowest rates in these towns were 11.1 in Cardiff, 11.5 in Portsmouth, 12.1 in Brighton, and 12.8 in Bradford; the highest rates were 19.9 in Hull, 20.1 in Birkenhead, 21.3 in Blackburn, and 21.5 in Bolton. The 3467 deaths included 625 which were referred to the principal zymotic diseases, against numbers increasing from 477 to 598 in the preceding four weeks; of these, 282 resulted from diarrhoea,

135 from measles, 81 from whooping-cough, 53 from diphtheria, 41 from scarlet fever, 27 from "fever" (principally enteric), and 6 from small-pox. No fatal case of any of these diseases occurred last week in Burnley; in the other towns they caused the lowest death-rates in Newcastle-upon-Tyne, Swansea and Wolverhampton, and the highest rates in Croydon, Leicester, London, Preston and West Ham. The greatest mortality from measles occurred in Huddersfield, Sunderland, West Ham and Halifax; from whooping-cough in Portsmouth, Salford, Croydon, Hull and Preston; and from diarrhoea in Blackburn, Croydon, Norwich, London, West Ham, and Leicester. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 53 deaths from diphtheria included 37 in London, 4 in Birmingham, 4 in Manchester and 2 in Liverpool. Four cases of small-pox were registered in London, 1 in Halifax, and 1 in Sheffield, but not one in any other of the thirty-three large towns; 11 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 4 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2671, against numbers increasing from 1226 to 2488 on the preceding seventeen Saturdays; 382 new cases were admitted during the week, against 301 and 323 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 185 to 168 in the preceding three weeks, further fell to 158 last week, and were 24 below the corrected average. The causes of 69, or 2.0 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Nottingham, Oldham, Sunderland, Newcastle-upon-Tyne and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Bristol, Birmingham and Liverpool.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 19.3 to 17.2 per 1000 in the preceding four weeks, rose again to 18.4 during the week ending July 23rd, and was 0.7 per 1000 above the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 6.9 in Perth and 10.4 in Leith to 20.0 in Edinburgh and 21.8 in Dundee. The 512 deaths in these towns included 28 which were referred to measles, 13 to whooping-cough, 10 to diarrhoea, 5 to scarlet fever, 5 to diphtheria, 5 to "fever" and not one to small-pox. In all, 66 deaths resulted from these principal zymotic diseases, against 62 in each of the preceding two weeks. These 66 deaths were equal to an annual rate of 2.4 per 1000, which was 0.8 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had declined in the preceding four weeks from 35 to 13, rose again to 28 last week, of which 25 occurred in Glasgow. The deaths referred to whooping-cough, which had declined from 27 to 18 in the previous four weeks, further fell to 13 last week and included 6 in Glasgow and 4 in Edinburgh. The 10 fatal cases of diarrhoea showed a decline of 6 from the number in the preceding week and included 6 in Glasgow and 3 in Edinburgh. The deaths from diphtheria, which had been 3 and 7 in the previous two weeks, declined to 5 last week, of which 3 occurred in Glasgow. The 5 fatal cases of scarlet fever were within 1 of the number in the preceding week and included 2 in Glasgow and 2 in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had been 71 and 65 in the preceding two weeks, further declined last week to 59, and were 21 below the number in the corresponding week of last year. The causes of 69, or more than 13 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21.8 and 24.2 per 1000 in the preceding two weeks, declined again to 19.8 during the week ending July 23rd. During the first three weeks of the current quarter the death-rate in the city averaged 21.9 per 1000, against 18.4 in London and 16.4 in Edinburgh. The 133 deaths in Dublin during the week under notice showed

a decline of 29 from the number in the preceding week, and included 7 which were referred to measles, 4 to diarrhoea, 2 to whooping-cough, and not one either to small-pox, scarlet fever, diphtheria, or "fever." In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.9 per 1000, the zymotic death-rate during the same period being 4.4 in London and 2.4 in Edinburgh. The fatal cases of measles, which had declined in the preceding five weeks from 27 to 9, further fell to 7 last week. The 4 deaths referred to diarrhoea exceeded the number in any recent week. The fatal cases of whooping-cough, which had been 2 and 0 in the preceding two weeks, rose again to 2 last week. The 133 deaths registered in Dublin last week included 24 of infants under one year of age and 36 of persons aged upwards of sixty years; the deaths of infants showed a decline from those recorded in recent weeks; while those of elderly persons showed an increase. Three inquest cases and one death from violence were registered; and 36, or more than one-fourth, of the deaths occurred in public institutions. The causes of 17, or 13 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

### THE CHAIR OF PATHOLOGY AT NETLEY.

To the Editors of THE LANCET.

SIRS,—Not holding a medical commission in Her Majesty's Imperial or Indian Army I am privileged, with your permission, to draw attention to the passing over of the medical officers of the Services in the election of a Professor to the Chair of Pathology at Netley. It is to be borne in mind that the probationers who enter here are qualified and have already gone through a very sound course of ordinary pathology; now, as I understand, this chair was instituted especially with reference to the instruction in and elucidation of the pathology of those diseases incidental to armies and those living in tropical and sub-tropical regions. There are in the Army Medical and Indian Medical Departments gentlemen of very considerable renown, distinguished graduates and diplomates of their universities and colleges, men who have had greater experience of the pathology of the kind of diseases just indicated than any others on the face of the globe. What inducement is there, Sirs, for young men of professional distinction, with the potentiality of and desire for original research, to enter a service which entails long-continued residence in dangerous climates when posts such as these, to which they would be legitimately entitled to aspire in the lapse of years, are handed over to civilians? Taking all these circumstances into consideration and not wishing in any way to be personal, I think all those who view the matter impartially will admit that the present appointment is not only an anomaly *per se* but an injustice *de facto*, and will agree with me in saying: *Palam qui meruit ferat.*

I am, Sirs, yours faithfully,

E. KENNETH CAMPBELL, M.B., F.R.C.S.

Lincoln's-Inn-fields, July 25th, 1892.

#### THE LATE MR. THOMAS COOK.

The late Mr. Thomas Cook, to whose death we referred last week, was buried the other day at Leicester. He was the enterprising originator of the famous tourists' ticket system and his name was probably better known than that of any man of his time. It is not, however, in this connexion that we here allude to his loss, but the energy and good work which the firm of Cook and Son displayed in Egypt on behalf of the sick and wounded soldier deserve a word of grateful recognition from medical officers in particular. After the campaign of 1882 the firm placed a number of their Nile steamers at the disposal of the military authorities in Egypt. They were equipped and fitted out with everything necessary for the sick soldier in a remarkably short space of time and rendered most excellent service. Nor was this the only occasion on which Cook and Son rendered effective aid to the army in Egypt.

#### PRESIDENCY OF THE INDIA OFFICE MEDICAL BOARD.

Surgeon-General Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S., retains his appointment at the India Office until January, 1895.

## ARMY RECRUITING.

The number of recruits inspected during the year 1890 was 55,367. Of these, 22,005, equal to a ratio of 397.43 per 1000, were rejected as medically unfit for the service, the remainder, 602.57 per 1000, being found fit.

## ALDERSHOT.

Anyone who has recently paid a visit to this camp must have been struck with the transformation that has taken place owing to the very extensive reconstruction that has been carried out. The principal medical officer states, according to the Army Medical Report for 1890, that the new brick huts are well constructed, with sufficient superficial and cubic space, and have an air of comfort and light about them, and the accessory buildings, such as wash- and cook-houses, latrines, &c., are well placed and in every way suitable. The new married quarters are very good and have ample accommodation. Surgeon-Major-General Faught adds that a new hospital is required for the North Camp and a considerable increase to the Cambridge Hospital to provide for the future requirements of the garrison, and he alludes to a difficulty that has arisen regarding a proposed site for the new hospital in the North Camp, on account of its proximity to the sewage farm, which is still under consideration.

## THE PHYSICAL EXAMINATION OF ARMY CANDIDATES.

As our readers may be probably aware, intending candidates for the Army about whose physical fitness there might be a doubt were frequently allowed to appear before a medical board as a kind of preliminary examination, with the view of obtaining the board's opinion or decision for the guidance of the candidate or his parents. It was obviously of material consequence to the candidate himself and those concerned about him that he should not needlessly waste his time and money in preparing for a career for which he was unfit on account of some physical cause or defect. This practice has, however, it is understood, been found to be attended with difficulties and the decision could not be regarded as final; consequently it has not been deemed expedient to continue the custom. The regulations as to the physical tests required of Army candidates should, it is considered, suffice for the guidance of candidates and medical men whom they may desire to consult on the matter.

## MOVEMENTS OF THE MEDICAL STAFF.

Surgeon-Lieutenant-Colonel W. P. Bridges has succeeded Surgeon-Lieutenant-Colonel Beamish in medical charge at Weedon. Surgeon-Lieutenant-Colonel Macpherson has rejoined at Portsmouth. Surgeon-Major Gormley has taken over the medical charge of the Station Hospital at Limerick. Surgeon-Captain Hardy has proceeded on leave from Dover. Surgeon-Captain Burrows has joined in Dublin for duty. Surgeon-Captain Rowan has left York on leave. Surgeon-Captain J. Will has joined the Home district for temporary duty. Surgeon-Captains Beevor and Jackson have left London for duty at Aldershot. Surgeon-Captain Braddell has left York for duty at Strensall Camp. Surgeon-Captain Whiting has left South Africa for Home on leave of absence. Surgeon-Captain Perry has arrived in Ceylon for duty. Surgeon-Captain Thompson has re-embarked for India.

The criticisms which have appeared in certain quarters upon the appointment of Dr. A. E. Wright to the Chair of Pathology at Netley seem to ignore two essential points. The first is that the civilian element has been recognised as a distinct feature of the professorial staff ever since the establishment of the Army Medical School, and the second is that a teaching body must not only be composed of capable men, but of the very best that can be secured. It is surely no slur upon the Army Medical Staff, but emphatically the highest compliment which could be paid to it is that from its limited numbers three out of four professorships are supplied by men attaining to the highest standard of excellence. For the rest, Dr. Wright's qualifications as a pathologist and as a teacher would be with difficulty excelled.

## ARMY MEDICAL STAFF.

The Queen has been pleased to give and grant unto Surgeon-Captain Richard Charles Kirby Laffan, Army Medical Staff, Her Majesty's Royal licence and authority that he may accept and wear the Insignia of the Order of the Osmanieh of the Third Class, which his Highness the Khedive of Egypt, authorised by his Imperial Majesty the Sultan, has been pleased to confer upon him in recognition of his services whilst actually and entirely employed beyond Her Majesty's

dominions in the service of his Highness as Inspector of Hospitals to the Egyptian Sanitary Department.

**NAVAL MEDICAL SERVICE.**—In accordance with the provisions of Her Majesty's Order in Council of April 1st, 1881, Surgeon Nicholas Charles Ridley has been placed on the Retired List of his rank, with a gratuity (dated July 13th, 1892).

## INDIAN MEDICAL SERVICE.

Surgeon-General Rice, Surgeon-General with the Government of India, goes on leave the first week in August.—Surgeon-Captain D. G. Marshall has been appointed to the officiating Medical Charge of the corps of Bengal Sappers and Miners, vice Surgeon-Lieutenant-Colonel J. Young.—Surgeon-Captain F. E. Murray, M.D., M.Ch., has been appointed to act as Civil Surgeon at Jacobabad, in addition to his own duties, to take effect from the 18th ult.—Surgeon-Captain R. Robertson has been appointed to act as Second Surgeon to the General Hospital, Madras, during the employment of Surgeon-Captain F. J. Crawford, M.D., on other duty.—Surgeon-General Pinkerton has been appointed an Additional Member of the Bombay Legislative Council for the remainder of the period for which Mr. Naylor, who has resigned, was appointed.

The Station Hospital for British troops in Alipur was struck by lightning on Tuesday, the 28th ult. The damage done was not very serious; one soldier patient, however, was hurt.

**VOLUNTEER CORPS.**—*Artillery*: 1st Argyll and Bute: Surgeon-Lieutenant J. Cunningham, M.B., to be Surgeon-Captain (dated July 23rd, 1892).—*Infantry*: 4th Volunteer Battalion (the Devonshire Regiment): Surgeon-Lieutenant J. R. Thomas, M.D., to be Surgeon-Major (dated July 23rd, 1892).—1st Surrey (South London): Surgeon-Lieutenant J. H. Edwards, M.D., resigns his commission (dated July 23rd, 1892); Walter Alexander Atkinson, M.B., to be Surgeon-Lieutenant (dated July 23rd, 1892).—2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Thomas Nesbitt Wright, Gent., to be Surgeon-Lieutenant (dated July 23rd, 1892).

## Correspondence.

"Audi alteram partem."

## "ASPIRATION IN PNEUMOTHORAX."

To the Editors of THE LANCET.

SIRS,—I was too much occupied with our University Final Examinations last week to be able to supply the few words which seem to me still needful, not indeed to form a full reply to Dr. Sutherland and Dr. Guthrie, but to enter a  *caveat*  against what still seems to me a dangerous error in practice. "Aspiration in Pneumothorax" is advocated on several grounds, which I may perhaps be excused, even by these gentlemen, for calling hypothetical, and into which I will not now enter as it would require a rather lengthened argument, with possibly a doubtful conclusion. But anyone can see that aspiration, so performed as "to produce such an exhaustion of air in the pleural cavity as would allow of the re-expansion of the sound lung, with return of the mediastinum and heart towards their normal position," must inevitably, and that suddenly, change the direction of the mechanical forces acting on the diseased lung, in the sense that, while before the operation the pressure was from without or on the surface of this lung, during and after the operation the pressure is reversed, the air tending from within outwards and towards the exhausted pleural cavity with a force exactly proportioned to that employed in the aspiration. Now, what happens after a quite recent pneumothorax, as I have ascertained in numerous instances, is this: the perforated pleura becomes overspread by a veil of soft lymph, which, when it gets fair play—i.e., when it is not torn up again and ruptured anew at every inspiration,—tends to seal up the opening and may even do so permanently, and thus allow of the air being in whole or in part reabsorbed. But when the aspirator comes into play to the extent indicated by Dr. Sutherland the very same traction which he expects to exert on the sound lung and mediastinum is at the same time, and quite unavoidably, exerted in a far greater degree and more directly on the diseased lung as well. Air rushes

in force along the still pervious bronchi and towards the pleural surface of this lung, just as it would do if one placed the lung under water and blew in the air from the main bronchus. If the lung were sound the aspiration would expand it again; but what happens instead—what must happen under the conditions supposed—is, that the perforation is opened up again and the kindly veil of lymph which nature was interposing is torn before it has had time to become organised and to seal up the opening. Apart from the theoretical questions raised by Dr. Sutherland, this seems plain enough; but I am not setting it forth as a theoretical risk, but as one which *I have known to occur*, not, indeed, in pneumothorax—for I have never aspirated in pneumothorax—but in pleuritic or empyematous effusions. I have known the aspiration of these *immediately* followed by pneumothorax, indicated by a succussion sound, which was not present before the operation. I therefore beg to repeat that in my opinion aspiration in pneumothorax is not a desirable or a safe practice, even in cases of urgency, and that if there is not pressure enough to cause the air to rush out spontaneously when a cannula is inserted fairly into the cavity there is no case for employing aspiration. If there is no urgency, it is better to leave well alone.

I am, Sirs, yours faithfully,

Glasgow, July 25th, 1892. W. T. GAIRDNER.

### "A NATIONAL DANGER."

To the Editors of THE LANCET.

SIRS,—Referring to my paper under the above heading which you kindly published in your last Saturday's issue, and to your leading article regarding the same, the widespread interest in the subject was manifested by leading articles in important north-country dailies and by an almost complete recapitulation of your leader and the contents of my paper. Your able editorial article, however, scarcely seems to me to grasp the situation as it at present exists in the manufacturing centres of the north. In these districts water is used for two purposes—viz., domestic and manufacturing, and by "chalking" the water as you suggest the industries of the districts would suffer. Then, again, even if the water were hardened, as you suggest and as proposed by many chemists, would its dangerous properties in relation to lead be destroyed? Personally I think not.

I remember some years ago walking through a field where there were some cows, in which a distinguished teacher of chemistry from a northern university had a financial interest. Coming upon the water trough, which was very large and lined with sheet lead, it was found coated with a sooty looking precipitate, which easily rubbed off on to one's fingers and stuck like blacklead. I ventured to suggest the danger of this water both to the cows themselves and also to consumers of their milk, and was met with the rejoinder that "it did not matter, the 'blacklead' did not mix with the water and did no harm unless stirred up." He said he would not hesitate to supply water for domestic purposes from leaden cisterns, provided they were not agitated, and that water containing less than one-tenth of a grain of lead to the gallon need not be condemned as unfit for drinking purposes. I regard the foregoing as a fair example of a non-medical chemical opinion. In considering the action of water on lead I believe we have to approach the subject from both a chemical and physical aspect, and I am not prepared to say the latter is not as important as the former. At the present moment (July 26th) I have standing before me a specimen of water from a neighbouring district, where lead-poisoning was said to be rife. I am informed that this water is now hardened with chalk; whether this is a fact or not I cannot say, but it acts like many other so-called hard waters. First let me state the test to which this water was subjected. On July 11th, to about half a pint of water was added a polished roll of metallic lead. To-day, July 26th, the lustre has left the metal, and there is a glistening white deposit at the bottom of the glass, about half an inch deep, which under the microscope, with a  $\frac{1}{4}$  in. Swift's objective, looks very much like epithelium plates, but apparently has no crystalline characters. The supernatant water is perfectly clear. This is what I call the physical examination of the water, and the results observed are characteristic of nearly all soft and many hard waters. Whether the action causing the disintegration of the lead is purely chemical or simply mechanical, or perhaps both, I will leave to the chemist and expert in metals to decide, but that this

action takes place no one can doubt who has studied the subject with simply his unaided eyes and the microscope. What the exact nature of the deposit is, except that it is lead, I do not know, but I get the following results by chemical analysis:—1. On sucking up a small quantity of the deposit with a pipette and adding distilled water I find a feathery looking material very readily held in suspension. It takes some time to settle and when a solution of potassium iodide or potassium bichromate is added no reaction takes place. The deposit is, however, immediately dissolved by hydrochloric acid, and the solution then gives a thick yellow characteristic precipitate with either of the foregoing reagents. 2. On testing the clear supernatant water I find this to contain barely a trace of lead; according to my colour standards about equal to  $\frac{1}{2}$  of a grain of acetate of lead to the gallon.

From the foregoing observations I am driven to conclude, therefore, that there are two dangers in using leaden piping for the service of water: (1) With soft water the lead is taken actually strongly into solution and also exists in a state of minute suspension; (2) with hard water, while not taking as much lead into actual solution, its disintegrating action is quite equal to soft water and its power of holding lead in suspension is greater.

With regard to the action of water on leaden piping I have before me at this moment several specimens of lead piping removed from houses where poisoning existed. These show conclusively that lead is a non-resilient soft metal. Several of these specimens have been subjected to a considerable pressure, having been removed from districts where water is supplied at high pressure. They show irregular dilatations and internally are deeply ploughed, giving evidence of gradual dilatation, and as a result a never-ceasing alteration in the surface of the lining of the pipe for the water to act upon.

To summarise:—1. Is it not imprudent to spoil good water and endanger industry by adding chalk? 2. If the foregoing remarks be correct deductions from facts, should not lead be absolutely and for ever condemned as a means of conveyance for water? 3. Lead, except for its ductility, is the most unsatisfactory metal for water-supply—bursting under frost, dilating and splitting under pressure, and, more than all, poisoning the water. 4. Iron piping is capable of being used everywhere, only requiring rather more time and skill in laying it than lead. It is harmless to the water. I have had for years at my house iron-service pipes, which have been again and again frozen, and have never burst. 5. Considering the fearful amount of human suffering entailed by lead poisoning, would it not be wise, as I suggested in your valuable journal on January 25th, 1890, to erect iron stand-pipes in every street where houses are known to be supplied through long leaden pipes, to give the inhabitants an opportunity of at least pleasing themselves whether they were poisoned or not? 6. And lastly, for the future to prohibit the use *in toto* of lead piping for the service of water for drinking and dietetic purposes.—I am, Sirs, yours faithfully,

July 26th, 1892.

ALFRED SWANN, M.D.

\*\* We may point out, with regard to Dr. Swann's valuable comments, that water is also used in London for both domestic and manufacturing purposes; yet, in spite of this, it is invariably hard, and cases of lead poisoning are of rare occurrence. When soft water is required for the purpose of manufacture—as for the making of steam—it is softened by preliminary treatment. The "chalking" process, after a fair trial, was reported upon favourably and regarded as satisfactory by the Sheffield corporation and also by authorities in other places where this remedy was adopted. Dr. Swann's experiments, however, are not in accordance with these practical results, for he reports that while hard water does not take as much lead into actual solution, yet its disintegrating action is quite equal to soft water and its power of holding lead in suspension is greater.—ED. L.

### THE HUNTERIAN LECTURES.

To the Editors of THE LANCET.

SIRS,—In your last issue you published a letter from Mr. Roger Williams, hardly polite in its tone and bristling with inaccuracies. When appointed to be a Hunterian lecturer nearly a year before, I selected duct cancer as one of

any subjects, the pathology of which disease I have worked at for the past five years, publishing several cases in the Transactions of the Pathological Society. My conclusions have been drawn from such work and my lectures were illustrated by sections from the cases that had come under my notice. Except for a collection of other people's cases illustrated by reprints of their diagrams, published in THE LANCET of April last, I am unaware of any special work done by Mr. Rogor Williams in connexion with this disease. The fact that, having published such a paper, he should now wish to pose as a pioneer in this branch of pathology is very astonishing. My ideas as to classification, which according to his letter I have had the "audacity to appropriate," are given in a paper of my own published some months before,<sup>1</sup> which communication is acknowledged by him. The justification of my statement that Mr. Rogor Williams has grouped together cases of duct papilloma and villous cancer as growths of a perfectly innocent nature is easily proved from his paper. He says: "It will be gathered from the above description that these growths are of a perfectly innocent nature, though often multiple; they have no tendency to local infection, nor do they ever disseminate in the adjacent lymph glands" &c. Now among these cases he includes one of mine which, with some warmth, he maintained at the Pathological Society was not one of villous cancer, as I considered, but innocent in its nature.<sup>2</sup> Following up his opinion he acts on this and draws statistics from it. How correct he has been in his surmise may be seen, since this same case has recurred locally and infected the axillary lymph glands. Further comment on Mr. Williams' frivolous letter is unnecessary; the readers of THE LANCET may easily draw their own conclusions from a perusal of the two papers and from a consideration of the work done by each to try to elucidate this interesting question in breast pathology.

I am, Sirs, yours faithfully,

Lambeth Palace-rd., July 26th, 1892. H. BETHAM ROBINSON.

## "CURES" FOR INEBRIETY.

To the Editors of THE LANCET.

SIRS,—It seems necessary to respect and maintain the professional rule against the use of secret remedies, but many of us do not see our way quite clearly as to the application of this rule. I have always refused to prescribe chlorodyne on the ground (1) that no necessity had been shown for using that nostrum; (2) that its popular use was enslaving and destructive. Here it seemed to me that the professional rule went in furtherance of the public good. But many eminent physicians have regularly prescribed this secret remedy. Are such men liable to be struck off the roll of the Royal College of Physicians? Despite urgent pressure from valued patients I refused to use Koch's tuberculin on the ground (1) that it was a secret remedy, (2) that to inoculate a patient's system with some derivative from tubercle was a proceeding of the gravest character. But, on Professor Lister making a visit of inspection at Berlin and reporting in your columns in favour of this secret remedy, I could no longer refuse to use it for patients who clamoured for it. Was I liable to be struck off the roll of the Members of the Royal College of Physicians for the use of that secret remedy? Recently I was asked by the Committee of the Church Army to watch and report upon some irreclaimable drunkards whom the committee had sent from their rescue department to a home at Putney established by the "Anglo-American Gold-Cure Company, Limited." I visited these men regularly at Putney and watched the performance with as much interest as when, chairman of the Committee on Spiritualism, I watched the performances of the spiritualist professors and others who came before that committee. At this Putney home I have seen, I think, twelve real gutter drunkards—some sent by the Church Army Rescue Department; some sent from the wood-chopping sheds of the Salvation Army Rescue Department; some sent by other benevolent rescue-workers in the slums of London. My rôle has been that of a passive and benevolent but observant spectator. I do not now propose to detail the cases because as yet (three months in all) time has not set its seal upon those results. But I should be dishonest or cowardly if I did not confess that I have been deeply impressed by the

results of the treatment which I have watched upon these poor broken-down brothers and sisters.

The methods of treatment and the remedies used by the "Anglo-American Gold-Cure Company" are admittedly only a modification of those worked out by Dr. Keeley at Dwight. The physician who has worked out these modifications of Dr. Keeley's methods was formerly a helpless inebriate, who was taken by his wife (also a Doctor of Medicine) to Dwight, and who there was cured in three or four weeks. He has been in active, useful work ever since, and is now a very prosperous man. His inspiration, therefore, came from Dwight. On Dr. Keeley's recently visiting London I went into what evidence I could get as to his wonderful clinique of drunkards and morphia-men at Dwight, and I became convinced that "there must be something in it." I received a card from the Church of England Temperance Society for the meeting at the Westminster Town Hall and I went. Dr. Keeley was there. He kindly made my acquaintance as one of the physicians of the Temperance Hospital and I took him over that hospital. He then offered me unrestricted access to the Keeley home near the Marble Arch, and I have watched the results of his treatment and remedies upon the patients there. I have had the privilege of long conversations with Dr. Keeley and I am convinced that he knows more about the handling of drunkards and morphia-men than all the doctors I have ever met before. In fact, upon a subject which has for years worried and sickened me, I feel now that from Dr. Keeley I have obtained new germinal thought. I am convinced also that the results of Dr. Keeley's methods of treatment and remedies are altogether beyond anything that has hitherto been achieved by the profession in regard to the treatment of these narcotics. In point of fact I last week recommended two lady patients who have scarcely been sober for years to go into Dr. Keeley's home. Will my now testifying to these convictions, and my confessing to these acts, make me liable to be struck off the roll of the College of Physicians?

I am, Sirs, your obedient servant,

Dover-street, W., July, 1892.

JAMES EDMUNDS.

To the Editors of THE LANCET.

SIRS,—It is quite true that I reserve for the present the details of my treatment for the crave due to the use of alcohol and narcotic alkaloids, and I submit to any comments which you may think proper to make upon that fact. But in other respects you have been misinformed and I am obliged to ask you to publish my reply.

2. As to my remedies, Dr. Kerr, in his speech (THE LANCET, p. 107), said that my remedy "was very dangerous and was compounded of a number of poisonous intoxicants." Yet a few minutes later Dr. Kerr produced "a careful analysis" (anonymous) which proved that my remedy contained nothing more poisonous than 27.55 per cent. of alcohol. It is not necessary for me to waste time in comment upon such crazy assertions.

3. Dr. Kerr's Society passed a unanimous resolution condemning the use of my remedy for inebriates, on the ground that it contained 27.55 per cent. of alcohol. Could anyone have more completely stultified his Society? My remedy is taken in teaspoonful doses in a wineglassful of water for three weeks only, precisely as any bottle of drops prescribed by any physician in London is taken. But such London drops, instead of containing 27.55 per cent. of alcohol, contain always 57 per cent., and often a great deal more. In point of fact my remedy is a tincture containing just enough alcohol to prevent decomposition. As to Dr. Usher's speech, if he will let us understand exactly what he has to say by a letter in your columns I will answer him. The pink injection does not contain atropine. Dr. Usher is reported as having asserted that three leading physicians from the eastern states visited my institute at Dwight while he was there, and that "six weeks later all their friends received circulars intimating that these gentlemen had been remarkable successes in the cure way." This statement is a sample of others that have been made. It is false. I ought to add that Dr. Usher merely stayed over one train at Dwight, a period of three hours and a half. My chemist is Mr. John R. Oughton. He was in Chicago on that day and Dr. Usher could not have seen him. The young man whom I sent to the treatment hall with Dr. Usher was an Irish bottle-washer. Our pharmacy is a very large one, containing

<sup>1</sup> Transactions of the Pathological Society, vol. xiii., p. 229.

<sup>2</sup> Ibid., vol. xii., p. 221.

a scientific laboratory, and is as perfectly equipped as any chemical laboratory in the United States. Dr. Usher's object in seeing me personally was ostensibly to ascertain if he could buy of me the right to use my remedies in Australia and to open a Keeley Institute there.

4. I do not know what you, Sirs, would have said if I had sent you a letter asking you to come to my lecture at St. James's Hall, and then, in order to get an audience, I had advertised that the Editors of THE LANCET had been invited to speak at the meeting. You would have denounced this as an impudent advertising trick. But this is precisely what Dr. Kerr did with my name. I request Dr. Kerr not again to put my name into his advertisements without having first obtained my permission.

5. As to the deaths which Dr. Kerr parades, they are as inconsequential as his other statements. Without now discussing these particular cases, I have only to demur to his innuendo. The veriest tyro in vital statistics will tell him that half-a-dozen deaths among 70,000 drunkards is an infinitesimal mortality. During the last thirteen years 70,000 drunkards and opium users have (from all parts of the world) come under the care of myself and my assistants. Among that procession of drunkards there have been some 2000 physicians. Of all those patients no one has ever sustained an injury at my hands or as a consequence of my remedies.

6. You have criticised the proceedings of the gentlemen who propose to found institutes in the United Kingdom for the cure of inebriates by means of my remedies and my methods. I have nothing whatever to do with those proceedings. Those proceedings are the acts of Englishmen, and those Englishmen, as I understand, intend to send communications of their own to some of their critics in reference to business matters. What I have to do is to vindicate my own professional position and to answer the charges which have been made against me and against my methods of treating my patients. The only thing which I did was to vindicate an eminent physician in Chicago who was thoroughly conversant with my methods of treatment and with the therapeutical action of my remedies upon inebriates, and to express the opinion that they would act wisely to retain the services of that gentleman as their medical director in England.

I am, Sirs, yours truly,

LESLIE E. KEELEY, M.D., LL.D.

Hotel Victoria, Charing Cross, July 20th, 1892.

\* \* We have omitted the paragraph of our correspondent's letter numbered 1, as it contains language the strength of which would probably in this country be deemed to be of a libellous character. Dr. Keeley's letter in no way removes our objections, and the objections of the profession, to the employment of secret remedies.—ED. L.

## DENTISTRY AND WORKHOUSE CHILDREN.

To the Editors of THE LANCET.

SIRS,—In your issue of July 16th you mentioned under the above heading how the Strand board of guardians had recently appointed a qualified professional dentist to attend the children at their schools at Edmonton, and that the chairman remarked that this was the first appointment of the kind made by any metropolitan or provincial board of guardians, and took credit to the Strand board of guardians for initiating such a necessary and beneficial advance. May I be permitted to say that more than six years ago—viz., April 29th, 1886—the St. Pancras board of guardians on my recommendation appointed a professional qualified dentist practising in London to attend the children in their schools here, which he has continued to do ever since? When pressing this matter on the attention of the board I mentioned how a similar appointment had been made at the North Surrey district schools at Anerley and at the Lambeth schools with the approval of the Local Government Board.

I am, Sirs, yours truly,

J. ADAMS CLARKE, Medical Officer.

St. Pancras Schools, Leavesden, King's Langley, July 25th, 1892.

\* \* Mr. J. Bond, clerk to the Westminster guardians, also writes, saying "the guardians of the Westminster Union appointed a dentist to their school in the year 1886."—ED. L.

## THE CHOLERA IN PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

LAST week I described the conflict of authority existing between the Prefect of Police and the Prefect of the Seine; and how the former authority, taking the bull by the horns, had constituted a Permanent Committee of Hygiene with a staff of medical inspectors. The object of this committee was to centralise the sanitary services with respect especially to disinfection and the removal of patients suffering from contagious diseases to the hospitals. So far so good; but the matter did not rest here. Formerly the public works for the town of Paris were all managed by M. Alphaud. Now that this great administrator is dead the necessity has arisen to divide the various services which he managed and put experts at the head of each department. M. Sauton has submitted to the Municipal Council a project of reorganisation which was discussed on July 21st. Without entering into the detail of the project and the debate I may say that what affects the present epidemic is the fact that the Article No. 2, as amended, was adopted. The following is the text of this Article:—

"Art. II. The Prefect (of the Seine) is invited to constitute, at the Direction of Municipal Affairs, whose action shall be purely administrative, a central service of hygiene and salubrity of dwelling houses, which shall be attached to the services, whether administrative or technical, that relate to the hygiene of the dwellings forming part of the ancient Direction of Works. For this purpose the Director of Municipal Affairs shall be assisted by a General Inspector and a Commission composed of hygienists. The composition of this committee shall be ultimately decided according to the advice of the Municipal Council."

The decree of the Prefect of Police forming a permanent committee of hygiene was issued on July 12th. On July 21st the Municipal Council decided that the Prefect of the Seine shall also have a committee of hygiene and a staff of inspectors &c. Of course some difference must be made between these two committees, and the difference rests on this fact, that the committee under the Prefecture of the Seine will only attend to the interior of houses, and therefore it is called a Central Service of Hygiene and Salubrity for Habitations. No sooner was this matter settled than an Inspector-General of Hygiene and Salubrity of Dwelling Houses was appointed, and Dr. A. J. Martin has been selected to fulfil this office. Certainly it would be difficult to make a better choice. No one has a wider practical experience of hygiene. In England Dr. A. J. Martin is a familiar figure. He was the Commissioner of the French Government for the French Section of the Health Exhibition held at South Kensington and was prominent at the recent International Congress of Hygiene which met in London.

At first sight it would appear as if the appointment of two committees, one under each of the rival Prefectures, would only add to the confusion actually prevailing. There is, nevertheless, every reason to hope that this will not be the case. The other day I had a good illustration of the manner in which the arrangement will work. There may be antagonism between the two Prefectures; there is no antagonism between the well-known and prominent medical men and sanitary reformers who are battling for the cause of hygiene in France. Thus, when I went to congratulate Dr. A. J. Martin on his appointment, I found he was expecting a visit from Dr. Dujardin-Beaumetz. Now Dr. Dujardin-Beaumetz is a member of the Council of Hygiene attached to the Prefecture of Police. When something had to be done in conjunction with the Prefecture of the Seine, a clerk of the Prefecture of Police was told off to communicate the fact to a clerk of the Prefecture of the Seine. These clerks, it must be borne in mind, lead a most tedious, monotonous life. For want of something better to occupy their minds they develop a sort of patriotism in favour of their particular office or branch of the administration. This engenders extraordinary susceptibilities; and just as courtiers used to quarrel as to who should walk first in a royal procession, so the clerks of the Prefecture of Police quarrelled with the clerks of the Prefecture of the Seine as to who should fulfil certain functions. Such squabbles relieve the monotony of the bureaucratic life; but, as I mentioned last week, they have been so acute that it is supposed a life may have been lost because it was below the dignity of one adminis-

eration to ask for an ambulance waggon from the other administration. Now, what do we see? Simply this, that instead of giving directions to clerks to write letters, dealing often with technical matters of sanitation which they do not understand, Dr. Dujardin-Beaumez calls on Dr. A. J. Martin to settle amicably—for they are the best of friends and thoroughly understand each other—what would probably have occasioned the outbreak of a fearful paper warfare between the clerks of the Prefecture of Police and the clerks of the Prefecture of the Seine. The fact that the two administrations are now represented by medical men and hygienists who are friends will do more than any amount of legislation to make matters work smoothly and efficaciously.

On inquiring from Dr. A. J. Martin what would be the nature of his new functions, he naturally expressed some ignorance as to an office which had only been created on the previous afternoon. He will have to deal with domestic sanitation, and this is much more neglected in France than public hygiene. Dr. Martin's ambition would be, in the course of time, to establish the sanitary record of every house in Paris. This has already been partially done, and done admirably, by M. Louis Masson, chief sanitary inspector of Paris. But M. Masson derives his authority from the Direction of Sewers, and only dealt with drainage. If any person is about to purchase a house or take a long lease of a house in Paris, I should advise him to go to the office, 6, Avenue Victoria, and ask to see the inspector's report on the house in question. The method of tabulating is so perfect that there will be no difficulty in finding this record, and the intending tenant or purchaser will know, from a disinterested public office, how the house he proposes to take is drained. But it has not been M. Masson's business to record how the house is built, whether the walls are damp or of the proper thickness, whether the rooms are well ventilated, or whether there are any unwholesome trades carried on in the dwellings. It is not one phase, but every phase, of the sanitation of dwellings which Dr. Martin has to watch. He will also have to see to the creation of a staff of competent inspectors to help in the work.

For the present the chief business is to secure the prompt and efficacious disinfection of all premises where cases of cholera occur. On Friday, the 22nd inst., the very day on which the new committee was created, seven premises within Paris had to be disinfected in consequence of cholera, and the mortality still continues to be very high. I have already described how the Prefecture of Police has a staff of disinfectors and the Prefecture of the Seine the disinfecting stoves. Now the Prefecture of the Seine has also created a staff of disinfectors, so that the entire operation can be done by the one authority. Better than this, the Prefecture of the Seine insists on doing the whole of the work, even though the agents of the Prefecture of Police have previously done half the work. Thus, for instance, a case of cholera occurs. The friends of the patient send to the Prefecture of Police and ask to have the premises disinfected. Disinfectors organised by the Prefect of Police come and disinfect the room. It is then thought necessary to send the bedding to be disinfected in the stove. For this an application must be made to the Prefecture of the Seine, which authority at once despatches a cart and a staff of disinfectors. Before removing the bedding they disinfect the room. They are told that the agents of the Prefecture of Police have already disinfected the room; but the agents of the Prefecture of the Seine reply that that does not concern them; they will not be responsible for what others do, and they have formal orders not to remove anything from a room without having themselves first disinfected it. Thus the work is done a second time. I think Dr. Dujardin-Beaumez and Dr. Martin, when they have a friendly chat over the matter, will contrive something more practical than this.

Paris, July 26th.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Owens College.*

It is announced that Mr. W. H. Perkin, Jun., F.R.S., hitherto of the Heriot-Watt College, Edinburgh, has been appointed successor to the late Professor Schorlemmer in the chair of Organic Chemistry at Owens College.

### *The Infirmary and Owens College.*

The struggle between these two institutions has entered on a further stage. Last week the board of management of the Royal Infirmary met a committee of the memorialists, i.e., the signatories to the memorial deprecating any extension of building on the present infirmary site for these reasons—*viz.*, that the open ground now existing should be preserved for the general good of the town; that the infirmary area taken as a whole would only be large enough to give room for about 450 beds, a number probably considerably below that which will be needed in the near future to supply the requirements of Manchester; that a site in every way suitable for the building of a hospital, which shall be capable of being enlarged as occasion arises, has been offered in the shape of the Whitworth estate; and, lastly, that any addition to the present building would only tend to prolong the existence of an obsolete hospital structure. The majority of the memorialists, however, propose that for the present a hospital of only 120 beds be erected on the Whitworth estate, and that the present infirmary shall continue as before. The ultimate intention appears to be to enlarge the new hospital, the old one remaining as a receiving house for urgent cases of accident or illness arising in the centre of the town or brought there by railway. Teaching would then be carried on chiefly at the new hospital, for which Owens College would appoint professors of clinical medicine and surgery with hospital beds. The present infirmary board had prepared plans for additions to the present hospital amounting to 120 beds. The aforesaid meeting had no satisfactory result, each side standing its own ground, though it should be mentioned that the infirmary was, and has for some time past been, prepared, in the event of the present building being added to, to offer beds to professors of clinical medicine and surgery of the College's appointing, on condition that these gentlemen would conform to the rules at present laid down for members of the infirmary honorary staff. To-day a general meeting of the trustees took place, at which the proposals of the Infirmary Board were defeated by a close, though not a very large, majority, an amendment, practically negating the infirmary extension proposal, being carried. The Infirmary Board have demanded a poll of the trustees on the question and the result will be looked for with the greatest interest. There can be no doubt that upon this final decision of the trustees by poll depends the future of the infirmary as a teaching hospital.

### *Insanitary Dwellings.*

A curious prosecution took place on the 22nd inst., when about forty poor people were summoned at the city police-court for refusing to leave dwellings which had been condemned as being too unhealthy for human habitation. Notice to quit had in all cases been given long ago and it was proved that some of the tenants, after having left, had returned and others had been supplanted by newcomers. The corporation are making the greatest efforts to abolish all unhealthy dwellings and their task seems to be a difficult one, not only from the objections of landlords but from those of tenants of this class. Small fines were imposed in the majority of cases and the tenants promised to leave for good.

Manchester, July 27th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *The Will of the late Dr. G. Y. Heath of Newcastle: Munificent Bequests.*

THE will of the late Dr. G. Y. Heath, concerning which there has been so much speculation, has been at last proved. It will be seen that I have been correct in the main as to Dr. Heath's charitable and scientific bequests. Dr. Heath left personalty of the gross value of £89,641 5s. 5d., net value £88,401. He bequeathed to his three executors £1000 each, to one of whom, being his nephew, he left a further sum of £8000; to Miss Lily Everett, £2000; to his brother, Mr. Robert Heath of Heppersley, Cheshire, £5000; to his niece, Mrs. Rose of New Zealand, £1000; to his cousin, Miss Sothern, £1000; to Mrs. Francis Casson, £1000; to Miss Mary Jane Spenceley, £10,000 and his plate, pictures, furniture and household effects; to the Royal Infirmary in Newcastle-on-Tyne, £5000 (afterwards altered to £8000), towards building, completing, or furnishing a new infirmary;

and to the Northern Counties Home for Nurses £5000 (afterwards altered to £2000). He bequeathed to the Durham University College of Medicine, Newcastle, £5000 to found a chair or professorship of Comparative Pathology; to the Durham University College of Medicine at Newcastle £10,000, to provide residences for students; to the Kepier Grammar School at Houghton-le-Spring £5000, for scholarships for students of medicine at Durham University College at Newcastle-on-Tyne; £4000 in trust to Mr. Page and Dr. Arnison, to found a scholarship in the Newcastle College of Medicine, the income to be paid for two years to the author of the best essay on some surgical subject. He bequeathed to his pupil, Mr. Douglas, £100, and the executors are to expend £100 a year in completing his education. The testator left all the residue of his property in trust for Miss Mary Jane Spenceley. By an order of Court the bequests to the Infirmary and the Northern Counties Nurses' Home are to stand at £5000 each, as they appeared in the will before the alterations. It will be seen that the charitable and scientific bequests to Newcastle and district amount to £34,000.

#### *Stockton and Middlesbrough.*

At a late meeting of the Middlesbrough Fever Hospital Committee it was reported that the number of small-pox cases being treated at the hospital was nine, and at a meeting of the Tees sanitary authority it was stated that 141 vessels had been inspected during the month; all were in good order and free from infectious disease. The notices to captains mentioned in a former letter had been printed in various languages warning them not to send any sick ashore until they had been seen and sanction had been given by a medical man.—At a meeting of the Stockton and Middlesbrough Water Board, held last week, it was reported that the Hury reservoir contained water to a depth of 75ft. 6in., or within 14ft. of full depth. It could have been fully filled but for some finishing work which had to be done to the dams. The tender for an aqueduct across the Tees had been accepted.—The annual demonstration of the Stockton friendly and trades societies has been held on behalf of the town's hospital and has been very successful as regards numbers and the amount collected. The mayor, in an energetic speech, said that during the year two-thirds of the income of the institution had come from the pockets of the working classes, and very properly too, since it had been established, kept up and looked after chiefly on behalf of and by the working classes.—Another paraffin lamp fatality has taken place at Middlesbrough, where a child one year and ten months old was so badly injured by the breaking of a lamp that it died four hours and a half after admission to the hospital.—The South Shields guardians have decided to ask the sanction of the Local Government Board to the appointment of an assistant medical officer at a salary of thirty guineas per annum.

#### *Carlisle.*

A curious case was raised at Carlisle the other day as to the Inspector of Nuisances. It was shown that if the inspector always used a uniform he might convey about with him the germs of disease. After much discussion it was arranged that the inspector should wear what might be called a "dress suit" on certain occasions, but that when dealing with infectious cases he could use an old suit to be kept for this purpose.

#### *Death from an Illegal Operation at Kirkby Stephen.*

An adjourned inquest was held on Friday last at Kirkby Stephen on the body of a female domestic servant who died on the previous Monday under circumstances which were at first supposed to point to poisoning. The jury, however, found that death had resulted from wounds caused by some instrument, but by whom inflicted there was no evidence to show. We shall probably hear of this case again.

#### *The Weardale Guardians and their Medical Officer.*

At a late meeting of the Weardale guardians they discussed the application of Mr. Bourne for a pension after a service of forty-four years. It was asked to rescind the motion of censure passed upon him for absence from duty one day whilst acting at a poll booth. He claimed it on the ground of the day being one of the four days' holiday he was allowed, but the motion to rescind this unpleasant censure was not carried. The guardians, however, in all fairness, should remember that their surgeon had served them forty-four years before the elections.

At the last meeting of the North of England Branch of

the British Medical Association Mr. Blandford was appointed president-elect, and it was decided that the annual meeting should take place at Stockton.

Newcastle-on-Tyne, July 27th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

#### *The Health of Aberdeen: Town and County.*

THE return for last week for the town was: measles 29, scarlet fever 9, diphtheria 1, typhoid fever 1, typhus fever 1, whooping cough 8, erysipelas 3—total cases 52, being a decrease of 11 as compared with the previous week. For the county: scarlet fever 4, erysipelas 1—total cases 5.

#### *Public Health Prosecutions.*

Two householders in Torry, the fishing quarter of Aberdeen, were convicted last week of having wilfully concealed from the medical officer of health and the sanitary staff the presence of cases of measles in their houses and were fined 5s. each with costs. These cases were brought prominently before the public as a warning, owing to the rapid spread of measles in the locality and the successful attempts of the people to frustrate the efforts of the sanitary staff to eradicate the disease.

#### *Slander Case against a Medical Man.*

In the Scotch Court of Session, before the Lord President, an action brought by Dr. John Barclay, Banff, for slander was heard and decided last week. The defender was Mr. Robert Duncan, merchant, Banff, factor of the Chalmers Hospital, Banff. The statement complained of was that pursuer had taken liberties with nurses in Chalmers Hospital, Banff, of which he was at the time of the scandal a medical officer. The evidence went to show that Mr. Duncan had been the means of spreading the report complained of. The defendant, while admitting that the charge against Dr. Barclay was utterly groundless, maintained that the report had not originated with him. After evidence had been led, the Lord President charged the jury, asking them to dismiss from their minds all doubts as to the innocence of the pursuer, for all were agreed that the pursuer was absolutely innocent and blameless. What they had to decide was whether or not the defendant had issued the slander. The jury returned a unanimous verdict for the pursuer, and assessed the damages at £200.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

#### *Health of Dublin.*

DURING the five weeks ending July 2nd the deaths from the seven principal zymotic diseases were in the ratio of 4.16 per 1000. These included 117 from measles, 15 from whooping-cough and 3 from typhoid fever. During the month the admissions of measles patients into hospitals declined considerably, while those of typhoid fever cases increased largely. The death-rate was very high, higher than in any corresponding period during the previous ten years. The present epidemic of measles has caused up to June 30th no less than 390 deaths.

#### *Poor-Law Medical Officers' Association.*

At a meeting of County Cavan Poor-Law Medical Officers' Association, held recently, the following resolutions were adopted unanimously: "That Dr. Ryan of Bailieborough be requested by this Association to approach the future M.P.'s for the county, Messrs. Young and Knox, with a view of obtaining their Parliamentary influence on behalf of Poor-law medical officers of Ireland." "That in the opinion of this Association the Poor-law medical officers of Ireland are entitled to at least one month's annual holiday, irrespective of sick leave, their substitutes to be paid at the public expense; and that in the opinion of this Association Poor-law medical officers' salaries should be progressive, as in all other official and semi-official departments."

#### *British Institute of Public Health.*

The annual meeting will take place this year in Dublin on Aug. 17th and two following days, under the presidency of Sir Charles Cameron, medical officer of health for Dublin

The Vice-Presidents include the Lord Mayor of Dublin, the provincial mayors, the Presidents of the Colleges of Physicians and Surgeons, Sir. J. Banks, K.C.B., Sir George Porter, Bart.; Dr. Kidd, President Royal Academy of Medicine &c. The inaugural address will be delivered by the President at the Royal College of Surgeons on Wednesday morning, Aug. 17th, and the same evening the members will be entertained at dinner at the Lucan Hydro-pathic Hotel. The following day the annual dinner will take place at the Royal Marine Hotel, Kingstown, while on the third day of the meeting the Chairman of the Dublin Waterworks Committee (Sir Henry Cochrane) will entertain the members of the institute at the Varty Works at Roundwood. Among the papers to be read at the Congress will be one entitled "The Etiology of Typhoid Fever," which must prove of considerable interest to the citizens of Dublin, while a special discussion will take place on the Notification of Infectious Diseases. The honorary secretary to the meeting is Mr. Edgar Flinn, F.R.C.S.I., of Kingstown.

#### *Health of Soldiers in Ireland.*

The report of the Army Medical Department for 1890 has been issued to the public, but the unnecessary delay in its publication minimises considerably its value. The average strength in 1890 in Ireland was 24,857, of whom 18,607 were admitted to hospital, 377 were invalided, 1022 were constantly sick and 127 died.

#### *Belfast Hospital for Diseases of the Skin.*

From the report read at the annual meeting of the friends of this charity, held on July 19th, I learn that 1166 patients were treated during the past year, of whom thirty-two were received into the hospital. If the funds were larger more intern cases could be treated, but there has been a decrease in the subscriptions during the year and no new ones are coming in. The income for the year is £308 16s. 10d., and the expenditure £362 8s. 3d. Attention was drawn by some of the speakers to the fact that one-third of the patients came from the country, and a suggestion was thrown out that local secretaries might be appointed throughout Ulster and that if a ladies' committee were formed more interest in the institution would be taken by the general public.

The Lord Chancellor has appointed Mr. Richard Browne Carey, L.R.C.P.I. &c., of Borris, County Carlow, to the Commission of the Peace for County Carlow.

Dublin, July 27th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Cholera Epidemic.*

THE outbreak in the suburbs of Paris of cholera, or, to adopt the official nomenclature, "choleraic diarrhoea," is reported to be declining in intensity. Such is the report furnished on Monday last by the Commission of Inquiry appointed by the Comité Consultatif d'Hygiène Publique—a commission composed of Professor Proust, MM. Netter, Ogier and Thoinot. These gentlemen assert that the army and the city of Paris (!) remain free from the disease. I have already informed your readers that the examination by M. Netter of the excreta of patients who had succumbed to the disease in several Paris hospitals had revealed the presence of Koch's comma bacillus. M. Netter now (Société Médicale des Hôpitaux, 15th inst.) sums up the results of the bacteriological inquiries he has made on this subject. After recalling the fact that the discovery of the bacillus was first made by M. Léon, Professor Peter's chef de clinique, who found the cholera micro-organism in the intestinal contents of the body of a fireman of Grenelle who died in less than twelve hours after the onset of his illness, M. Netter stated that his own researches extended to forty-nine cases, in twenty-nine of which the *bacille virgule*, or comma bacillus, was discovered, that germ being absent in the twenty others. In seventeen of the twenty-nine cases the bacillus was found in the stools passed during life or in portions of mucus collected from the clothing, bedding or the margins of the anus. In three cases the intestinal contents were examined after death, while in the remaining nine cases both methods of examination were had recourse to. Not once was the bacillus found in the blood, but in one instance its presence was discovered in a patch of bronchopneumonia, associated, however, with the streptococcus

pyogenes. Although the suburban comma bacillus of 1892 exhibits certain differences of behaviour in culture experiments from the specimens preserved since 1883 (Calcutta) and 1884 (Toulon and Paris), these differences disappeared when the comparison was made between it and a specimen collected this year at Cochinchina. In the twenty cases characterised by the absence of the cholera bacillus, the bacterium coli was constantly present. Of these twenty patients, all treated in Paris, ten contracted the malady in the suburbs and ten within the walls of Paris. The symptoms were those of true cholera—diarrhoea, with often rice-water stools, vomiting, cramps, subnormal temperature, oliguria or even total anuria, feebleness of voice &c. Six of these patients died. These negative bacteriological results are only a repetition of what was experienced in 1888, 1889, 1890 and 1891. M. Netter states categorically that cases purely Parisian can be distinguished from suburban cases by bacteriological examination, the micro-organism present in the first class of cases being the bacterium coli, and in the other the true cholera bacillus. He further clearly states that, putting aside actual contagion, Seine water is the mode of conveyance of the germs in the infected suburbs, all of which are situated down stream—i.e., below Paris. M. Chantemesse confirms the assertions of M. Netter. Professor Dieulafoy informs us that between May 25th and June 2nd he has had four cases to treat at the Hôpital Necker. Since the latter date all cases have been isolated and placed under Professor Peter's care. Of the four cases two were of a light type and recovered in a few days. In their stools only the bacterium coli commune was discovered. The other two cases were much more serious. In one instance a man of twenty-seven years, living in the fourth arrondissement, which was then under the *eau-de-Seine régime*, was seized on May 26th with all the characteristic symptoms of cholera. On May 30th he was well again. The other patient was a woman aged forty-nine years, an inhabitant of Billancourt. She died in fifty hours. The stools of both these patients contained the true cholera bacillus. I am of opinion that the discovery of the comma bacillus in the stools of Professor Dieulafoy's fourth arrondissement patient effectually refutes M. Netter's contention that *l'épidémie cholériforme* is peculiar to Paris, whilst true cholera is strictly limited to the suburbs.

#### *The Dangers of Ice.*

Immense quantities of ice are, it is needless to say, consumed during the summer months in this city of cafés. The question of its purity has often been raised, most people, however, swallowing it in perfect faith. That some portion at least of the ice supplied is not above suspicion from a sanitary point of view is proved by the recent action of the Conseil d'Hygiène de la Seine in forbidding the extraction of that product from an ice pond situated close to the river Seine. Another resolution passed unanimously by the Council was that a service of superintendence, with if necessary an analytical branch, be instituted with a view of controlling the quality of ice sold in Paris. It was also decided to request the Prefect of Police to keep a vigilant eye on the manufacturers of artificial table waters, as also *ourafes frappées* (decanter containing a lump of ice), and to inquire as to the origin and quality of the water employed in the fabrication of these articles.

#### *M. Pasteur's Health.*

All the scientific world will rejoice to hear that this veteran *savant* was present at last Monday's meeting of the Académie des Sciences, of which body he is such a distinguished ornament. He appeared in excellent health and stated that the numerous deadly diseases from which he is supposed to have suffered have existed only in the fertile imaginations of enterprising journalists. Whilst being loud in his praise of Garches, where his château is situated, he could not refrain from regretting his temporary absence from his beloved laboratory.

Paris, July 27th.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

#### *The Cholera.*

THE authorities in the eastern provinces of Prussia are earnestly providing for the eventuality of cholera. A Königsberg paper stated the other day that Professor Koch had arrived there on the 19th inst., and at once proceeded *vis*

Eydtkuhnen to the cholera districts in Russia, taking several chests full of disinfectants with him. This news, however, was incorrect. The following letter from a medical man to the *Vassische Zeitung* (which I abridge) may perhaps interest your readers at this time: "The measures for the prevention of cholera consist in general hygienic precautions, the provision of hospital accommodation and medical help, and the earliest possible recognition and isolation of the disease. The germs of cholera are transferred in the main by the evacuations of the bowels of cholera patients. The certain diagnosis of cholera depends on the finding of cholera bacilli in the evacuations and their cultivation in nutritive solutions. It is therefore of paramount importance that when cholera breaks out there should be a medical man on the spot familiar with bacteriological methods. To a certain degree the Medical Administration has provided for this. After Professor Koch's return from his journey to Egypt and India, during which he discovered the germ of cholera, courses of instruction were instituted in the Imperial Office of Health in Berlin, in which medical officials from the frontier districts were taught the bacteriological methods of recognising cholera. Other medical officials have since had occasion to acquire the necessary knowledge of these matters. It is also not to be forgotten that, now that bacteriology has acquired special importance, and that hygienic institutes have been established in most of the universities, the knowledge of bacteriological methods has spread widely among practitioners. At the same time, however, there is no doubt that, in the event of an outbreak of cholera in Germany, all these bacteriological experts will not suffice for the necessary investigations, especially as the treatment of their patients will leave them no time. It is therefore desirable that the Medical Administration should inquire among the younger medical men whether they are willing in such an event to go to the frontier districts to help. Should, as is likely, the number of volunteers prove inadequate, courses of instruction in the investigation of cholera evacuations must at once be arranged."

*The Report of the Berlin International Medical Congress.*

Immediately after the close of the Tenth International Medical Congress, which met in Berlin in August, 1892, the preparation of the official report began, and it is now at last complete in five stately volumes, published by Hirschwald of Berlin, to which a general index in three languages is added. The first volume contains a history of the Congress, including the discourses of Bouchard, Axel, Key, Lister, Koch, Cantani, Wood, Meynert, Stokvis, and Virchow; the second, the discussions in the sections of anatomy, physiology, physiological chemistry, pathology, pathological anatomy, pharmacology, internal medicine and the diseases of children; the third, those in the sections of surgery, orthopædics and gynaecology; the fourth, those in the sections of neurology and mental disease; and the fifth, those in the sections of dentistry, hygiene, railway hygiene, medical geography and climatology, medical jurisprudence and military hygiene.

*Miscellaneous Items.*

Dr. du Mesnil de Rochemont, private lecturer in the University of Würzburg, has been appointed Head of the Medical Department of the City Hospital in Altona.

Dr. Georg Hoppe-Seyler, private lecturer on Internal Medicine in the University of Kiel, has been appointed Professor there.

The honorary title of Professor has been conferred on Dr. Moritz Schmidt of Frankfort-on-the-Main, one of the oldest and most eminent of the German laryngologists.

Dr. von Bayer, Professor of Chemistry, has been elected Rector of the University of Munich for 1892-93.

Berlin, July 26th.

## Obituary.

### FREDERICK LE GROS CLARK, F.R.C.S., F.R.S.

A WELL-KNOWN and striking figure has just passed away from us in Mr. Frederick Le Gros Clark, a former President of the Royal College of Surgeons, and Surgeon to St. Thomas's Hospital. Mr. Clark was born in Mincing-lane in 1811, and was educated in Iron Acton, in Gloucestershire. At the age of sixteen he commenced his professional studies as an

articled pupil under Mr. Travers, then senior surgeon to St. Thomas's Hospital; and three years later, at the close of his school curriculum, he obtained the Cheselden medal for proficiency in Surgery and Surgical Anatomy. After spending a session in Dublin he became an assistant demonstrator in the University there, and subsequently enlarged his sphere of experience in Paris, Berlin, Göttingen, and Edinburgh. In 1839 he was appointed assistant surgeon to his Alma Mater, in which post and as lecturer on Descriptive and Surgical Anatomy he remained until the death of Mr. Tyrrell in 1853, when he was promoted to fill the vacant place on the surgical staff. He next succeeded Mr. John Flint South in the chair of Surgery, and continued to lecture until, after thirty years of office, he terminated his active connexion with the hospital in 1873, retiring with the honorary title of consulting surgeon. His relation to the College of Surgeons was no less distinguished. He became a Member of the Council in 1864, and as Hunterian Professor of Surgery and Pathology delivered a course on "Surgical Diagnosis, especially in reference to Visceral Lesions," in the summers of 1867 and 1868. In 1872 he was elected a Vice-President, and in 1874 was chosen for the crowning office of President, delivering the Hunterian Oration from the presidential chair in the following year. He held in addition several important surgical appointments, and was also a prominent member of the Salters' Company, in which he twice filled the office of Master. As an author he was well known by his "Anatomy and Physiology of the Nervous System," published as early as 1836; his translation of Dupuytren's "Diseases and Injuries of the Bones"; his "Outlines of Surgery," which passed through a second edition in the hands of Mr. Wagstaffe in 1870; his Hunterian Lectures; and by numerous other works, all marked by wide research and a clear and polished diction. After his retirement from practice he built for himself a charming retreat at Sevenoaks, where he spent the rest of his days. He retained his activity and displayed a lively interest in the advance of his profession almost to the last. His strength began to fail about eighteen months ago, but he continued to enjoy the society of his friends and to make occasional journeys to town until the middle of June, when he was forced to take to his bed. He died on July 19th, and was buried at Riverhead on the 23rd amidst innumerable demonstrations of respect from his private friends and the public bodies with which he had been associated.

Mr. Clark was a splendid representative of the educated surgeons of the older school. A man of great general culture, versed in all the professional lore that the home and Continental schools of his time could teach, and amongst surgeons an accomplished operator in the days when the operator required faculties that modern science has rendered unessential. His personality was peculiarly attractive. All who knew him can easily recall the tall, strong, upright figure that retained its symmetry to the end, the clearly cut aristocratic features that only grew more handsome with the advance of years, and the dignified courtesy of manner that so perfectly harmonised with the stately physique; but it was not given to all to know the simplicity and gentle kindness of nature masked by the rather stern lines that early sorrow had graven on his face. His friends and patients always learned to love and trust him; and there are yet living many of his old pupils who have reason to cherish a grateful and affectionate recollection of the warm sympathy with which he continued to watch and aid their progress. He was a bold and successful surgeon of the school of Travers and Astley Cooper and a true gentleman after the bygone type that fiction has preserved for us in Sir Roger de Coverley and Colonel Newcome.

### J. HARRINGTON DOUTY, M.R.C.S., L.S.A.

WE regret to have to record the death of Mr. J. Harrington Douty, medical superintendent of the Berks County Asylum. Mr. Douty was in his usual health until July 5th, when he was suddenly taken ill, and died on July 12th. He was born in 1858 and received his medical education at the Middlesex Hospital, where he distinguished himself by obtaining the Senior Entrance and the Senior Broderip Scholarships. He qualified in 1881, after which he held the post of house physician at the Middlesex Hospital for one year. In 1882 he was appointed assistant medical officer to the Worcester County and City Asylum at Powick and in 1887 medical superintendent to the Berks County Asylum at Moulsoford. The zeal and devotion which characterised the whole of his

work in these appointments had procured for him the highest commendation of the various boards of managers under whom he held office. Mr. Douty was the author of several valuable contributions to the medical journals bearing on mental science. His able administration of the Berks County Asylum, no less than his kindness of heart and manner, had earned for him the respect and friendship of all with whom he came in contact, and his untimely death at the early age of thirty-four will be deeply regretted by everyone who knew him.

#### WILLIAM EDWARD BALKWILL, M.R.C.S., L.S.A.

MR. W. E. BALKWILL was born at Kingsbridge, Devon, on June 14th, 1849, being the eldest son of W. H. Balkwill, Esq., and a descendant of the celebrated George Fox. He was educated at the Kingsbridge Grammar School and at Amersham Hall School. His medical education was received at St. Bartholomew's Hospital, where he displayed great industry and marked enthusiasm, and was the leader of a large group of earnest and successful students. After obtaining his qualification to practise he was appointed house surgeon at the Royal Orthopaedic Hospital, and filled that office from 1872 to 1875. A vacancy then occurring on the honorary staff, Mr. Balkwill was elected to fill it, and he started in practice in Old Cavendish-street and devoted himself entirely to this department of surgery. He was very successful in it; he combined operative skill and mechanical ingenuity with great devotion and kindness to his patients, all of whom became his friends; and his modesty was as pronounced as his kindness of heart. Mr. Balkwill took great interest in athletic performances of all kinds, and was a recognised authority on such subjects. He was an admirable shot and generally spent his holidays on the moors. In the spring of 1891 he had a serious attack of influenza, and in January, 1892, he was again seized with the prevailing disorder. He appeared, however, to have regained his usual health, but on Sunday, July 10th, he was suddenly smitten down with cerebral hæmorrhage and passed quietly away on the morning of July 11th.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An ordinary meeting of the Comitia of the Royal College of Physicians was held on Thursday, the 28th inst., Sir Andrew Clark, President, in the chair. Dr. Donald William Charles Hood and Dr. John Ebenezer Ranking, who were elected Fellows in April last, were admitted. Dr. Edward Alfred Birch, being resident in India, was admitted a Fellow *in absentia*. The following gentlemen, having passed the required examination, were admitted as Members:—John Rose Bradford, M.D. Lond., Charles Petre Lovell, M.B. Oxford, Frederick John McCann, M.B. Edin., Solomon Charles Smith, M.D. Durham, Neville Thorold Wood, L.R.C.P. Licences to practise were granted to 134 candidates, and diplomas in public health to eighteen practitioners. A copy of the Japanese Pharmacopœia was received from the Foreign Office, as was also a case of drugs from Chefoo, the latter being referred to Dr. Mitchell Bruce and Dr. Hale White for report. An application from the Hospital for Women at Leeds for recognition as a place of instruction in gynaecology was referred to the committee of management, and a copy of the arms of the College was sent to the Yorkshire College at Leeds for the decoration of the hall of that College. Letters of thanks for copies of Harvey's Lectures *in fac-simile* were received from Dr. Brouardel, Professor Corradi, and Herr Joseph Körösi. An important report from the 'Censors' Board respecting the sale or transfer of a practice and the transfer of patients for a pecuniary consideration from a Member to a Fellow was read, and a resolution was unanimously adopted to the effect that such a transaction was contrary to the traditions of the College and derogatory to the position of a physician. The resolution will be sent to every Fellow and Member of the College. A report was received from the Fever Hospitals' Committee recommending that students should visit the small-pox hospital ships for a period of two weeks, but that this attendance should not be compulsory, and that the disciplinary measures should be similar to those in force at the fever hospitals. The College seal was set

to the lease from the Queen, as Duchess of Lancaster, of the ground in the Savoy, on which the buildings of the Royal Colleges stand. The Censors, Examiners, and other College officers were elected. The usual reports of the Examiners, of the Finance Committee, of the Library Committee and of the Curators of the Museum were read and adopted. The West Riding Lunatic Asylum was recognised for the attendance of students, and a list of the workers in the laboratories and of the work on which they were engaged was also presented. A proposal to establish a sinking fund to cover any liabilities which may arise on the termination of the lease in 1984 of the site on which the Examination Hall and the Laboratories are erected was referred to the Finance Committee. The College will be closed during the next two months for decoration, repairs and the installation of the electric light.

#### MEDICAL TRIALS.

##### HIGH COURT OF JUSTICE, QUEEN'S BENCH DIVISION. (BEFORE MR. JUSTICE WRIGHT.)

EX PARTE ALLINSON—IN THE MATTER OF AN ORDER OF THE GENERAL MEDICAL COUNCIL.

In this case the General Medical Council, under the Medical Act of 1858, section 29, had made an order to erase from the register the name of one Allinson for certain conduct of his, and he had obtained *ex parte* an order for an injunction to restrain them from publishing it in their proceedings.

Mr. Reid, Q.C. (with Mr. Muir Mackenzie), now moved, on the part of the General Medical Council, to discharge the injunction, which, he said, had been obtained *ex parte* and on statements which were contradicted and went to the merits of the case, which had been dealt with by the General Medical Council under their statutory authority, which had been recognised in several cases, one before the Court of Appeal ("*In re Allbutt*," 23 Q.B.D., 40; "*Ex parte Leeson*," 48 Ch. Div., 386; "*In re Partridge*," 8 *The Times* Legal Reports, 463). In these cases it had been settled that if the Medical Council acted honestly, then proceedings within their jurisdiction would not be interfered with. Mr. Justice Gainsford Bruce: They are the only authority to determine whether a man's name shall be erased from the register?—Yes, Mr. Justice Wright: We cannot try the case, which will be tried in the action, and if the plaintiff succeeds, then perhaps he may obtain an injunction, but we cannot try the case by anticipation.—The injunction would be very inconvenient, as it would prevent the half-yearly publication of the minutes of the Council's proceedings, which are of great advantage to the profession. In Leeson's case there was a hearing of the action. Mr. Justice Wright: This is an *ex parte* application before the hearing, which is quite different.—Just so. This is an application for an interim injunction.

Mr. H. S. Young appeared on the part of the applicant in support of the injunction. The judges, he said, who granted it read the advertisements. The erasure of the applicant's name prevents him from practising. Mr. Justice Wright: We cannot restore the name to the register; it is already erased.—It is not erased from the printed register. Mr. Justice Gainsford Bruce: The register is legal evidence.—Yes, and in the printed registers his name is not erased. Mr. Justice Wright: It cannot be erased from the thousands of copies in circulation, but if the question arises it will be tried by reference to the original register. Mr. Reid said it was erased there. Then the publication of the erasure there will prejudice the applicant. Mr. Justice Wright: It ought to be published; his name is erased from the register; otherwise he will be enabled to practise under false pretences.—It is only erased from the written register. Mr. Justice Wright: That is the register, though printed copies may be evidence.—If this injunction is not retained the plaintiff may be prejudiced and prevented from practising. Mr. Justice Wright: Your plea apparently is that if we continue the injunction he may continue to practise.—Yes, if the injunction continues he will be a registered medical practitioner. Mr. Justice Wright: Suppose we think otherwise and that he is not a registered medical practitioner until his name is restored, what substance will there be in your application?—It will prevent further publication of the fact. Mr. Justice Wright: Do you seriously maintain that, assuming we hold he is no longer a registered medical practitioner, we are to compel the Council to publish that he is?—No, certainly; that cannot be asked. The Council ought not to continue to publish the erasure. But the hearing cannot come on before the Long Vacation and unless the injunction is continued the applicant will be seriously injured.

The Court, however, discharged the injunction. Mr. Justice Wright said the continuance of the injunction was evidently pressed for under the impression that the effect would be to enable the applicant to practise, but that was quite an erroneous notion and, therefore, there was no real or substantial advantage in it. No one can suppose that we should order the Council, before the hearing of the case, to put back his name on the register from which it has been erased, so as to produce a false impression that he is still a registered practitioner when in truth he is not. If the plaintiff shall succeed in his action there will be time enough to apply for an injunction to prevent publication. At present the injunction must be dissolved.

Mr. Justice Gainsford Bruce concurred. It would require, he said, a strong case to justify such an injunction. The General Medical Council were intrusted by the Legislature with the duty of determining whether a name should be erased from the register. And the injunction would not restore the name already erased, but would only restrain them from publishing the fact. And why should they be prevented from making the public aware of it, thus producing a false impression that the applicant is on the register when in truth he is not?

Injunction dissolved.—*The Times*.

## Medical News.

**UNIVERSITY OF GLASGOW.**—The following candidates have passed the Fourth (Final) Professional Examination for the degrees of M.B. and C.M. :—

*Candidates who took Pathology in Fourth Professional Examination.*—

Harry Gleghorn Anderson, Charles James Babes, Thos. Barrowman, Edward Beck, Robert Bishop, John James Boyd, William Limont Brown, Archibald Chalmers, M.A., James Easton Chalmers, David Charters, John Cochraue, William Craik, John David Davies, Richard Gregor Dick, Thomas Divine, Jas. Fisher, William Fulton, Henry Niven Gardiner, James Gillespie, Peter Napier Grant, Thos. Hamilton, David Harris, William Sandilands Harrison, William Moffat Holmes, Robert King Howat, John Johnson, Hugh Kerr, M.A., David Clark Laird, Robert Langmuir, M.A., John Lindsay, M.A., James Buchan Littlejohn, Edward James Morris, William M'Niven Muat, Percy Hope Murray, Alexander Christie M'Arthur, James M'Glashan, James Angus Macintosh, Jas. M'Kay, Alexander John M'Kechnie, George M'Lauchlan, Peter Carmichael M'Robert, Charles O'Neill, William Adam Paterson, Robert Ramsey, William Robertson, Leonard Alfred Rowden, Thomas Leadbetter Shields, William Northcote Sime, Alexander Robb Smith, Charles Stewart, David Robert Thomson Strong, David Wallace, Andrew Watson, John Watt, John Whitehouse, Charles Frederick Wylie, Alfred Alex. Young, M.A., John Cameron Young.

*Candidates who passed Pathology in Third Professional Examination.*

William Henry Mason Alexander, James Ebenezer Bow, William Brodie Brodie, Wm. Mackenzie Brown, Archd. Prentice Campbell, David Birrell Campbell, James Carslaw, M.A., Andrew Cluckie, James Cochrane, Robert Cook, Alexander Baillie Craig, James Ritchie Dalrymple, John Stanley Davies, M.A., John Don, M.A., William Walton Don, Neil Downie, Alexander Robert Ferguson, Andrew Findlay, Alfred Forrest, M.A., Jas. Fisher Frew, Andrew Graham, Robert Guy, James Blair Hartley, Aeneas Henderson, Ernst Denny Scott Heyliger, Henry Edward Jones, Neil Keith, Thomas Kirkwood, M.A., Thomas Donald Laird, Hugh Lawrie, Hamilton Clelland Marr, Robert M'Farlane Marshall, Jas. Donald Rae Monro, M.A., John Morton, William Cochrane Murray, John Hardie MacArthur, William M'Call, Alex. Hutchison M'Cracken, John M'Donald, M.A., Alex. Stewart M'Pherson, Wm. M'Walter, George Nicoll, John Paterson, M.A., Wm. Findlay Paton, M.A., William John Richard, M.A., James Jenkins Robb, James Andrew Robertson, Maurice Tancred Stack, William Steel, Wm. Caldwell Steele, John Barr Stevens, Robert Taylor, James Thomson, John M'Donald Vallance, Andrew Wauchope, Charles Wilson, William Semple Young.

The undermentioned gentleman has passed the Final Examination for the degree of M.D. (old regulations):—

Robert Cook, L.R.C.S.E.

**SOCIETY OF APOTHECARIES OF LONDON.**—The following candidates have passed in the respective subjects:—

*Surgery.*—E. C. Adams, St. Barthol.; W. Ashby, Guy's; R. S. Berry, St. George's; F. Clarke, St. Barthol.; W. B. Clarke, Belfast; G. Cross, St. Thomas's; C. G. L. Dähne, St. Barthol.; C. P. T. Edwards, University Coll.; C. G. Hoysted, Charing-cross; E. A. Humphreys, Owens Coll.; G. C. Jeaffreson, University Coll.; F. Melandri, Bologna; H. W. Oborn, St. Thomas's; R. N. U. Pickering, St. Barthol.; H. Richardson, Owens Coll.; A. B. Rogers, Owens Coll.; R. L. Romer, St. George's; G. Schilling, St. Thomas's; T. A. B. Soden, Charing-cross; S. J. Stuck, Middlesex; A. J. Temperley, London Hosp.; L. P. Tomlinson, St. George's; W. E. Toyne, Edinburgh; C. Webb, St. George's; W. R. Willey, St. Mary's.

*Medicine, Forensic Medicine, and Midwifery.*—H. S. Elliott, St. George's; W. H. F. Noble, University Coll. and London Hosp.; E. Le F. Payne, St. Mary's; H. R. Phillips, Cambridge and Manchester; H. E. B. Porter, London Hosp.; J. H. F. Way, St. Thomas's; S. Wilkinson, Liverpool.

*Medicine and Forensic Medicine.*—F. Melandri, Bologna; A. L. Roper, Cambridge and Guy's Hosp.

*Medicine and Midwifery.*—F. A. Arnold, London Hosp.; W. R. Clarke, Belfast; G. Cross, St. Thomas's; W. D. Johns, Durham; G. W. Lilley, Yorks Coll., Leeds; J. N. Martin, St. Barthol.; G. A. Peake, Bristol.

*Medicine.*—H. J. van Leent, Guy's.

*Forensic Medicine and Midwifery.*—S. P. Hopewell, London Hosp.; J. A. Procter, King's Coll.; F. Spurr, Middlesex; A. J. Temperley, London Hosp.; J. B. Tindall, King's Coll.

*Forensic Medicine.*—H. F. Ransome, Owens Coll.; S. A. L. Sodipe, University Coll.; C. Webb, St. George's.

*Midwifery.*—W. D. Akers and F. N. Roth, St. Mary's.

To Messrs. Ashby, Hoysted, Humphreys, Phillips, Pickering, Porter, Ransome, Rogers, Romer, Sodipe, Spurr, Toyne, Way and Webb was granted the diploma of the Society entitling them to practise Medicine, Surgery and Midwifery.

**MEDICO-PSYCHOLOGICAL ASSOCIATION.**—The following gentlemen have passed the examination of the Medico-Psychological Association of Great Britain and Ireland, entitling them to the certificate in Psychological Medicine:—At Aberdeen, on July 16th: Messrs. F. S. Ainley, G. Cruikshank, A. B. Dalgetty, A. Davidson, R. Ferguson, W. Hector, F. Kelly, T. B. Law, G. B. D. Macdonald, W. C. Pieris, W. H. de Silva and R. S. Trotter.—At Edinburgh, on July 18th: Messrs. S. C. Brush, C. R. Nair, D. A. Welsh and J. B. Yeoman.

**MEDICAL MAGISTRATE, AUSTRALIA.**—Dr. Victor Black, of Southern Cross, Yilgarw, West Australia, has been appointed a Justice of the Peace.

**THE General Practitioners' Alliance** have passed a resolution expressing the opinion that charities which bestow indiscriminate medical relief and levy fees upon the sick and needy should not be allowed to participate in the Hospital Sunday and Saturday Funds.

**COTTAGE HOSPITAL FOR NUNEATON.**—A cottage hospital is to be erected for this town and district on a site given by Messrs. J. Tomkinson and R. Stanley, situated near the Midland Railway Station. The estimated cost of the building is £2000. The subscriptions amount to £2388 18s.

**BRISTOL MEDICAL MISSION.**—The ceremony of opening the new premises in connexion with this mission in Redcross-street took place on the 19th inst. This much-needed enlargement will greatly add to and extend the sphere of the mission's usefulness.

**PRESENTATIONS.**—The members of the Aberdeen, Banff and Kincardine branch of the British Medical Association waited on Dr. Mackenzie Booth at his house on the 21st inst. and presented him with a pair of silver candelabra on the occasion of his approaching marriage.—Mr. T. M. Butler, M.R.C.S., of Guildford, has been presented by the members of the Loyal St. Mary's Lodge of Oddfellows, on his retiring from the position of the Lodge Surgeon, after upwards of thirty years' service, with a handsome silver salver.

**TRAINED MALE NURSES.**—The annual meeting of the Hamilton Association for providing Trained Male Nurses was held last week. The seventh annual report stated that the number of male nurses on the roll at the end of June was thirty-one. Of these, twenty-two were employed, three were off duty by their own request and six were available for duty. There had been an increase in the number of men employed in hospital work during the year. Both financially and in other respects the position of the Association was satisfactorily improved.

**ROYAL SEA-BATHING INFIRMARY, MARGATE.**—On Saturday the annual meeting was held in connexion with this infirmary. It was stated that of 220 beds in the institution 140 had been closed for want of funds. To this cause the present financial condition was chiefly attributed. The late Sir Erasmus Wilson made a gift to the infirmary of a new wing which he intended to endow, but died before completing the bequest, thus entailing upon the committee an outlay of £10,000 to finish the work and to purchase a new recreation ground in place of that built upon. The invested capital had in consequence been largely utilised, and it is estimated that by closing 120 beds £2000 a year will be saved and the income then will be about adequate to discharge the necessary expenditure.

**COLLEGE OF STATE MEDICINE.**—The annual meeting of the Fellows of the College of State Medicine was held on the 22nd inst., Sir Thomas Crawford, K.C.B., in the chair. The report for 1891 was read and adopted. The work of the college had been very successful during the year and the college had been self-supporting. Further efforts will be made to extend its usefulness as a teaching institution in connexion with public health. Sir Joseph Fayrer gave confident expression to his belief in an extended sphere of usefulness for the college. Established on sound principles, and supported and conducted by men with no motives of self-aggrandisement, it was certain of ultimate success. In this vast metropolis, crowded with institutions and societies of all kinds, it sometimes happened that the useful and deserving were temporarily overshadowed. But, whenever the basis was a sound one and the work done was honest and thorough, a full measure of success was only a question of time. Dr. Fleming suggested that greater efforts should be made to give publicity to the scope and work of the college. Although the numbers who took advantage of the teaching of the college were large and steadily increasing, he felt certain that if its educational advantages were better known the increase would be much more rapid. Professor J. Lane Natter brought before the notice of the meeting the large numbers who present themselves for examination in Hygiene under the scheme of the South Kensington Science and Art Department, and suggested that the teaching, which is at present confined to medical men, should in some way and in different classes be made available to teachers and others.

**HOSPITAL SATURDAY FUND.**—The total amount at present received on behalf of this fund has reached nearly £11,000.

**SCARLET FEVER AT SHIPLEY.**—In consequence of the prevalence of scarlet fever in Shipley district it has been decided to close all Sunday schools until the end of August.

**THE ISLE OF MAN HOSPITAL, DOUGLAS.**—The annual report for the past year shows that excellent work was done during the year and that there had been an increase in the subscriptions and donations.

**THE Princess of Wales** has forwarded to the British Home for Incurables a cheque for £150, being the second instalment on account of the sale of Canon Fleming's sermon, "Recognition in Eternity."

**THE GREAT NORTHERN CENTRAL HOSPITAL.**—At the opening ceremony of the bazaar recently held at Hampstead in aid of the building fund of the Great Northern Central Hospital it was announced that a gentleman, who at his own request remains for the present anonymous, had offered to subscribe £500 to the hospital if nine others would follow his example. The committee have since received two similar promises.

**EARLSWOOD IDIOTS' ASYLUM, REDHILL, SURREY.**—The forty-fifth annual report shows that steady progress had been made during the past year in all the departments. Cases from all classes in society are pressing for admission and from all parts of the kingdom applications are received seeking advice and direction. The largest number of inmates in residence in any year was attained in 1891. Scientific modes of training have been tried, both physical and mental, with marked success. Finance causes anxiety; the expenditure last year exceeded the income and left a liability of £500 to the bankers.

**SANITARY INSPECTORS' ASSOCIATION.**—Dr. B. W. Richardson presided at a general meeting of this Association held at the Carpenters' Livery Hall, London Wall, on Saturday. The report presented recommended, upon the question of examination for sanitary inspectors, that the Council should be empowered to confer with the Court of the Carpenters' Company with the view to arrange for lectures and examinations. A report was also submitted upon the Association's recent visit to Paris, which deals with the chief features and incidents of the journey. The chairman, in supporting a motion for the adoption of the respective reports (which was agreed to), stated that the Association had learned many important lessons on sanitation by their visit to Paris.

**LEAD IN TARTARIC ACID.**—At Woolwich Police-court, before Mr. Kennedy, Mr. George Mence Smith, oil and colourman, who owns a great number of retail shops, was summoned by the Local Board of Health for selling tartaric acid containing 0.0026 per cent. of lead, equivalent to 0.18 grain of lead per pound; and citric acid containing 0.037 per cent. of lead, equivalent to 2.59 grains of lead per pound. Mr. E. Hughes, M.P., supported the complaint, and Mr. Blanchard Wontner appeared for the defence. It was agreed to take the case of the tartaric acid first. Professor W. R. Smith, public analyst and medical officer of health for Woolwich, said he had analysed a sample of tartaric acid purchased from one of the defendant's shops, and certified that it was adulterated as alleged in the summons. Lead was an accumulative poison, and one twenty-fourth of a grain in a gallon of water would be injurious. Lead got into tartaric acid probably in the course of manufacture, either by the use of sulphuric acid or by the preparation of the article in leaden vessels. Care in manufacture would avoid it. For the defence Dr. John Muter was called. He agreed with Dr. Smith's analysis, but totally disagreed with his conclusions. An ordinary bottle of lemonade would contain eight grains of tartaric acid, and a man would have to take about 220 bottles per day, according to this analysis, before he consumed one-twentieth of a grain of lead. Mr. Connor, of Wandsworth, said he had large experience in whitelead colic, and considered that the quantity of lead in this tartaric acid was too small to affect health. Mr. Kennedy dismissed the summons, and the matter of the citric acid, together with several other cases of a similar character, was adjourned.

**BIRMINGHAM AND MIDLAND EYE HOSPITAL.**—The work accomplished by the institution during the past year is very satisfactory. The limit formerly placed on the number of beds occupied—namely, thirty-five—is now removed. This and the previous year's accounts showed a substantial balance of income over expenditure, and the conditions accompanying Miss Rylands' generous gift having been complied with, the committee were enabled to increase the work of the hospital by the treatment of an additional number of in-patients, for which the institution was adapted. The total number of patients treated was 22,478, an increase on last year of 1049.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

- DONAGAN, A. E., L.D.S. R.C.S. Edin.**, has been appointed Dental Surgeon to the Royal Institution for Deaf and Dumb Children, Birmingham.
- DRUMMOND, J. H. G., L.R.C.P., L.R.C.S. Edin.**, has been appointed a Public Vaccinator in South Australia.
- EKINS, A. E.**, has been appointed Public Analyst for the County of Hertfordshire.
- FARR, E. A., L.R.C.P. Lond., M.R.C.S.**, has been appointed Medical Officer to the Post-office, Andover.
- FENWICK, W. SOLTAU, M.D. Lond., M.R.C.P.**, has been appointed Medical Tutor to the London Hospital.
- HARKIN, C. F., M.B., B.Ch. Dub.**, has been appointed a Public Vaccinator for Wodonga, Victoria, Australia.
- HAYWARD, ARTHUR E., M.R.C.S., L.S.A.**, has been appointed Public Vaccinator for the Brixham and Churston Districts of the Totnes Union, vice Green, deceased.
- HILL, A. B., M.D. Glessen, L.R.C.P., L.R.C.S., D.P.H. Camb.**, has been appointed Public Analyst for the county of Warwickshire.
- HUXTABLE, L. R., M.B., C.M. Edin.**, has been appointed an Official Visitor to the Hospital for the Insane at Parramatta, New South Wales.
- KAUFFMANN, O. J., M.D. Lond., M.R.C.P., M.R.C.S.**, has been appointed Physician for Out-patients and Pathologist to the Queen's Hospital, Birmingham, vice Crooke, resigned.
- KEBHELL, C., L.R.C.P. Lond., M.R.C.S.**, has been appointed Honorary Visiting Physician to the Brisbane Hospital, Queensland.
- KERR, J. A., M.B., C.M. Glasg.**, has been appointed Health Officer for the District of Ellistoun, South Australia.
- LAKE, RICHARD, F.R.C.S.**, has been appointed Registrar and Pathologist to the Hospital for Diseases of the Throat, Golden-square, W.
- MARIS, C. F., M.D. Irel., M.R.C.S.**, has been appointed Honorary Visiting Surgeon to the Brisbane Hospital, Queensland.
- MCKINNON, A. A., M.R.C.S., L.R.C.P. Lond.**, has been appointed Assistant House Surgeon to the Royal Albert Hospital, Devonport, vice Dr. J. George, resigned.
- MORSHEAD, E. G. A., M.D. Brussels, L.R.C.P. Lond., M.R.C.S.**, has been appointed Surgeon to the Loyal St. Mary's Lodge of Odd-fellows, vice Butler, resigned.
- ROBERTSON, GEO., M.B., C.M. Aber.**, has been appointed Medical Officer to the Glenfoundland Lodge of Oddfellowes, Insch, Aberdeenshire, vice Dr. G. B. Currie, resigned.
- SCANLAN, C. E., M.B., C.M. Glasg.**, has been appointed Government Medical Officer and Vaccinator for the District of Port Macquarie, New South Wales.
- SPEECHLY, HARRY MARTINDALE, M.R.C.S., L.R.C.P. Lond.**, has been appointed House Surgeon to the London Hospital.
- STEELE, JONATHAN, I.R.C.P. & S. Edin., L.F.P.S. Glasg.**, has been appointed Medical Officer of Health to the Kingsgrove Local Board, Stoke-on-Trent, vice A. B. Great Rox, M.D., resigned.
- STURGE, W. HOWARD, M.R. Lond.**, has been appointed House Physician to the London Hospital.
- SYMONDS, HORATIO, F.R.C.S. Edin.**, has been appointed Consulting Surgeon to the Faringdon Cottage Hospital.
- TAYLOR, W. F., M.D. Canada, M.R.C.S., D.P.H. Lond.**, has been appointed Honorary Ophthalmic Surgeon to the Brisbane Hospital, Queensland.
- TEICHELHANN, E., I.R.C.P. Irel., F.R.C.S. Eng.**, has been appointed Surgeon-Lieutenant in the Medical Department, South Australian Military Forces, and also appointed a Public Vaccinator in South Australia.
- THOMSON, J., M.B., C.M. Edin.**, has been appointed Honorary Visiting Surgeon to the Brisbane Hospital, Queensland.
- TILSTON, E., L.R.C.P. Edin., M.R.C.S.**, has been appointed Honorary Visiting Surgeon to the Brisbane Hospital, Queensland.
- TURNER, N. H., L.R.C.P. Lond., M.R.C.S.**, has been appointed Surgeon to the Royal Institution for Deaf and Dumb Children, Birmingham.
- WARDEN, CHAS., M.D. Aberd., F.R.C.S. Edin., M.R.C.S.**, has been appointed Honorary Consulting Surgeon to the Royal Institution for Deaf and Dumb Children, Birmingham.
- WILSON, T. S., M.B. Edin., M.R.C.P. Lond., M.R.C.S.**, has been appointed Honorary Consulting Physician to the Royal Institution for Deaf and Dumb Children, Birmingham.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

- COUNTY ASYLUM, Shrewsbury.**—Junior Assistant Medical Officer. Salary £100 per annum and £8 in lieu of beer, with board, lodging and washing.
- DOCTOR, 2, New-rents, Ashford, Kent.**—Junior Qualified Assistant for a Medical Association.
- GENERAL HOSPITAL, Birmingham.**—Two Assistant House Surgeons for six months. Residence, board, and washing provided.
- LEEDS PUBLIC DISPENSARY, New Briggate.**—Junior Resident Medical Officer. Salary £85 per annum.
- LONDON LOCK HOSPITAL AND ASYLUM, Harrow-road, W.**—House Surgeon. Salary £100 per annum, with board, lodging and washing.
- MANCHESTER ROYAL EYE HOSPITAL.**—House Surgeon. Salary £70 per annum, with residence, board and washing.
- ROYAL UNITED HOSPITAL, Bath.**—Honorary Physician.
- TOTTENHAM HOSPITAL.**—Resident House Surgeon for one year. Salary £90 per annum.
- WREXHAM INFIRMARY AND DISPENSARY.**—House Surgeon. Salary £80 per annum, with furnished room, board, gas, coal, and attendance.
- WORK RETREAT.**—Senior Assistant Medical Officer. Salary £150 per annum, with board and lodging.

## Births, Marriages, and Deaths.

### BIRTHS.

- BROWN.**—On July 23rd, at Bedford House, Chiswick, the wife of James Brown, M.B., Tring, of a daughter.
- CUTFIELD.**—On July 25th, at Merton House, Ross, Herefordshire, the wife of Arthur Cutfield, B.A., B.Sc., M.R.C.S., of a daughter.
- LINDSAY.**—On July 3rd, at Heber City, Utah Territory, U.S.A., the wife of D. M. Lindsay, L.R.C.P., L.R.C.S.I., of a son.
- PAYNE.**—On July 22nd, at Wimpole-street, the wife of Joseph Frank Payne, M.D., of a daughter.
- PHILLIPS.**—On July 16th, at Grosvenor-street, W., the wife of John Phillips, M.A., M.D. Cantab., F.R.C.P., of a son.
- SCOFIELD.**—On July 17th, at Netherfield, Notts, the wife of Harold Scofield, M.B., B.Sc., of a son.

### MARRIAGES.

- BEALE—ATTWELL.**—On July 25th, at St. Mary's, Barnes, by the Rev. Dr. Wace, Principal of King's College, London, assisted by the Rev. B. Meredith Kitson, M.A., Rector of the Parish, Peyton T. B. Beale, F.R.C.S., of 61, Grosvenor-street, London, only son of Professor Lionel Beale, M.B., F.R.S., also of 61, Grosvenor-street, to Gertrude Louisa, youngest daughter of Professor Attwell, K.O.C., of Fern Lodge, Barnes.
- BENNETTS—KNOTT.**—On July 23rd, at St. George's Episcopal Church, Edinburgh, John James Bennetts, M.B., C.M., of Brompton, Chatham, to Gertrude Elizabeth, daughter of Tavernor Knott, Artist, Edinburgh.
- BENSON—COOPER.**—On July 26th, at St. Peter's, Eaton-square, Alfred Hugh Benson, M.R.C.S., L.R.C.P., of Wrington, Somerset, to Marie, second daughter of the late Richard Cooper, of Higham Court, Sittingbourne.
- BOSTOCK—PERRY.**—On July 21st, at St. Peter's, Eaton-square, Surgeon Robert Ashton Bostock, Scots Guards, son of Deputy-Surgeon-General John Ashton Bostock, C.B., Hon. Surgeon to the Queen, to Mary Catherine, eldest daughter of Brigade-Surgeon George Perry, of St. George's-square, S.W.
- HUTCHINSON—HUTCHINSON.**—On July 13th, at the Westminster Meeting-house, St. Martin's-lane, Procter Selby Hutchinson, M.R.C.S., second son of Jonathan Hutchinson, F.R.S., of Cavendish-square, to Alice Mary, eldest daughter of the late Edward Hutchinson, of Haslemere, Surrey.
- OWEN—DAVIES.**—On July 20th, at Llanymynech Parish Church, by the Rev. I. L. Wynne-Jones, Rector of the Parish, assisted by the Rev. W. Thomas, Vicar of Bwlch-y-Cibau, Owen Trafford Owen, M.B., C.M., of St. Albans-place, Blackburn, to Marian Elizabeth, eldest daughter of J. W. Davies, of Yrnyrn Bank, Llanymynech.
- PARSONS—PARKINSON.**—On July 21st, at Holy Trinity Church, Tunbridge Wells, Frederick George Parsons, M.R.C.S., to Maria, widow of the late John Lechmere M. Parkinson, of Ludford Park, Ludlow.
- WATERHOUSE—HARKER.**—On July 27th, at the Church of St. Lawrence, Middleton St. George, co. Durham, by the Rev. John Groves, Vicar of Redcar, assisted by the Rev. C. Jackson, M.A., Rector of the Parish, Herbert Furnival Waterhouse, M.D., C.M. Edin., F.R.C.S. Eng., of 81, Wimpole-street, Cavendish-square, W., eldest son of the late Rev. Charles J. Waterhouse, M.A. Cantab., to Edith Florence, only daughter of John G. Harker, Esq., Middleton St. George.

### DEATHS.

- HEIM.**—On July 17th, at 4, St. Ann's Villas, Royal-crescent, Notting-hill, Charles Mungo Heim, M.R.C.S. Eng.
- LOWER.**—On July 21st, at Olveston, Gloucestershire, Nynlan Holman Lower, M.R.C.S., L.S.A., eldest son of the late Mark Antony Lower, of Lewes, Sussex, aged 52.

*N.B.*—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."

We cannot undertake to return MSS. not used.

### CERVICAL RIBS.

*Editor.*—Our correspondent will find the literature on this subject in the various papers and works to which the following references apply, but may, we think, obtain most information from papers by Dr. Struthers. One of these is published in the *Monthly Journal of Medical Science* for 1858 ("On Rudimentary Ribs and their Relation to the Vertebrae"); another in the *Journal of Anatomy and Physiology* for 1874-5 ("Variations of the Ribs and Vertebrae in Man"—see Cervical Ribs, p. 32). There are papers also by Sir W. Turner in the *Journal of Anatomy and Physiology* for 1869-70 and 1882-83; Mr. W. Lane, *Guy's Hospital Reports*, 1833-34, p. 100; Professor R. W. Reid, *Proceedings of the Anatomical Society*, 1889-90; Dr. Dymock, *Edinburgh Medical and Surgical Journal*, 1883, p. 304; Dr. Willshire (case), *THE LANCET*, vol. ii, 1860, p. 633; Dr. Beavor (case), *Trans. Med. Soc. Lond.*, 1890, p. 505; Dr. Clarke, *Glasgow Medical Journal*, 1874; Mr. Cones, *Science*, Cambridge, 1884, vol. iii. ("On Free Cervical Ribs in the Human Subject"); Dr. Jewett, *Am. Anat. and Surg. Soc.*, Brooklyn, vol. i., 1878-80; Dr. Shepherd, *American Journal Med. Soc.*, Philadelphia, 1883. He might also consult Meckel's *Manual of Anatomy*; Gillette, *Bul. Soc. An. de Paris*, 1869, p. 72; Lebacqz, *Pascal, Romiti, &c.*

### AN APPEAL.

To the Editors of THE LANCET.

Sirs,—You were good enough in May, 1890, to insert an appeal from us on behalf of Mr. Thomas Comfield. He is a physician who has by advancing paralysis been wholly incapacitated for many years and confined entirely to his bed for more than six. The response to our letter placed at our disposal a total of £132 10s., which we have sent to him in sums of £5 per month. This fund is now exhausted, and as Mr. Comfield's circumstances remain as before we are obliged to make another appeal. He is almost unable to move, and needs the constant attendance of a skilled nurse. His relatives are not able to afford him anything beyond very trifling pecuniary help, and his case is one worthy of the active sympathy of those of our profession who can afford to render him assistance. We shall either of us be glad to take charge of donations for him.

We are, Sirs, yours faithfully,

J. HUGHLINGS JACKSON, 4, Manchester-square, W.  
July 16th, 1892. JONATHAN HUTCHINSON, 15, Cavendish-square, W.

The following subscriptions towards a second fund have been received:—

Sir Andrew Clark ..	£10 10 0	Messrs. Wakley, Editors	
Dr. Hughlings Jackson..	10 10 0	of THE LANCET ..	£10 10 0
Mr. Hutchinson ..	10 10 0		

### HOW TO OBTAIN DIABETIC FOODS ABROAD.

To the Editors of THE LANCET.

Sirs,—A diabetic patient wishes to visit Paris, Rheims and Bourges. Can you give me the addresses of any confectioners in those towns who sell gluten and almond breads?—I am, Sirs, yours faithfully,  
Melkham, Wilts, July 20th, 1892. S. GROSE.

\*\* Cormier, 18, Rue des Grands-Augustins, is the most reliable and best maker of gluten and other diabetic foods in Paris. We do not think it likely that there is any actual maker in Rheims or Bourges, but in those places it could be procured by parcel post from Paris and even without difficulty from London. If not obtained direct in this way, a pharmacist, and not a confectioner, would be the proper person to apply to for it.—ED. L.

L.S.A. Lond., if under the new examinations, is not likely to be molested if he calls himself "surgeon apothecary." The other title mentioned is due only to graduates of universities.

## INTERVIEWING MEDICAL MEN.

*Interviewer.*—For a medical man to suffer himself to be interviewed on medical questions would be contrary to the spirit and traditions of the profession. He would not only lay himself open to a charge of indirectly advertising himself and his opinions, but of setting a bad example in a profession which above all others is a quiet profession, and one dealing with delicate subjects that cannot be blatantly and dogmatically discussed to suit the newspaper style. Every medical man who sets his face against such practices deserves the thanks of his profession.

## "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS.—Your correspondent, Mr. J. B. Pike, does not seem to have grasped the situation. There is nothing to be gained by saying "the fact of the matter is this," and then putting forward one's own views, but I think we all agree that the fact that qualified men are found glad to accept the small salaries offered by medical aid associations is due to the still more extreme smallness of the salaries offered by medical men to their assistants, and to the want of capital which renders the latter unable to buy or found practices. The man who graduated at the very bottom of his class buys a practice soon afterwards, and pays his old classmate, the first man of his year perhaps, £125 a year to do work for which the patients pay £1000 a year. For £2000 suppose he buys £1500 a year net, puts two-thirds of the work and all the drudgery on his assistant, knowing that the work will be better done than if done by himself, and thus, besides the opportunity of earning £500 a year by his own work, gets 60 per cent. on his capital. The assistant feels that he is badly treated and yet cannot resist, but the patients, learning that they pay £1000 for what can be had for £125, form a medical aid association, give the former assistant a salary of, say, £250, and thus, though obtaining exactly the same services, save £300 or £700 a year. The late principal is of course vexed at losing a large part of his income and calls his rival hard names, a "degrader of the profession," a "public sinner" and so on; and forgetting that he himself had been a party to a contract in which a qualified man undertook certain work for £125 a year, denounces as "low" one by which twice that sum is earned for the same work. He has, however, only himself to blame, for had he been content with 20 or 25 per cent. interest on his capital his assistant would have had such a salary as would make him refuse the association's offer. It is hardly necessary to say that I am not referring to any particular case, but illustrating by an example the method of dealing with assistants which is, I believe, largely responsible for the formation of the societies mentioned. As to Mr. Pike's plan of forming a "strong trade union" among medical men, by which the action of "the House of Commons might be treated with contempt," I may say that popular feeling would be opposed to such a union among men who have comfortable incomes, that it would be called by the odious name of a "ring" and if it gave any trouble would be declared illegal. Finally, as to the "impression upon the mind of the public," I may point out that the public know the value of medical services from the salaries offered to qualified men by advertisements in the press. When they see that one medical man values another at £50 a year and food &c. their opinion cannot be lowered by seeing a third take a much larger salary from a lay association.—I remain, Sirs, yours sincerely,  
July, 1892. VERAX.

## THE CARPENTER AND DUKES FUND.

To the Editors of THE LANCET.

SIRS.—Dr. Arthur Carpenter, son of my lamented friend the late Dr. Carpenter, and myself beg to return sincere thanks for your kindness in so generously responding to the appeal made on our behalf to defray the heavy expenses of the action brought against us (for £2000 damages), which costs the judge ordered to be paid by the plaintiff. We also beg to thank our friends, Dr. Coles, the treasurer and Mr. Richardson, the secretary, of our Croydon Medical Society, for their kind assistance and generous support, the South-Eastern Branch of the British Medical Association, the Council of the British Medical Association, and all other medical brethren who have kindly contributed towards the fund.

We trust that the Parliamentary Bills Committee will succeed in their efforts to frame a Bill for altering the defects in the protective clauses of the Lunacy Act, so that in future medical men shall not be subjected to an action at law unless a guarantee be given that the costs shall be paid by the party to whom the verdict shall be decided against by the jury. I may add that Dr. Carpenter earnestly hoped that the publication of our case might be the means of the lunacy laws being altered. We hope that his wish may come to pass very soon.

I am, Sirs, yours faithfully,

Wellesley-road, Croydon, July, 1892. M. C. DUKES, M.D.

## A COASTING TRIP.

To the Editors of THE LANCET.

SIRS.—In answer to your correspondent "A. E." I may state that I have at different times travelled by several of the steamers which ply around our coasts. Last year I made the trip to which he refers. The boat was a good one of its class. The accommodation for ladies was at best only moderately good, but it strikes me that what a lady would feel chiefly in a society which is usually masculine is the want of congenial companionship. I should, at all events, strongly advise "A. E." to make his first coasting tour alone. Going by himself he should be very comfortable.

I am, Sirs, yours truly,

M.

## KILLED BY LEECHES.

A HORRIBLE story comes to us from Vallombrosa, "Milton's Paradise," as it has been called; a favourite summer resort in the Apennines for the residents in Florence. Among the inmates of the *Hôtel de la Savoie* there was the Commendatore Giordani, Director-General of Mines in the Ministry of Agriculture and Commerce. On the evening of the 14th he went out for a walk and, being known to suffer from impaired health, his friends were very anxious when, after the lapse of some hours, he did not return. A prolonged search was made by a number of domestics provided with lanterns, and they were about to abandon it as fruitless when one of them heard a feeble moan coming from a pit at the foot of a steep incline. A descent was made to the spot, and there the unfortunate gentleman was found, still alive, with no injury to bone or limb, but "literally beset by a myriad of leeches" ("letteralmente assalito da una miriade di sanguisughe"). He was at once removed to the hotel and attended by Dr. Cesare Paggi, afterwards assisted by Professor Del Greco. But the loss of blood inflicted on an enfeebled constitution proved fatal, and, in spite of assiduous care and skill, the Commendatore died within three days of his rolling down into the pit.

F. E. N.—We do not believe it was ever intended by the Act that a fee should be charged under the circumstances mentioned. Such a charge is a distinct hardship and ought to be resisted. Attention should be called to the case.

Mr. C. Gregory, Salford.—Any application of this sort should reach us through a medical man.

P. R.—It should be treated like the midwifery fees—divided.

Mr. L. Kidd.—Messrs. Leggett and Co., Bradford.

## THE LEGALITY OF MEDICAL STUDENTS ACTING AS ASSISTANTS.

To the Editors of THE LANCET.

SIRS.—Would you kindly inform me whether there is any law to prevent a medical student (unqualified) acting as an assistant to a duly qualified practitioner by visiting, dispensing and attending midwifery? Is an unqualified assistant (a student) liable to an action under the Apothecaries Act (1815) for visiting and prescribing?—Yours truly,

J. TAYLOR HANCOCK,

Amble, July 23rd, 1892.

Registered Medical Student.

\*\* To the first question we would say that, provided the medical student acts under the close supervision of the principal and resides under the same roof, neither he nor his principal is likely to be molested by the rules laid down by the Medical Council for the guidance of practitioners. We would refer our correspondent for these rules to THE LANCET of June 4th, 1892, p. 1209. To the second question we have to reply that we are not aware of any such action against an unqualified assistant, and that it is not likely to be commenced.—ED. L.

## "DURHAM CITY."

To the Editors of THE LANCET.

SIRS.—On page 232 of last Saturday's issue of THE LANCET I notice a paragraph headed "Durham City," in which your correspondent refers to the remarks made by the judge at the assizes recently held here with regard to some foul smell which existed in the court. I forward you a cutting from the *Durham County Advertiser*, of the 22nd inst., bearing on the point. I have made inquiries and am assured on the best authority that the explanation given in the paper is a perfectly correct one. Perhaps you will therefore be so good as to give publicity to the enclosed paragraph.—Yours obediently,

A. M. VANN,

Durham, July 26th, 1892.

Medical Officer of Health.

\*\* We append the paragraph enclosed by our correspondent.—ED. L.

"THE 'NUISANCE' AT THE ASSIZE COURTS.—In the remarks passed at the Assize Courts last week his lordship was considerably wide of the mark in his opinion as to the smell of which complaint was made. As a matter of fact there was not the slightest defect in the sanitary condition of the Assize Courts, and the unpleasant smell was created by the presence of a person who suffered from a peculiar disease. He was seated in front of Mr. Walton, Q.C., the complainant, and therefore the smell was likely to be more offensive to that gentleman than to anyone else. The true state of things was discovered shortly afterwards by the police and the man was asked to retire. He did so, and the nuisance no longer existed in court. His lordship's severe observations were therefore unmerited."

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. James Armstrong, Liverpool; Mr. W. Armstrong, Pontesbury; Messrs. Ash and Sons; Dr. Althaus; Mr. W. Anderson; Mr. Airey; Dr. Abram, Exeter; Mr. Brown, Douglas; Mr. Banerji, Calcutta; Messrs. Bishop and Sons; Mr. A. E. Broster, Wirksworth; Messrs. Bates, Henty and Co.; Dr. F. Beach, Darent; Mr. R. W. Barker; Messrs. Broome and Co., Oldham; Mr. Browning, Manchester; Messrs. Barker and Sons; Mr. Birchall, Liverpool; Mr. Burgess, Manchester; Mr. Byrne, North Devon; Dr. E. K. Campbell; Dr. G. Medical Diary for the ensuing Week.

Monday, August 1.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30 P.M.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

Tuesday, August 2.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.

Wednesday, August 3.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, August 4.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, August 5.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, August 6.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 16 3

TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES

ABROAD ..... One Year 1 14 8

\* In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 6d., instead of £1 16s. 10d. as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET Office, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

## Address in Bacteriology,

Delivered at the Meeting of the British Medical Association at Nottingham,

By G. SIMS WOODHEAD, M.D. ED., F.R.C.P. ED.,  
DIRECTOR OF THE LABORATORIES OF THE ROYAL COLLEGES OF  
PHYSICIANS (LONDON) AND SURGEONS (ENGLAND).

MR. PRESIDENT AND GENTLEMEN,—Had it been announced twenty years ago that one of the annual addresses delivered before this Association would be devoted entirely to a review of the subject, or part of the subject, of bacteriology, such announcement would have been received as coming under the category of prophecies not likely to be fulfilled; and without claiming any very large share of modesty or self-depreciation, I cannot but feel that it is to the unexpected fulfilment of this imaginary prophecy that I owe my present position—a position that would be only too eagerly sought after from the honour that its occupation confers on the holder, were it not that the responsibilities placed on his shoulders must necessarily weigh heavily enough to interfere most seriously with the full enjoyment of the honour. Bacteriology, though a comparatively new science, has already made so deep an imprint on the science and practice of medicine that the enumeration in catalogue form of the various facts upon which, according to our present knowledge, the solution of important medical and surgical questions depends would occupy a much longer time than we have at present at our disposal; it will be my aim, therefore, to indicate very briefly the extension and limitation of bacteriology in its relation to medicine. It may be stated at the outset that in this matter extremists have little claim to be considered, and that, although most thoughtful men maintain that bacteria play a most important rôle in the production of disease, it is equally certain that no claim for anything beyond such important share can be claimed for the most virulent of pathogenic microbes. Outside the question of the relation of micro-organisms to the special forms of surgical fevers, a knowledge of the life history of bacteria and the relation of these organisms to specific infective disease is essential to every scientific student of medicine; so definitely, indeed, has this come to be acknowledged that in all our Public Health examinations a knowledge of bacteriology is insisted upon, whilst in many of our civil and military appointments both at home and abroad a fairly intimate knowledge of the theories as to the relations of bacteria to disease is looked upon as constituting a most important qualification in the case of candidates presenting themselves for examination. If, then, the public services are taking up this position, how much more necessary is it that an important Association such as that which I have now the honour to address should wish to encourage its study by such means as they have in their power. As you are aware, some of the earliest and best work on bacteriology has been done by your research scholars, and many of those who have begun this work under the auspices of our Association have made it part of their life work. To mention one example only out of many, Watson Cheyne's accurate work on the life history of the bacillus tuberculosis and on the special relation of this bacillus to tubercle of bones and joints forms a most valuable contribution to bacteriology and surgery.

It has been too much the fashion to look upon bacteriology as an art rather than a science. It was supposed that if we were able to obtain evidence that a definite micro-organism was associated with a specific disease, and that if we could find a means of destroying this organism, or of preventing its access to the tissues the limits of bacteriological teaching would be reached. Thanks, however, to the genius of such men as Pasteur, Koch and Lister, bacteriology is now looked upon as a branch of science the study of which may afford us help in the solution of even fundamental problems in biology; it has assumed such importance that into its service have been pressed the general biologist, the botanist and the pure physiologist; whilst all who practise medicine and surgery feel that they must, at least, be conversant with the principles that underlie its study. I know there are some who will not agree with this, and who will tell us that we are bacteria mad; and whilst acknowledging that in taking up this comparatively new subject we may have been led to attach undue importance to it, it must be conceded that,

studied in its broader aspects, bacteriology has enabled us to grapple with some of the most difficult questions in medicine. Can an astronomer be accused of narrowness of vision because sometimes he may be found looking through the telescope which covers a limited field and is studying with especial care a small area of the heavens? Which of us can tell of the boundless space and the countless worlds that are opened up by these seemingly narrow studies? The observer collects his data, applies the laws of physical science as at present set forth, formulates and proves new laws, and opens up and argues on a world so utterly beyond us that his facts to those uninitiated read like the wildest fiction, and his descriptions like poetry and romance.

It would be a waste of your time were I to attempt to trace the history of fermentation, of putrefaction, of septic conditions and of the relation of bacteria to certain diseases, but it may perhaps be of advantage to insist that there has been a continuous evolution and extension of our theories in regard to the nature of the action and interaction of bacteria on the tissues and organs of the human body. First, there was the mechanical theory, in which it was maintained that death of the host was due to the impaction of groups of micro-organisms in the capillary vessels; then came the theory that these organisms used up the oxygen so rapidly that the tissues received an imperfect supply and somatic death ensued. Both of these may be partial explanations, but we have now presented to us quite different explanations. The administration of phosphorus is followed by grave changes in the tissues, and fatty degeneration occurs—how this is brought about it is difficult to say; similar degenerations are found in certain diseases set up by micro-organisms. Do such organisms, then, when introduced into the body, act directly by taking up and using for their own purposes the oxygen which would otherwise be applied to the nutrition of the tissues? This appears to be very unlikely. Do they attack the tissues directly, making their way into the substance, and so devitalising them that they are unable to perform their proper functions? Do the products formed by these organisms act directly on the cells, and interfere with their functional activity, causing direct devitalisation and degeneration of the protoplasm? Do the cells, when called upon to perform extra work in getting rid of these organisms or of their products—both of which must be looked upon as foreign bodies—undergo such excessive stimulation that the supply of oxygen is not equal to the demand, and the functional activity of the cells being in excess of their facilities for nutrition, their protoplasm then undergoing changes described as cloudy swelling, which in turn are followed by fatty degeneration just as in phosphorus poisoning? At one time it would have been deemed impossible to answer these questions; but as the study of the chemistry of bacteria has been utilised, our information on these points has become more and more definite, and as this definite information has been obtained, it has become possible to indicate some at least of the processes that are going on in certain of the specific infective diseases, and to draw inferences, some of which, however, have still to be put to the proof, as to the methods to be adopted in waging war against bacteria. One of the most important outcomes of the study of the relations of bacteria to disease is that we have now a pathological chemistry which, though still in its infancy, has a great future. Hitherto physiological chemistry has merely been elaborated and extended in order that it might be applied to the examination of certain products and excretions met with as the result of diseased conditions of various organs; but beyond enabling us to make search for slightly modified physiological products, this physiological chemistry has helped us but little.

The influence that bacteriology has had on medicine and surgery is best appreciated when some special process or condition is followed in its etiology, progress and determination; for example, the study of bacteriology has revolutionised our conception of the whole subject of inflammation, and has enabled us to bring into harmony theories and interpretations of facts which hitherto have appeared to be diametrically opposed to one another. Virchow's observations on the changes in the fixed and parenchymatous cells were supposed to clash with those processes of emigration of leucocytes and changes in the walls of the vessels set forth by Wharton Jones, Waller, and Cohnheim and their disciples. A battle royal waged between those who held that there could be no inflammation without vascular phenomena and those who maintained that these vascular phenomena were merely secondary events. In connexion with this subject Metchnikoff has pointed out that

in the human subject and the higher animals, on which experiments were at first exclusively made, it is impossible to set up any definite irritative changes without calling to our aid traumatism or some form of chemical irritation; and also that in such experimental subjects even the tissues which in a normal condition are extra-vascular have, under the slightest irritation, a tendency to return to their embryonic vascularised condition. It was then found that certain bacteria when introduced into the tissues had the power of setting up rapid but easily followed inflammatory changes; and, lastly, the pathologist and the zoologist have combined to ascertain whether changes comparable to those set up in inflammation could be set up either by bacteria or through their irritant products, when brought in contact with lower unicellular organisms or with simple organisms in which no bloodvessels are ever developed, and another advance was made. Roser (quoted by Metchnikoff) maintains that inflammation is a disease due to infection by microbes and that the phenomena observed in repair are really the result of inflammation, or rather that they constitute those processes that end in resolution or the cure of inflammation itself. At one time such a theory would have been received with ridicule, and even now it is impossible to prove that inflammation is in all cases due to the presence of micro-organisms or their products.

It is only by a careful study of the processes described as occurring in lower organisms that we can gain any accurate conception of the differences in the processes set up by mechanical injury and those induced by the presence of micro-organisms. But we have now undoubtedly come to look upon inflammation as only one of a series of changes, all of which work towards a definite end: first, the getting rid of foreign bodies, whether organic or inorganic, whose presence might exert a deleterious influence on the tissues in which they are lodged; and, second, the repair of the breach that has been left at the point at which these foreign bodies have entered or been extruded.

The soluble products derived from pure cultures of micro-organisms are now known to be composed of a large number of different substances, to isolate which various attempts—many of them unsuccessful—have from time to time been made. None have been more successful than those carried on in this country by Burdon Sanderson, Sidney Martin, Halliburton, Brunton and MacFadyean, R. W. Philip, Hankin, Ruffer, Crookshank and Herroun, William Hunter, Cartwright Wood and others whose work, though not so frequently referred to, is still of great value. To no one was this fact more evident than to one whose loss to pathology we have now cause to deplore. I refer to Sir William Aitken, whose death deprives the profession of one whose greatest concern it was to advance and encourage the study of pathological chemistry—especially in the sense in which we are now using the term—amongst his followers. His address delivered before the Pathological Section of the Association at the meeting held in Glasgow was full of suggestion and of the results of research. He had grasped the true value of the subject, and although in recent years, owing to failing health, he had been unable to carry on original research himself, he was still able to leave the imprint of his mind on a subject the welfare of which he had so near at heart by the encouragement that he gave to younger men, both by his advice and by the enthusiasm which he still retained with his ripening experience. Another who had already done work at this subject, but who gave promise of much greater things, Dr. H. J. Tylden, whom many of us delighted to have as a friend and collaborator, has been cut off when his work still appeared to have been but begun. Dr. Tylden has gone, but the remembrance of his energy, cheerfulness and determination will remain as a help and stimulus to all who knew him and appreciated these features in his character. In order that we may focus more accurately the nature of the work which has been done in connexion with bacteriology let us confine our attention to a single disease—diphtheria—in which, as the result of the use of bacteriological and chemical methods in its study, we can now recognise with a moderate degree of certainty, not only that we have to do with a specific organism, but also how this organism acts. Loeffler, who first made pure cultures of the diphtheria bacillus, originally described by Klebs, found that, after removing the microbe from the liquid nutrient culture medium, by passing it through a cylindrical porcelain filter and injecting the filtrate into a guinea-pig he was able to determine not only the same kind of local reaction that was obtained when the organism itself was introduced into

the subcutaneous tissue, but also those paralytic symptoms so characteristic of the later stages of diphtheria. Then by extracting with a watery solution of glycerine, filtering, and dropping the filtrate into absolute alcohol he obtained a flocculent precipitate, which could be washed and re-washed with alcohol without passing into solution. This substance, readily soluble in water, still retained its power of setting up distinct local reaction after being washed, dissolved, re-precipitated, and again dissolved. Roux and Yersin, accepting Loeffler's statement that the poisonous material appeared to be a ferment-like body, repeated and extended his experiments. They made observations on the nature of the swelling set up at the point of inoculation by the organisms or by the poisons; they noted that, although there might be congestion and effusion into the serous cavities, evidences of fatty degeneration of the liver and kidney, and characteristic diphtheritic paralysis, no organisms could be found beyond the seat of inoculation. From this they argued that the poison formed at the seat of inoculation must be diffused by the lymphatics and bloodvessels into every part of the body; that it might attack the nervous and muscular tissues, especially apparently the peripheral nerves, so giving rise to degenerative changes in them and in those tissues which appear to be involved in the process of conversion, secretion, and excretion of the poisonous substances. These observations were entirely in accord with clinical experience. The degenerations that are met with in the kidney and in the liver in cases of diphtheritic animals are essentially similar to those found in children who have succumbed to diphtheria, whilst the symptoms of peripheral paralysis and the changes in the nerves appear in the two cases to correspond in the most minute features. These observers were convinced that it was some special part of the products of the diphtheria bacillus that gave rise to these symptoms, and they, after various experiments, came to the conclusion that the active substance was not actually precipitated by the alcohol, but that it was entangled and carried down by the alcoholic precipitate.

Sidney Martin, going a step further, succeeded in separating certain substances, each of which, appeared to exert a definite effect on certain tissues and functions, and to give rise to special symptoms and distinct pathological changes. He compared their physiological actions with those of similar or allied substances obtained from anthrax patients and cultures or from cases of ulcerative endocarditis and tetanus, and found that the albumoses—intermediate products between non-dialysable albumens and dialysable peptones, substances, comparable as regards their structure and chemical reactions to those formed during the process of peptic digestion, could be separated not only from the membrane of diphtheritic patients, but also from the spleen and blood of the same patients, and from pure artificial cultures, of the Klebs-Loeffler organism as cultivated by Klein and himself, and that they produced very definite local effects when injected subcutaneously—a condition that was usually accompanied by marked rise of temperature, paralysis, fatty degeneration of certain of the peripheral nerves—both motor and sensory—of the heart muscle and in a minor degree of certain other organs. These features were observable even when a single dose only was given, but were much more marked when small but oft-repeated doses were exhibited. The marked wasting and degeneration, which, in many cases appears to have been progressive and continuous, indicates that we have here to do with a direct poisonous action of the albumoses on the protoplasm of the tissues that they specially affect. Martin, who had previously described a powerful alkaloid or organic base in the products of the bacillus anthracis and in the blood and organs of anthrax patients, was naturally led to look for a similar substance in the diphtheria products; but here, as if to accentuate the difference that may exist between the poisonous substances produced by two different organisms, he found not an organic base, but a substance which he speaks of as an organic acid, as, although it was separable by the same processes as those used to isolate the base or alkaloid, it was found to have the characters of an acid. This organic acid had, however, the same—but markedly feeble—physiological action as the albumose, also giving rise to nerve degeneration.

In the diphtheritic membrane where—as in ulcerative endocarditis—the organism is growing on coagulated fibrin, a substance which is readily digested by and prepared for the nutrition of the organisms found in these diseases, albumoses are always found accompanied by an extremely

virulent substance entangled in the proteid of the membrane, and precipitated by alcohol. This substance is similar in all respects to the ferment-like body described by Roux and Yersin. It is attenuated by heat, destroyed by boiling, and is characterised by the same (but more intense) physiological actions as the albumose and the organic acid, extremely minute doses producing very grave symptoms. Diphtheria, then, is entirely dependent for its specific symptoms on the diphtheria bacillus, experiment corroborating clinical observation in a most remarkable manner. This bacillus does not readily attack healthy individuals, but where there is slight ulceration of the throat or slight fibrinous exudation on the surface of the tonsils or the posterior surface of the velum palati, diphtheria often makes its appearance. Sometimes the exudation appears to be associated with the local action of the diphtheria bacillus itself, but usually the diphtheritic process appears to be grafted on small patches of ulceration and exudations. Experiment offers the explanation of this fact. The diphtheria bacillus does not appear to have a very marked power of attacking healthy mucous membrane; but when it finds a nidus in devitalised cells and coagulated fibrin, it is able to produce its special secretion or "enzyme," part of which acting on the fibrin, just as the enzyme met with in the stomach acts on food, rapidly transforms the insoluble and undialysable fibrin into soluble albumoses, some of which in turn are utilised for the nutrition of the micro-organism, whilst the remainder of the enzyme and the products of its action on the fibrin, absorbed by the lymphatics and blood-vessels, are carried into the system, where they act on the tissues and organs already mentioned, and, after being broken down into lower molecular combinations, are excreted. Before, however, we can accept this ferment-like body as an enzyme, the power of conversion of a large quantity of proteid must be more definitely proved. It is to the presence of these three sets of products that the symptoms of diphtheria and the changes met with in the tissues are due, and, as Martin points out, all three sets of poisonous substances may be obtained from pure cultures of the specific diphtheritic organism. In diphtheria, then, the bacillus is the primary infective agent. It, as a result of its vital activity, produces a powerful enzyme—Martin's secondary infective agent. Part of this enzyme, acting locally on the coagulated fibrin on which the organism is subsisting, converts it into various soluble products known as albumoses; some of the enzyme, being absorbed, continues the process of conversion in those tissues and organs in which it is allowed to remain long enough in contact with the proteids contained in the fluids of the body. This conversion, as Martin indicates, is especially well marked in the spleen, through the spaces of which the blood passes extremely slowly, so that it is allowed to remain in contact with the enzyme for some time, during which the albumoses are broken down into much less complex chemical substances, the most important of these in diphtheria being the organic acid, whilst in anthrax it is an alkaloid or organic base, the less complex organic acid being less virulent than the albumose, whilst those bodies of still less complex molecular constitution appear to be little more noxious than ordinary effete products.

The semi-final product of the bacillus of anthrax is, however, the most active cause of death, the alkaloid exerting a far more powerful physiological action than the intermediate albumoses which in diphtheria act so much more energetically. It is interesting to note how the definite changes set up by these poisons correspond to those set up by inorganic poisons, such as phosphorus, antimony and by some of the organic compounds which induce fatty degeneration through a direct action on the protoplasm, which—unable to obtain extra-cellular material to carry on its functions under increased stimulation—has to fall back, as it were, on its own protoplasm, which is rapidly converted from proteid into fatty matter. Here, then, with the protoplasm overstimulated and wasted, and with the products of the micro-organism still present in the blood, the process of wasting becomes progressive; owing to the previous wasting normal stimulation is now excessive; the degeneration may go on even after the poison has been removed, and ultimately the patient may die of failure of certain organs when all danger from the direct action of the poison appears to have passed by. We now know that in the case of the microbes of suppurative, hog cholera, tetanus, tubercle and some other diseases the poison is actually combined with the protoplasm of the micro-organism, and it is quite possible that in these cases of "marasmus," or progressive wasting, the toxine may

be given up for long after the organisms themselves are dead, and thus may keep up well-marked irritation and stimulation of the protoplasm; the condition of "marasmus" continuing after the microbes are dead, and therefore—as was at one time supposed—innocuous. Bacteriological chemistry thus supplies another diagnostic factor in the detection of specific infective disorders. Martin points out that to Koch's four cardinal rules a fifth may be added—that is, that the secondary infective agent, the chemical poison separable from the tissues in the natural disease, should exert a definite physiological action, and that this poison should be similar, both chemically and physiologically, to the products obtained from a pure artificial culture of the primary infective agent—the micro-organism. Specific chemical differences may not always be present, but by combining what we know of the chemistry of these products with their physiological or pathological action we may still be able to determine how far a disease is specific, and how far, therefore, it is due to the presence of a primary infective agent. By the assistance of the above factor it may be possible to unravel the etiology of certain disorders which up to the present have defied the most pertinacious efforts of the pathologist and bacteriologist. It is not within the reach of everyone engaged in general practice to make chemical examinations; though, from the lucid way in which some of our recent workers have set forth their methods, it is a comparatively easy matter to carry on the first stages of the processes from which point the expert may continue the research. It is possible, however, as Roux and Yersin have pointed out, for everyone engaged in the attendance on patients in whom the presence of diphtheria is suspected to settle the question for themselves, and to gain information, not only for their own guidance in the treatment of the case, but also for the use of the medical officer of health, whose duty is often rendered both difficult and unpleasant, where any doubt as to diagnosis in such cases exists. Roux and Yersin find that if they remove part of the diphtheritic false membrane by means of a platinum needle flattened at the end, to form a kind of spatula, pass the same needle without recharging over the surface of a series of layers of specially prepared blood serum, and incubate at from 33° to 35° C., the diphtheria bacillus is the only one of the commoner micro-organisms that makes its appearance within twenty hours. Colonies visible to the naked eye as small rounded greyish-white points (the centre of which, owing to the somewhat greater thickness, is more opaque than the periphery) are then seen. So rapid is the further growth of these colonies that they are large, well-developed discs before any other organisms form colonies at all visible to the naked eye; from these pure cultures may be readily obtained, and may be examined at once or sent to some expert bacteriologist. The appearance and rapidity of the growth alone are quite sufficient to justify the medical attendant of the case in deciding that he is dealing with diphtheria, information which cannot be obtained by ordinary methods of diagnosis, especially in those very doubtful cases where the patches are comparatively small and ill-defined. Quite recently Shukaroff has utilised the boiled white of egg as a culture medium for this diagnostic purpose. He takes a boiled egg, carefully removes half the shell, and with a knife that has previously been heated cuts from the surface small strips just large enough to go into a test tube, which has first been sterilised by heat in the following manner. Put two-thirds of an inch of water into a test tube, plug the opening with cotton wool, and allow to boil briskly over a spirit lamp or Bunsen flame. As soon as a little more than half of the water has boiled away, put aside to cool; the egg is then placed in the tube. Cultures are made as on the serum, and incubated at from 35° to 38° C., and at the end of twenty-four hours small greyish growths, from which cultures or cover-glass preparations may be made, appear on the glistening surface of the coagulated albumen. This process may not be quite so accurate as the serum method, but it is so easy to carry out that it should prove invaluable as a diagnostic aid in doubtful cases of diphtheria.

I should here like to suggest that the Association for the Advancement of Medical Research, which has already done such valuable work, not only in encouraging but also in controlling research might undertake to assist in this matter. If properly supported by the profession it might supply media of various kinds to those who wish to engage in this kind of work, for, although it is entirely a matter of money at present, it cannot but be felt that a small subscription (if a large number of members of the profession would take this in hand) would be ample to enable such

a scheme to be carried out; and, moreover, although I do not see how the Conjoint Colleges could be expected to do more than they have done in facilitating research in this country, I am convinced (though I have not broached the subject) that if any well-matured plan, backed by sufficient funds to pay for a couple of young men who with slight training in experimental work would be able to prepare and do the rough examination of material, were put before them, they would not be unwilling to place some accommodation at the disposal of the Society in order that the scheme might have a fair chance of proving a success. A retaining fee might be paid to certain experts, whose duty it should be to give reports on specially interesting cases. At present there is no organisation or centralisation; specimens, badly preserved, are sent up in a haphazard way, accompanied or followed by a note to the effect that it is hoped that the person to whom they are sent will examine and send a report. If the expert happens to be interested in the special subject he will make a very thorough examination and will forward a report sooner or later; if he is not, the chances are ten to one that the specimen will be left until he has sufficient leisure after he has done his own proper work, and as young men of our profession are as a rule not endowed with too much of the good things of this world, they are usually so occupied with their own investigations and with trying to make both ends meet, that the examination is put off to the Greek kalends. If, however, men were specially retained and were paid a moderate fee for each investigation, they would be eager to do the work and would feel that they were not neglecting their own interest or the interests of those dependent upon them, whilst those for whom the examinations are made would have far less reluctance in sending specimens for examination were they but assured that they were taking up no one's time without making some adequate return. Not only so, but an investigation for which a fee is charged is always of more value both to practitioner and patient than an examination—done in the leisure moments of a friend or acquaintance—for which no charge is made. I should not have mentioned this matter did I not believe that pathology suffers very greatly from the want of some such organised plan of work; it is not a matter which any private individual can take up, but it is one that if taken up by the Association mentioned—especially if backed up by a grant from this Association—might prove of enormous value to the profession at large. It would, of course, be necessary to make a fixed charge for each examination, the charge varying with the nature of the work; but it might be that every subscriber of a guinea and upwards per annum should have the privilege of having his specimens examined for half the tariff price.

I had intended to deal to-day with the subject of anti-toxines—that is, substances which are said to be formed when bacteria or their poisonous products are injected into the fluids or tissues of an animal, and which are supposed to be the important factors, not in the production of immunity, but in the actual cure of specific infective diseases. I find, however, that Sternberg, in a recent address on the practical results of bacteriological researches,<sup>1</sup> goes into this matter very thoroughly, and gives a short summary of the results obtained in numerous experiments with anthrax, rabies, diphtheria, tetanus, croupous pneumonia, swine erysipelas, and also with ricin (the active poisonous principle in the castor-oil bean), and abrin (the similar product of the jequirity bean), all of which are brought forward to support the theory that wherever a poison is developed in the body an anti-toxine—a substance which is supposed to neutralise the effect of a poison—is rapidly developed, with the result that neither specific organisms nor their poisons can continue to have any effect on the animal host. Many of the experiments made by different observers who have laid claim to the presence of these anti-toxines have failed to give results in the hands of other workers. It cannot, merely on this ground, be assumed that the first results are inaccurate, for all who have experimented with bacteria know only too well that the results they have been able to obtain have differed so greatly when the conditions of the experiment have been only slightly modified, that the personal element of the equation in these problems, in which we are to a certain extent groping in the dark, must necessarily be a most important factor. On the other hand, it should be distinctly understood that until the crucial experiments have been repeated time after time, in different schools, and under known conditions by all who

are determined to obtain reliable data, we are not justified in accepting them as proved.

Allowing that many of the experiments are perfectly trustworthy the results obtained by various workers at different diseases have been so contradictory that it may well be asked what is the explanation of such divergences. In the first place there is not a sufficiently marked line of demarcation drawn between the curative action of the anti-toxines and the production of immunity; the two are perfectly distinct, though they are too frequently inextricably confounded in respect to the interpretation of experiments. For example, it is quite possible that an anti-toxine when introduced either into a pure culture of a specific organism or in the body of an animal in which this organism is growing may prevent or neutralise the action of the toxine formed by this same organism, whilst it may not exert the slightest influence in inducing an increased insusceptibility to the attack of the same organism; on the other hand, it is found, as Metchnikoff has recently demonstrated for hog cholera, that the serum from an animal vaccinated against this disease (which is then supposed to contain the anti-toxine), just as in the case of serum from an unvaccinated animal, allows of a most luxuriant growth of the hog cholera organism, and that it certainly exerts no anti-toxic action when injected into an animal suffering from the disease. But when the serum from a vaccinated animal is injected from time to time into the circulation of a non-vaccinated animal, it is found to confer, just as Martin found on injecting anthrax blood similarly treated, a very marked insusceptibility to the specific disease, whilst the serum of animals not previously rendered immune when injected into non-vaccinated animals exerts no protective influence, the disease being developed just as in animals previously unexperimented upon.

If now we consider that this serum from vaccinated animals serves as an excellent cultivating medium for the growth of the micro-organism of hog cholera, as, too, we find that when sterilised products of a culture of hog cholera bacillus or the blood taken from an immune animal do not interfere with the action of the special poison when introduced simultaneously into the circulation, it must be concluded that such sterile product does not act directly either on the bacillus or on the poison produced by the bacillus; on the other hand, as this same substance introduced into the circulation of the animal undoubtedly exerts a certain protective influence we are compelled to the conclusion that this serum—or rather some body present in it—must act directly on the protoplasm of the cells of the body. Metschnikoff argues that it must act as a stimulant, for it is generally accepted that there is a definite protection for most specific diseases. It is of course not necessary to assume that only the migratory leucocytes are so modified, for although the leucocytes, on account of their motility and powers of migration and emigration, are first called upon to resist the attacks of invading organisms and their products, all the cells—especially those in contact with the circulating fluids—must be modified as they come in contact with the poisons carried in these fluids, and thus be gradually inured to carry on their work, even under extremely disadvantageous conditions; for there can be little doubt that these other cells have frequently to help, under special stimulation, to join issue with the micro-organisms and their products that have passed beyond the sphere of operation of the leucocytes at the point where the primary invasion occurs. It is to this ultimate modification of the protoplasm of the cells of the body under the influence of organic or inorganic therapeutic agents that we must look for our future triumphs in the treatment of specific disease where vaccination has not been resorted to, or has failed. Of such direct action on protoplasm there are only two or three examples, but there can be little doubt that quinine and arsenic in malaria, and mercury and perhaps iodide of potassium in syphilis, act somewhat in this manner. Should it be definitely proved that anti-toxines are formed as the result of the action of certain bacteria on the tissues and fluids of the body, an anti-toxic method of treatment—as at present within our reach—could prove of little practical value, for in the cases where any definite results have been obtained very large quantities of the blood or serum from immunised animals have been used in order to obtain the results described, and it is difficult to imagine how it would be possible to obtain for our purpose sufficient of the specific anti-toxines from living animals, however vaccinated, whilst the risks to patients would be so great that such treatment would be unjustifiable. We may, however, still hope for something better, especially when in the British Institute

<sup>1</sup> International Journal of the Medical Sciences, July, 1892.

of Preventive Medicine men can devote their whole time and energy to the study and preparation of vaccines and anti-toxines, their nature, actions and doses. Such work is too difficult, and the results at stake are too important, to be left to share with other duties the attention of any man or body of men.

There is one point of view from which we must look at these chemical products quite apart from the organisms that produce them. One of the theories as to the effect of such chemical poisons in protecting an animal against the attacks of any but the most virulent organisms or against enormous doses of less virulent organisms must, so far as our knowledge goes, be based on what may be called the acclimatisation theory, according to which various cells and tissues of the body become so accustomed to the presence of certain poisons when administered in small but gradually increasing quantities, at definite intervals, that when large doses are actually formed within the body the tissue cells are still able to react, to carry on their phagocytic functions, and thus to treat pathogenic organisms as mere saprophytes. Such a consideration as this would at present lead us to classify the methods of inoculation into at least two groups: those where the tissues have to become accustomed to the presence of a poison only, as in diphtheria and endocarditis, in both of which the poison can be developed only at the surface of the body, where fibrin or some similar substance is present but is so far removed from the action of the cells that the organism is able to grow and produce its special poison, the local tissues being directly attacked by both bacilli and poison, but the general tissues having the poison only carried to them. Tetanus might also be included in this group, though the conditions are somewhat different. Here it may be possible to acclimatise the tissues (as also in the case of hydrophobia) that the poison which, under ordinary accidental conditions, finds its way into a wound would have practically no effect, in which case the organisms introduced at the same time would also be dealt with by the tissues. In the case of diphtheria and infective endocarditis, where an enormous quantity of poison may be formed, and where, as we know, products administered experimentally have devitalised the tissues instead of increasing their resistance, the hope of inoculation proving useful does not seem to be very bright, though it may be that the introduction of exceedingly minute doses at certain definite intervals may confer a certain degree of protection. Where, however, pathogenic organisms are able to make their way into the lymphatics and bloodvessels, the prospects of obtaining good results from inoculation are much more favourable, as, if once an animal can become accustomed to the presence of the poison, the microbe itself can have little chance with the leucocytes and the tissues.

The two processes—the anti-toxic and immunisation by specific acclimatisation—are perfectly distinct from those on which Koch's treatment of tuberculosis is said to depend for its success. If a certain quantity of a sufficiently dilute escharotic be injected under the skin slight inflammation accompanied by exudation of leucocytes, proliferation of the connective tissue cells and localised formation of new connective tissue, is set up. If, however, a first dose be followed by a second, a second by a third larger and more concentrated dose, the tissues may undergo necrotic changes, a slough is formed, and what is called reaction takes place; and the slough gradually separates from the reacting tissues in which connective tissue is formed. This is exactly what takes place when tuberculin is administered; the tuberculin alone is not sufficient to cause any serious damage to the tissues, but along with the poison that is formed by the tubercle bacilli in the areas affected, it intensifies the necrotic action associated with tubercle, especially in the immediate neighbourhood of the bacilli, and in this way the partially devitalised or dead tissues may be got rid of more rapidly by sloughing than in cases in which no treatment is attempted. Sad experience, however, has taught us that the increased dose of the poison so acts on the tissue in the zone some distance from the area of actual sloughing that in certain cases, at any rate, it becomes much more susceptible to the attacks of the tubercle bacilli, and thus the disease seems to spread more rapidly after the administration of tuberculin; and although it is possible, though certainly not yet proved or even probable, that very minute doses of tuberculin may have a salutary and perhaps a protective influence as regards the tissues, the clinical results up to the present have not been sufficiently satisfactory to encourage the hope that we have in tuberculin a substance that will exert any permanent favourable influence on the course of an attack of tuberculosis.

It is fitting that at a meeting of medical men whose aim is the advancement of science some slight attempt should be made to show that one of the greatest advances in the history of bacteriology has been initiated by members of this Association. It is only recently that in again going over the literature of anthrax I have come to a knowledge of certain facts, and although I was constantly associated for eight years with my friend and master Professor Greenfield, he never once mentioned a claim to what I now look upon as justly his due in connexion with the preventive inoculation of anthrax.

Duguid, as reported by Burdon Sanderson in 1880, had observed, in 1878, that when splenic fever or anthrax is transmitted by inoculation from cattle to small rodents, such as young guinea-pigs, and then back again to cattle, the character of the disease so transmitted is much milder than that of the original disease acquired in the ordinary way; the rodents die but the bovine animals inoculated with their blood or with the pulp of their diseased spleens recover. There seemed to be little doubt at the time these experiments were made that the question as to the attenuating effect of passing the bacillus anthracis from a cow to a guinea-pig had been settled, though from the fact that cattle appear to be much less susceptible to direct inoculation than they are to the bacillus when introduced by the alimentary tract, doubts have been expressed as to the real value of these experiments, as although the same anthrax when passed through a series of guinea-pigs appeared to have its virulence diminished, there was not sufficient proof given that the attenuating influence which appeared to exist extended to those cases where feeding experiments were conducted. These doubts, however, cannot detract from the value of the observations made, as they were, at so early a period. In view of Pasteur's success in the production of an attenuation of the microbe of fowl cholera this appeared to give promise of successful results in the production of immunity against the attacks of anthrax. In May, 1880, Greenfield, who at the Brown Institution had made careful cultivation and inoculation experiments on the anthrax bacillus, announced in "An Inquiry into the Nature, Cause and Prevention of Splenic Fever, Quarter Evil and other Diseases,"<sup>2</sup> that he had been able by artificial means to prepare a protective anthrax virus. After referring to Duguid's experiments and the results obtained by the direct method of inoculation, Greenfield says: "Seeing that the object of my experiments was to inoculate bovine animals with a virus modified by its transmission through the guinea-pig, it may appear that it would be desirable in order to have the full effect of such modification either to inoculate directly from the guinea-pig or from a cultivation not far removed from it. But there would be many practical advantages if it were found that having once transmitted the virus through one guinea-pig or a series of them, its modified property was subsequently maintained in the artificial cultivation. I have therefore kept this in view, and have tested the effect of successive generations of the artificially prepared poison." He further says: "It would have been a great advantage if I had been able to test side by side with these cultivations derived from the guinea-pig other cultivations derived direct from a bovine animal. But in every case cultivations from the latter have failed owing to the commencement of decomposition in the material sent to us."

Using an infusion of the hay bacillus or aqueous humour of the sheep or ox—more especially the latter—Greenfield made his cultivations in closed glass tubes about a quarter of an inch in diameter, drawn out at both ends to a fine capillary tube and sealed. These tubes, about an inch in length and half filled with cultivating fluid, were carefully inoculated with a capillary tube containing a minute quantity of the blood, or only rubbed on the spleen of the animal which had died of anthrax, were sealed immediately after inoculation and kept at a temperature of about 35° C. After carefully describing five experiments made on cattle and sheep, in which the results were certainly most satisfactory, Greenfield says: "It must be evident to anyone who considers the matter that there are many points which must be determined by experiments of a much more extensive character than any I am able to carry out at the Brown Institution. If, as I hope, it should prove on further experiment that the earlier

<sup>2</sup> Vol. xvi. of the Journal of the Royal Society of England. (I mention this paper because it was published rather earlier than the note in the Proceedings of the Royal Society, and because the evidence there given as to the success of this method is far more complete and satisfactory than that contained in the latter paper.)

results are confirmed and that the inoculation of bovine animals with the bacillus anthracis, cultivated artificially after transmission through guinea-pigs or some other animal, serves to render bovine animals totally or partially insusceptible to the disease when transmitted by the usual channels, one great step will have been taken. But there will yet remain the questions: Is the mortality from inoculation by this method a high one, or do even a small percentage of animals die? What are the conditions under which inoculations may be best performed? Does age exercise an important influence in the fatality? Lastly, for how long a period is protection from attack conferred?" "To settle these points the inoculation of a large number of animals will be necessary, and their subsequent exposure to sources of contagion at favourable periods." These facts and statements, taken in conjunction with the observations published in the Proceedings of the Royal Society for June of the same year, make it evident that in his serial cultivation experiments, during which he obtained attenuation of the virus, Greenfield's object was to obtain a vaccine which, when inoculated, would induce a milder but protective attack of the disease with which he was dealing; and whatever fault may now be found with the methods used—and it must be remembered that at this period bacteriology was an almost new science, and the methods were only in process of development—he obtained the results at which he was aiming. It has been stated that his results could not be relied upon; but these statements are not based on his experiments, or on those carried on in the way that he described, but on various modified experiments. I have therefore thought it necessary to repeat a number of his experiments, following his directions as accurately as possible; and as a result, although they are not yet completed, I have found that although I may not be able to agree with all the interpretations put on the observations, the main facts themselves are unassailable, especially as regards the modification of the appearance of the organism under cultivation in the media mentioned—modifications that have been said not to exist. At the time that Greenfield was obtaining his results with cattle Toussaint was working away on young dogs and sheep, and in July, 1880, he described the results that he had obtained on these animals, and a little later he gave his method of preparing the attenuated virus with which he protected animals against the action of a virulent anthrax. In connexion with Toussaint's experiments Pasteur, than whom few men have been less rash in drawing conclusions, was satisfied that his method of preparing vaccine was valueless; but Roux, an exceedingly accurate and careful observer, and one of Pasteur's disciples, repeating the experiments, corroborated the results obtained by Toussaint; he found that his earlier experiments, published immediately after those of Greenfield, were to be relied upon, and that although the bacilli were destroyed at 55° C., the spores remained alive, and, what was more important, their virulence was attenuated.

Owing to the conditions under which scientific work must be carried on in this country, and to the comparatively slight interest that is taken in these matters by our wealthy classes generally, and owing to the restrictions that were placed upon the most necessary experiments, Greenfield was unable to test on a large scale the value of his observations, but he had laid the foundation of what was ultimately to become one of the greatest discoveries in modern medicine, and there can be little doubt that Wooldridge, in working out his admirable and epoch-making researches on protective inoculation, was following and extending these original researches carried on in the Brown Institution, where so much valuable work has from time to time been carried out. In stating this I am not detracting in the slightest degree from the brilliant work done by M. Pasteur, who, thanks to the wonderful results that he had previously obtained in other departments of research, was able to command the opportunities of carrying on his work on a most magnificent scale; and his results, published in May, 1881, may be said to be an edifice built on a triple foundation of his own work on fowl cholera, and that of Greenfield and Toussaint on anthrax; for although, as Pasteur pointed out, the earlier workers had not been able to eliminate many fallacies, theirs was the rough pioneer work which opened up a new country, cut rough and often circuitous roads, and made possible the advance of those who were to build up and elaborate the work that has since been and is still being done.

There is an old fable that when Truth was sent by the gods, owing to some mishap it fell from the clouds of Olympia to the hard, matter-of-fact world below, and was smashed into

a thousand atoms. Not only had Truth been beautiful in itself, but the shattered fragments still retained so much beauty of form, colour and material that each became the desire of those amongst whom it fell. In the general scrimmage that ensued many took part, and some were successful, each bearing away in triumph his small fragment, he and his friends fondly imagining that it represented the whole beautiful image. Gentlemen, the first step towards reconstructing this image is for each one to acknowledge that his fragment is but part of a great whole; when this is done let each bring his own fragment, be it large or small, and submit it for examination and measurement, and to be fitted by himself and by others. From time to time men of deeper and wider views than ourselves, capable of fitting together not only their own fragments, but those of others that have been prepared to their hands, come forward, and the original form is being daily further and further outlined. We are now but gathering and combining the smaller fragments into larger pieces, and it may be that in this finite existence of ours we shall see the limbs or joints merely, but through the association and working together of many, all animated by the same desire, these smaller fragments will be gradually fitted together, so that even we, in our time, may gain some conception, however crude and imperfect, of the wonderful form of Truth as it left the gods.

### A REPORT ON THIRTY-SEVEN CASES OF TUBERCULOUS DISEASE OF THE HIP-JOINT, FOR WHICH EXCISION OF THE JOINT WAS PERFORMED IN THIRTY-SIX CASES.

By BILTON POLLARD, M.D., B.S. LOND., F.R.C.S. ENG.,  
ASSISTANT SURGEON TO UNIVERSITY COLLEGE HOSPITAL AND SURGEON  
TO THE NORTH-EASTERN HOSPITAL FOR CHILDREN;

AND

C. F. MARSHALL, M.D., CH.B. VICT.,  
HOUSE PHYSICIAN TO THE METROPOLITAN HOSPITAL, KINGSLAND-ROAD  
N.E.; LATE SENIOR HOUSE SURGEON TO THE NORTH-  
EASTERN HOSPITAL FOR CHILDREN.

(Concluded from p. 256.)

#### STATISTICS OF THE COMPLETED CASES.

FOR convenience of reference we have given below the statistics of these cases in a tabular form. We shall here deal with the main points more in detail.

1. *Period of healing.*—Primary union (including cases in which the tube track healed by granulation shortly after primary union of the rest of the wound) occurred in 11 out of the 17 cases. Of these, 4 remained permanently healed and had no secondary operations, and 4 others remained healed for more than a year after excision before recurrence occurred. In addition to these we may add 2 cases (T. S— and J. A—) which also healed by primary union and remained healed for two years and one year and nine months respectively before recurrence, thus making a total of 10 cases which healed by primary union, and remained sound for a year or more. The date of first healing in the other cases was from three to fifteen months, as shown in the table. The period of final healing of course varies much according to the date of recurrence; this is given in each case in the table below.

2. *Recurrence of disease.*—In a total of 20 cases (including the 17 completed cases and 3 others which remained healed for more than a year after primary healing) recurrence of disease occurred in 16; in 9 of these further bone disease was found; in the others the bones were not further affected. In 5 cases there was only one secondary operation; in 5 cases there were two, in 3 cases three, in 2 cases four, and in 1 case five secondary operations. It will be seen by referring to the table that those cases which had most secondary operations performed were as a rule the cases in which further bone disease occurred.

3. *Real shortening.*—In the 17 complicated cases the actual shortening was between 1 and 2 in. in 9 cases, 2 in. in 5 cases, 2½ in. in 1 case, 3 in. in 1 case, and 3½ in. in 1 case.

The average shortening is 1.85 in. In the 2 cases which have 3 in. shortening part of the trochanter was removed.

4. *Apparent shortening.*—This, as seen in the table, was as a rule less than the actual shortening, the difference being due to slight abduction of the limb, or to some compensatory curve of the spine. The average apparent shortening is 1.3 in.

5. *Condition of joint.*—In 2 cases there was immobility of the joint, in 4 cases there was scarcely any mobility, in the remaining 11 cases there was more or less free mobility.

STATISTICS SHOWING THE EFFECTS OF FLUSHING AND DRAINAGE OF THE JOINT.

We shall here endeavour to show what bearing these points have on the time of primary and final healing. Cases admitted with sinuses are not included.

1. *Flushing.*—The treatment was adopted in twelve excisions, Mr. Barker's flushing curette being as a rule the apparatus used. In these, primary union occurred in 7 cases. One case died from shock after the operation. The remaining 4 cases were healed in three and a half, four and a half, twelve, and six and a half months respectively. Four of the flushed cases had no recurrence of disease up to the time when last seen; one of the 4 cases is that which died of diphtheria; 3 other cases remained sound for thirteen, fifteen, and twenty months respectively before recurrence; the remaining 4 cases are as yet too recent to consider in regard to final healing. The effect of flushing is therefore favourable as regards the primary healing of the wound, 7 cases out of 12 having healed by primary union, whereas only 11 out of 25 healed by first intention when flushing was not resorted to. Recurrence of disease appears to occur frequently whatever method of treatment be adopted.

2. *Drainage.*—In order to consider the effect of drainage

on the primary healing of the wound we may divide the cases into (a) those which were not drained, (b) those which were drained for from eighteen to forty-eight hours, (c) those which were drained for longer periods. As before, cases with sinuses are not included. Seven cases were not drained; of these, 5 healed by primary union. Eight cases were drained for from eighteen to forty-eight hours; of these, 6 healed by primary union. Thirteen cases were drained for periods varying from four days to several weeks; of these, 7 healed by primary union, with granulation of the tube track without suppuration. In short, healing by primary union occurred in 71.4 per cent. of cases not drained; in 75 per cent. of cases drained up to forty-eight hours; while 53 per cent. of cases drained for longer periods healed nearly by primary union. Cases therefore appear to heal almost equally well whether drained or not up to forty-eight hours, but there is a disadvantage in keeping up drainage for a longer period.

STATISTICS OF CASES WHICH HEALED BY PRIMARY UNION.

Of the 18 cases which healed by primary union, including those cases in which the tube track healed shortly afterwards by granulation without suppuration, in a clinical sense, 4 remained sound permanently and had no secondary operations; these cases were seen last two years and five months, two years, one year and eleven months, and twelve months respectively after excision. One other case remained sound up to the time it was last seen, but this was too early for the possibility of recurrence to be excluded. Six more cases remained sound for periods between one and two years. One case died early from an intercurrent affection. In the 12 cases in which recurrence took place there was further bone disease in only 5 cases. The table of these cases shows the date of recurrence after primary healing, the date of final healing, reckoned from the date of excision, and the number of secondary

† Recurrence in bone.

operations. The final results in those cases which are completed will be found by referring to the table of completed cases. The following conclusions may be drawn:—1. The primary healing must have been fairly complete and by no means limited to the superficial tissues in the majority of the cases, for the hips appeared to be quite sound and the scars continued healthy for many months even in the cases where disease subsequently recurred. 2. That it is desirable to secure primary union if possible, not only in order to prevent the risks of septic suppuration, but also with a view to the better subsequent progress of the case. Fifteen of the cases are sufficiently advanced to be considered in regard to recurrence of the disease; 5, or one-third of them, had further disease of bone. With these may be contrasted 14 cases which did not heal by first intention; 7, or half of them, had further disease of bone.

#### COMPARATIVE RESULTS OF EARLY AND LATE OPERATIONS.

In order to elucidate this point we have studied 20 cases which were operated on more than a year ago, more recent cases being excluded; cases which died and those admitted with sinuses are also excluded. The duration of the disease before operation is stated in each case in the two tables, the one of cases which healed by primary union, the other of completed cases. By referring to the former table it will be seen that the duration has little if any influence on the primary healing, as the list includes cases of various durations, from five months up to five years. Also, by referring to both tables, it is difficult to show that the duration of disease has much bearing on the final results. It should, however, be borne in mind that whether the case had progressed slowly or rapidly the same indications for operation were observed—viz., the presence of a superficial abscess and extensive disease of the joint.

We believe that the cases recorded and analysed above afford an average sample of the results which are obtainable by the mode of treatment which was employed. The immediate mortality, however, we believe to be higher than it ought to be, and higher too than it would be found to be if a larger number of cases were analysed. The results, if considered from all points of view, appear to us to be much less encouraging than the advocates of the methods followed were led to anticipate would be the case. But, whilst making this admission, we feel that no other plan of treatment can offer better results in similar cases—similar not only in regard to the stage to which the disease had progressed, but similar also in regard to the social position of the patients.

## THE ONTOGENY AND PHYLOGENY OF THE BREAST.

By W. ROGER WILLIAMS, F.R.C.S. ENG.,

LATE SURGEON TO THE WESTERN GENERAL DISPENSARY, AND SURGICAL REGISTRAR TO MIDDLESEX HOSPITAL.

### SECTION I.—INTRODUCTORY.

THE mammae are glandular organs destined to secrete milk for the nourishment of the young immediately after birth. Correlated with these important organs are other structural peculiarities, so that morphologists classify all animals having them in the same order under the name "mammalia." All such animals are viviparous; their young are brought forth naked, without any foetal envelopes or stored-up nourishment. Hence they usually depend for very existence upon the ability of the mother to nourish and protect them.

The origin<sup>1</sup> of the mammae is intimately connected with

<sup>1</sup> Mammalian animals are among the most highly organised and latest evolved. It was formerly thought that they came into existence at the commencement of the tertiary period; but it is now known that the leading types, as at present existing, were even then differentiated; and mammalian remains have since been found throughout almost the whole of the secondary or mesozoic rocks. As at present known mammals are completely isolated from all other groups of animals. Huxley believes we must go straight down to the amphibia for their nearest progenitors. According to Darwin (*Descent of Man*, 1879, p. 166) the descent of man from the lowest mammalia is through the ancient Monotremata to the ancient Marsupials, and from these to the early progenitors of the placental mammals. Thence to the Lemniridae and through these to the Simiidae. The latter then branched off into two great stems: from the catarrhine or old-world division, of which—after they had diverged from the new-world division—man, at a late period, proceeded. The time at which this took place is still a matter of controversy. It is, however, much more remote than historians and

this helpless condition of the young. Both sexes of human beings, like all other mammalian animals, possess mammae, but in males they are usually small and functionless. It is only in females that they develop into true milk-secreting organs. In this their perfect state, the mammae must therefore be regarded as appertaining essentially to the female organisation. It is, however, certain that it was not always so. We must remember that the earliest and most primitive sexual relation was hermaphroditism, and that the separation of the sexes as they at present exist was only secondarily effected, by division of labour, in the gradual progress of evolution. Hence in every male we still find rudiments of female reproductive structures, and *vice versa*. But it is chiefly in consequence of sexual selection that male animals differ so widely from their females, and that they tend to vary anatomically and pathologically in a different manner. Thus were developed the so-called "secondary sexual characters"; that is, those differences between individuals of opposite sexes which appear, not in the sexual organs themselves, but in other parts of the body, such as the beard of man and the breast of woman. It is certainly very remarkable that in every female all the secondary male characters, and in every male all the secondary female characters, exist in a latent state, ready to be evolved under certain conditions. Thus in men and male mammals the breasts occasionally attain a large size and secrete milk. To account for the existence of male mammae Darwin<sup>2</sup> suggests that long after the progenitors of the whole mammalian order had ceased to be androgynous, both sexes yielded milk, and that the males aided the females in suckling their offspring, but that afterwards, from some cause (as from the production of a smaller number of young), the males ceased to give this aid; disuse of the organs during maturity would lead to their being inactive, and this state would be transmitted to the males at the corresponding age. Curiously enough, the male mammae are much less completely aborted than are the other female reproductive-structures rudimentary in man. Having no use, the persistence of such structures is remarkable.

### SECTION II.—ONTOGENY OF THE GLAND.

The human breasts (mammae), like those of all other mammalia, are generally regarded as greatly enlarged and modified cutaneous sebaceous glands. The observations of Champneys<sup>3</sup> on the development of mammary functions by the axillary sebaceous glands of women during lactation, as well as those of Duval<sup>4</sup> on the nature of the secretion of the acinous glands of the areola under like conditions, show that the difference between sebum and milk is only one of degree. In all this it appears to me there is nothing to countenance the extraordinary view recently advanced, that in human beings highly specialised organs like mammae and teeth, which have taken immense ages to attain their present degrees of perfection, can be suddenly evolved as "sports" from ordinary sebaceous glands and cutaneous epithelial processes respectively. I must protest against this assumption, which is a contravention of the fundamental principle of heredity; and as I have elsewhere shown,<sup>5</sup> the evidence on which it is based is altogether delusive. The question has arisen whether the

chronologists have led us to believe. The oldest of such records prove that civilised communities and large states flourished in Egypt and some parts of Asia, prior to 4000 B.C. In these countries, therefore, man must have had far higher antiquity than this. In Europe his presence can be traced in this way only to about 2000 to 3000 B.C. Geologists have, however, proved his existence at much more remote periods. Geikie says (*Prehistoric Europe*, p. 2 et seq.): "We know now that many long centuries before the advent of the Romans our islands were occupied by a people whose knives and swords were fashioned of bronze; we know further that this people was preceded by a race or races ignorant of the use of metals, who lived during several considerable changes of climate and oscillations of the sea level; and we have also learned that at a still more remote period our country and the neighbouring parts of Europe were tenanted by tribes of yet ruder barbarians, during whose occupancy several extensive geological mutations occurred." Prestwichi's opinion on the subject is (*Antiquity of Man*, vol. II, 1888, p. 631) given thus: "If we can be allowed to form a rough approximate estimate—on data as yet very insufficient and subject to correction—we may give to Paleolithic man no greater antiquity than perhaps about 20,000 to 30,000 years; while should he be restricted to the so-called post-glacial period, this antiquity need not go further back than from 10,000 to 15,000 years before the time of neolithic man. The extreme antiquity of even 80,000 years (not to speak of 150,000 to 200,000 years)<sup>6</sup> assigned to man, seems to me based on very inappreciable evidence."

mamma is the homologue of a single sebaceous gland or of an aggregation of such glands. It appears to me that here we have but one reliable guide—viz., the ontogeny of the organ. Inasmuch as all observers are now agreed that the mamma is developed from but a single epithelial ingrowth, and that the form ultimately attained—in which the gland discharges by numerous ducts on the summit of the nipple—is due to secondary modification (kenogenesis), I am decidedly of the opinion that we must regard it as the homologue of but a single specialised sebaceous gland.

Like all other glands opening on the free surface of the body, the mamma is developed from the deep cells of the epidermis by a process of continuously progressive ingrowing gemmation, with differentiation. (Fig. 1.) The process begins at about

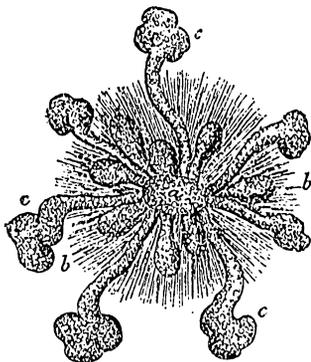

FIG. 1.

(After Weidensheim.)

the third or fourth month of intra-uterine life by certain of the columnar cells of the Malpighian stratum in the site of the future organ, proliferating more rapidly than those adjacent. (SM.) A solid knob-shaped mass of proliferous epithelial cells ingrowing into the subjacent dermis is the result (primary epithelial deposit). About this knob the small, round-celled, embryonic parablatic tissue aggregates and forms a zone from which the nipple is subsequently developed (nipple zone). A few weeks later, by repetition of the initial process, secondary buds arise from the primary ingrowth and likewise grow into the adjacent structures as solid cellular plugs (secondary epithelial deposit). These form the first rudiments of the ducts and lobes, and it is only subsequently that they become excavated. At this stage the nascent gland

FIG. 2.

(After Langer.)

consists of a single branching system of proliferous epithelial cells ingrowing into the surrounding tissues. In the dermis, beneath the nipple zone, there now becomes differentiated a fresh zone of embryonic parablatic tissue, from which the stroma of the gland is developed (stroma zone). In the next stage the primary epithelial ingrowth undergoes retrogressive metamorphosis, often with a certain amount of cornification, and these changes eventually lead to its complete disappearance. At the same time the secondary epithelial ingrowths undergo further development: they become hollowed out and give off numerous club-shaped buds at their extremities—the rudimentary lobules.

In connexion with these small aggregations of irregularly shaped epithelial cells subsequently appear, which constitute the matrix for the development of the true secreting glandular parenchyma—the acini. Towards the end of intra-uterine life each lobe has developed a single external opening or duct.

At birth the organ consists of from fifteen to twenty lobes, the excretory ducts of which are excavated and lined with a single layer of small cubical cells, the rest of the organ being still solid. (Fig. 2.) "In newly born children," says Langer,<sup>6</sup> "we rarely find anything more than the principal ducts, with some indications of ramification in the form of two or three club-shaped processes; and even if these be somewhat more developed, the terminal vesicles are always absent, even in those cases where fluid is secreted." This description has hitherto been generally accepted, but, according to De Sinéty,<sup>7</sup> it is true only for stillborn children and for those who have died shortly after birth. He says that during the first ten days of extra-uterine life considerable formative changes take place in the gland, so that if it be examined at the end of this period some acinous tissue will usually be found resembling that of the adult female mamma during lactation and capable under certain conditions of secreting milk. These changes occur in both sexes and Variot<sup>8</sup> describes them as attaining their maximum between the eighth and fifteenth days after birth. The male mamma being functionally inactive continue in this imperfectly developed condition throughout life, although they generally manifest some temporary disturbance at puberty. In females remarkable structural changes set in at this period, but it is not until after conception that the organ attains its full development. Before puberty the female breast consists chiefly of excretory ducts, but as this period approaches the true secreting structure arises by the abundant new formation of glandular acini. This wonderful post-embryonic transformation is brought about by progressive gemmation, in the same way as the initial embryonic development, of which it is but a superinduced repetition. This demonstrates that between embryonic and post-embryonic developmental processes there are no differences other than those of degree. In the words of Paget, "it is one and the same power which, being maintained continuously from the germ to the latest period of life, determines all organic formation." The commencement of this mammary rejuvenescence usually precedes the first catamenial period, and at every subsequent period more or less temporary sympathetic reaction is excited. But the most important changes are those induced by the stimulus of conception, which converts the previously functionless structure into an active milk-secreting gland. During this period the acini attain their highest degree of structural perfection. This, however, is but a transitory condition which ceases after a time, when the stimulus is withdrawn, and is again renewed on its repetition. During the intervals between these periods the breast remains in a functionless resting state.

These and many other similar facts show that normal tissues may remain quiescent for long periods, and then suddenly take on new phases of growth and development. In this way, then, the whole organ is gradually evolved from the columnar cells of the epidermis. A gland in its simplest form is merely a modification of a single epithelial cell; and according to Goodsir<sup>9</sup> each acinus of the more complex glands consists at first of but a single epithelial cell. It seems not improbable that the initial germ of the mammary gland itself may be of this simple nature. This account of the ontogeny of the breast is chiefly after Rein, Bowlby, Hüss, Kölliker, and Langer. Creighton<sup>10</sup> has given a very different description of the process. According to him the development of the mammary acini is step for step the same as that of the fat lobules, and the ducts arise from the same parablatic matrix; therefore the homologue of the mamma is not a cutaneous gland, but a "fat body." These heterodox views have not been confirmed by subsequent observers—e.g., Rein and Bowlby.

SECTION III.—ONTOGENY AND PHYLOGENY OF THE NIPPLE.

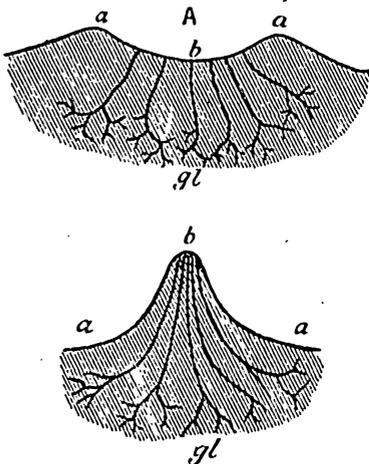

The nipples (*mammillæ*)—papilla-like outgrowths adapted for being sucked—do not develop until after the glandular

<sup>6</sup> Stricker's Histology, Sydenham Society's Transactions, vol. ii., p. 281, 1873.  
<sup>7</sup> Recherches sur la Mammelle des Enfants Nouveau-nés, Archives de Physiologie, p. 293, 1875.  
<sup>8</sup> Gazette Médicale de Paris, Oct. 4th, 1860: Remarques sur la Sécrétion Lactée chez les Nouveau-nés.  
<sup>9</sup> Anatomical Memoirs, vol. ii., p. 422, 1863.  
<sup>10</sup> Journal of Anatomy, vol. xi., p. 1; also Physiology and Pathology of the Breast, p. 33, 1873.

elements have been formed and sometimes they never arise. These ontogenetical phenomena are of great interest from the standpoint of phylogeny, because the lowest mammals—the monotremata—have no nipples. In them the milk simply emerges by numerous ducts through a sieve-like perforated patch of the abdominal skin, from which the young animals have to lick it. These ducts open either on a flat surface (ornithorhynchus) or into a pouch of the integument (echidna). From this it may be inferred—inasmuch as the ontogeny of organs generally represents and accords with their phylogeny—that our mammalian progenitors had no nipples, though they had the glands.

The marsupials differ from the monotremata in possessing nipples. According to Darwin<sup>11</sup> these structures were first acquired by marsupials after they had diverged from and risen above the monotremata, and were by them transmitted to the placental mammals. In human beings at an early stage of development the site where the nipple will subsequently appear is marked by a depression, towards the bottom of which the ducts of the gland converge (Fig. 3, a). Owing

FIG. 3

(After Gegenbauer.)

to arrest of development at an early stage this rudimentary state may persist throughout life and such malformations are met with both in the normally placed and in the supernumerary nipples. They remind us of the mammary pouch of Echidna. The further development of the nipple is effected by the area of skin, perforated by the ducts, being raised up into the form of a papilla, above the level of the rest of the integument (Fig. 3, b). When the whole of the cutaneous area perforated by the ducts of the nascent gland is not integrated with the developing nipple, then such of the ducts as are left behind, instead of opening on the summit of the nipple, do so on the areola, where they are to be found chiefly about the base of the nipple. Thus the so-called glands of Montgomery (*glandulae lactiferæ aberrantes*) arise. From the frequency of these and other somewhat similar malformations we may conclude that the mammae, like the lacrymal and salivary glands, are normally very imperfectly integrated organs. At birth the nipples are fairly prominent in both sexes. Their ducts generally contain disintegrating epithelial cells which sometimes deliquesce into a milk-like fluid.

Preston.

VICTORIA DENTAL HOSPITAL, MANCHESTER.—On the 27th ult. the distribution of prizes in connexion with this hospital took place at the Grand Hotel. The report for the eighth year of the institution showed that the present year seemed likely to prove an important one in the history of both the hospital and the dental school, inasmuch as the institution would shortly be established in the new and large premises, but which would only be temporarily utilised pending the building of the new hospital. The committee had recently drawn up a graduated scheme of instruction in operative dentistry which they believed to be more thorough and systematic than any at present in use at other dental hospitals in the kingdom.<sup>14</sup>

## ON MISSED ABORTION: WITH NOTES OF THREE TYPICAL CASES.

BY ARTHUR H. N. LEWERS, M.D., M.R.C.P. LOND.,  
OBSTETRIC PHYSICIAN TO THE LONDON HOSPITAL.

CASES of missed abortion are by no means uncommon; they are easily recognised if the possibility of the existence of the condition is kept in mind and proficiency has been acquired in the bimanual method of examination, especially so far as concerns the determination of the size of the uterus. Yet comparatively little prominence has been given to the subject by the majority of writers on gynaecology, with the notable exception of Dr. Matthews Duncan, whose classical lecture on Missed Abortion first led me to recognise cases of the kind. The history is usually of great importance. In most cases the patient, having been previously regular, misses one or more periods, and, especially if more than one period has been missed, most probably believes herself to be pregnant. If it should happen at this time that the medical attendant is called on to make an examination, the size of the uterus as determined by him may be of much value in making the diagnosis when other symptoms arise later on. We have, then, to begin with, an interval of amenorrhœa accompanied by the other symptoms and signs of early pregnancy. Generally the first indication of there being anything unusual in the case is the occurrence of hæmorrhage, usually at first slight and intermittent, the intervals between the losses being days or weeks; or it may be that there is a constant, blood-stained discharge, the proportion of blood varying from time to time. It is usually on account of this hæmorrhage that the patient seeks advice. It is obvious how valuable a previous examination of the patient may now prove, if a month or more has elapsed since the previous examination; for it may be found that the size of the uterus has remained stationary or has even somewhat diminished. It often happens, however, that we have no previous examination to guide us, and then it is best to compare the size of the uterus when the case is first seen with the size it should have been had the pregnancy been a normal one, reckoning from the beginning of the interval of amenorrhœa. The treatment depends on the amount or persistence of the hæmorrhage. In some cases bleeding is considerable till pains come on leading to the spontaneous expulsion of the ovum; the first case recorded below is an example of this class. In other cases bleeding is often rather free from time to time, and may be continued over a long period without the uterus showing any tendency to discharge its contents. In the second case described bleeding had lasted three months. In such cases the right treatment is to dilate the cervix and clear out the uterus. Hegar's dilators are particularly well suited for effecting the necessary dilatation, for the cervix is soft and readily dilates in a few minutes, without laceration, to the size of No. 20. Rapid dilatation is also to be preferred for another reason. The slightest disturbance of the contents of the uterus (such as is unavoidable when either a tent or one of Hegar's bougies is passed beyond the internal os) will often set up very free hæmorrhage. An instance of this is recorded in Dr. Matthews Duncan's lecture already referred to: "On the introduction of the tent, hæmorrhage began suddenly and proceeded to an alarming extent, two pints being the quantity estimated as lost within fifteen minutes," &c. Here, as in ordinary cases of post-partum hæmorrhage, it is to tonic contraction of the uterus we must look for the permanent cessation of the hæmorrhage. This contraction cannot occur till after the removal of the ovum; hence the advantage of that method of dilatation which renders the ovum accessible in a very few minutes. After the uterus has been emptied I usually swab out the endometrium with pure tincture of iodine, and then wash out the uterus with a hot douche of iodine water (one or two drachms of the tincture of iodine to a pint of hot water). Subsequently the patient has vaginal douches of iodine water for a week, and I am in the habit of ordering some preparation of ergot to be taken for two weeks after the operation. Cases treated in this way do exceedingly well. The following notes refer to three typical cases of missed abortion recently under my care.

CASE 1.—Mrs. H—, multipara, was seen on Oct. 2nd,

1891, desiring to know if she was pregnant. Her last confinement occurred on June 15th, 1890, and she was ill for some three or four months afterwards with phlegmasia dolens. She had not menstruated since the first week of July, 1891. On examination the size of the uterus indicated that she was a little more than three months pregnant. I saw her again on Jan. 4th, 1892, owing to there having been some slight hæmorrhage. *Although it was almost exactly three months since the previous examination, the uterus was little, if at all, larger than it had been then.* As the bleeding had only been slight, she was advised merely to keep quiet and send again if necessary. On Jan. 16th I was sent for to see her about 10.30 A.M., as pain and bleeding had come on during the night. On examination the os was found to be a good deal dilated, and the ovum projecting through. As there was no bleeding at the time, a hot vaginal douche of iodine water was given and the vagina packed with carbolised gauze. At 6 P.M. the gauze was removed and almost the whole ovum was found in the vagina. The fœtus was the size corresponding to a pregnancy of three months and a half. It was macerated, but not in the least putrid. The patient's subsequent progress was quite satisfactory.

CASE 2.—Mrs. S.—, a multipara aged forty-one, was seen in consultation on Jan. 15th, 1892. The history was that she had been losing blood nearly every day for the previous three months. Before that she had "seen nothing" for three months and believed herself to be three months pregnant. On examination the uterus was about the size corresponding to three months' pregnancy. The os uteri was somewhat patulous and blood was coming from it. As the patient was markedly anæmic, rapid dilatation of the cervix was recommended and agreed upon. Accordingly on Jan. 17th the cervix was rapidly dilated to the size of No. 20 (Hegar). Smart hæmorrhage occurred directly the first bougie was passed. When the finger was passed into the uterus a fleshy, firm mass was felt attached above, but lying loose at its lower part, and, as it were, flapping about in the relaxed uterus. It was removed partly with the finger and partly with polypus forceps. Bleeding was stopped by washing out the uterus with hot iodine water and by mopping the endometrium with pure tincture of iodine. The mass removed had a flattened, ovoid shape. On section it was found to have a central cavity lined by smooth membrane, but there was no trace of a fœtus. The wall of the cavity was composed of a firm placenta-like tissue, and was from a quarter to half an inch thick. The patient made an uninterrupted recovery. It will be seen that on Jan. 15th the uterus should have been the size corresponding to six months' pregnancy, but it was, in fact, only the size of the pregnant uterus at the end of the third month.

CASE 3.—Mrs. B.—, aged thirty-eight, a multipara, was seen on Jan. 26th, 1892, with the following history. The last confinement had occurred about three years previously. She had been regular up to the middle of September, 1891. She did not menstruate in October, but during November a slight "show" of blood, lasting only a few hours, was seen on two or three occasions. Bleeding came on again about Jan. 5th, and had continued daily till Jan. 26th, clots being passed on several occasions, but she had had no labour pains. On examination the uterus was found to be rather smaller than the pregnant uterus at the end of the third month, and it had the usual characters of the pregnant uterus at that time. The patient, however, did not believe herself to be pregnant. A diagnosis of missed abortion (or mole) was made. Had the pregnancy been a normal one the uterus should have been nearly up to the level of the umbilicus, but nothing of it could, in fact, be felt by palpation of the abdomen alone. She had been taking a mixture containing ergot for a few days before I saw her. The cervix was rapidly dilated on Jan. 27th and the ovum removed, the various procedures being the same as those adopted in Case 2. In this case, however, there was a fœtus of about ten weeks' development; it was macerated, but not putrid. The patient subsequently did well.

Wimpole-street, W.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The following candidates passed the examination of proficiency in Psychological Medicine at Bethlem Hospital on July 7th and were awarded the certificate:—Frank Belben, E. Milliken Goldie, W. A. Inslam, R. J. Hutchinson, Robert H. Lloyd, J. H. Sprout and W. P. Umney. Dr. George M. Robertson obtained the medal and prize of ten guineas for the best essay, and Drs. Nathan Raw and George R. Wilson were bracketed equal for the Gaskell Prize.

## Clinical Notes :

### MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL.

#### UNUSUAL EFFECTS FROM THE USE OF ATROPINE AND HOMATROPINE EYE-DROPS IN INFANTS.

By GEORGE CARPENTER, M.D. LOND., M.R.C.P.,  
SENIOR PHYSICIAN TO OUT-PATIENTS TO THE EVELINA HOSPITAL FOR SICK CHILDREN.

THAT children bear belladonna well and much better than adults is an established fact, and that they can absorb large doses of the drug without physiological reaction is sufficiently recognised. Like everything else, however, there is a *but* attached to the above statements, and as the result of my clinical observations that "but" is as follows. For some years now it has been my practice to make free use of the ophthalmoscope for diagnostic and other purposes. The combination of a pin-point pupil, a roving eye, a screaming infant and a large out-patient clinique not being conducive to rapid ophthalmoscopic examinations, I have been frequently compelled to make use of atropine or homatropine to facilitate matters. It is quite agreed that dilatation of the pupils is one of the most characteristic symptoms of belladonna. Ringer says he has often given to children two or three years old as much as ten minims of the tincture every hour, and this quantity usually produces no effect, neither dilating the pupil nor making the throat dry. The only symptom he has ever noticed from these large doses is dilatation of the pupil. With these remarks I cordially agree.

As the result of my observations on young infants I find :  
1. The pupil not infrequently in infants' remains for a long time undilated, sometimes for hours. The reaction is often tardy, and then the pupil may not dilate to its full extent. This is quite apart from iritis, iritic adhesions, or what not. 2. Physiological symptoms in infants not seldom occur; whether from absorption by the ocular conjunctiva or passage down the lacrymal duct and so on, I am not prepared to state—possibly both causes are in operation.

In support of these statements I give the following instances as examples, but I have met with more than these cases.

CASE 1.—T. M.—, aged three months, a congenital syphilitic suffering from double congenital cataract. When atropine drops were put in his eyes he soon afterwards flushed. His mother said the features became swollen, the breathing seemed to be stopped and he remained in a distressed condition for the rest of the day. The pupils did not dilate at all satisfactorily.

CASE 2.—H. S.—, aged two months, a congenital syphilitic affected with rickets, attended on March 28th, 1889. On June 3rd he had two applications of atropine to the eyes; the pupils did not dilate. He developed a bright-red flush and gaped. On June 17th several applications of atropine were made to the eyes, but the pupils refused to dilate to more than half their extent. The child became considerably flushed both as to his eyes, face and chest. The mouth, though moist, was drier than usual. His mother said that he slept very heavily for about an hour. There is a note on July 1st to the effect that the pupils were much dilated for three days and did not become so until two days after the application of the drops.

CASE 3.—A. H.—, aged seven months, a congenital syphilitic; proptosis dating from birth. The nystagmus was chiefly to the right; there were no fundal changes and no iritis. The pupils took a very long time to dilate at all, and then they were not large.

CASE 4.—M. A. M.—, aged four months, a congenital syphilitic. Homatropine drops were used in order to examine the fundi. Shortly afterwards the child became flushed and drowsy. There were no changes in the fundi or traces of old iritis.

Exception may be taken to my first conclusion on the ground that the cases I quote were syphilitic; *ergo*, iritis or iritic adhesions were in action. My reply to that is: Putting aside the rarity of iritis in infantile congenital syphilitics in my experience, from systematic observation in a large number of such cases, they presented neither iritis

1 I have not noticed these effects in those over one year of age.

nor iritic adhesions to focal or ophthalmoscopic examination. Moreover, I think that assumption is quite out of court, for I have noticed it in others not syphilitic. As regards my second, a too liberal allowance of drops may be suggested. Putting aside the fact that the phenomena narrated soon supervened they had no larger quantity—and possibly less from the difficulties attendant—than older children who show no such symptoms. The atropine drops contained 1 per cent. or four grains to the ounce; the homatropine drops also contained 1 per cent. or four grains to the ounce.

St. Ermin's Mansions, S.W.

#### PNEUMONIA SUCCESSFULLY TREATED BY BRIN'S OXYGEN.

BY ROBERT WATERING BATEMAN, M.R.C.S., L.S.A.

I SEND the following note for publication in THE LANCET, as I believe I am right in saying that this case is among the first treated by Brin's oxygen, as suggested and carried out by Dr. Lauder Brunton in the case of a clergyman in London.

Mrs. W—, aged sixty-three. I was called in whilst on my rounds on Jan. 31st of the present year to see this lady, and found her suffering from the prevailing epidemic (influenza), with a temperature of 103°. After administering quinine the temperature came down, and all the influenza symptoms were subsiding until Feb. 6th, when pneumonia of the left base appeared, the temperature going up again to 102° and the breathing to 36. Consolidation appeared next at the right apex behind; and, the patient becoming in a very dangerous state, I called Dr. Image of Bury St. Edmunds in consultation, and he advised Brin's oxygen. On administering the oxygen on the following day it was remarkable how the cyanosis disappeared after five minutes' inhalation. The inhalation was kept up for ten minutes the first time and given for a longer period subsequently. After that the oxygen was given twice daily, twenty minutes' inhalation at a time, until March 25th. The effect of the oxygen was very marked: after one administration, when at her worst, the patient remarked that it made her feel quite hungry. It always removed the cyanosis, refreshed her, and kept her going. The apex of the right lung commenced to clear first and then the left base, until March 5th, when they were quite well. The administration of the oxygen was continued afterwards, as the convalescence was extremely slow, and it always did her good. There is one thing which ought to be well borne in mind—viz., that inflammations following epidemic influenza are of a very ataxic character and require free stimulation; for drugs, ether, ammonia and senega are the most useful, hyoscyamus when the cough is very troublesome. A good jacket poultice wrapped round the aching inflamed lung is the best local application, and it is best to put the water in the basin first and then add the linseed, stirring the while to make the poultice. The nurses I had from London last winter almost invariably made them in the opposite manner at first, making a lumpy poultice; whilst the other way, putting the hot water in first and then adding the linseed, makes the poultice of an even consistence. There is another matter to be noticed in the pneumonia of influenza—viz., the erratic character of the inflammation. Commencing in one part—say, the base of one lung—it jumps, so to speak, right over to the other lung, and attacks perhaps the apex. There is no doubt that the influenza germ poisons the lungs, and it being erratic in its general behaviour may perhaps explain its attacking different portions of the lungs. In giving the gas it is best, when the valve has been turned on, to allow it to stream into the mouth direct, and not fill the bag which is in connexion with the tubes. It is a good thing to paint the chest with iodine liniment when the poultices are left off.

Wickhambrook, Newmarket.

#### A CASE OF INFANTILE LACTATION.

BY J. HILTON THOMPSON, M.D. VICT.,

LATE SENIOR RESIDENT MEDICAL OFFICER IN THE CHILDREN'S HOSPITAL, PENDLEBURY.

THE following case is of interest if only on account of its rarity. A healthy, well-developed male child, born at full term, showed about fourteen days after birth well-marked

swelling of the mammary glands. The skin over the glands was congested; on pressure a thin, yellowish, milky fluid escaped drop by drop from the nipples. About two days after the condition was noticed a small, badly defined hardness could be felt in the left breast external to the nipple; moderate pressure caused no pain; the hardness remained for two days, gradually becoming less manifest. Lactation ceased in the right breast in five days and two days afterwards in the left. The general condition of the infant appeared to be unaffected.

Bolton, Lancashire.

#### CASE OF SWALLOWING FISHBONES.

BY J. R. WHITE, M.B.

ON March 8th last I was requested to attend Mr. D—, and on arrival found him in bed complaining of some abdominal pain and also considerable thirst and retching; the temperature and pulse were, however, normal, but the tongue was coated. The history which he gave was that about a month previously he was partaking of fish in company with his wife, when suddenly a somewhat large piece of fishbone slipped down his throat. He immediately rose from the table, and, feeling choked, endeavoured to eject the offending substance, but without success, and it eventually passed into the stomach. Since the date of the occurrence he had not felt much inconvenience, but occasionally suffered from pain in the bowels and also found he could not exert himself or stoop much without causing pain. At last, as the pain got somewhat worse and sickness commenced, he sent for me. The symptoms daily increased in severity. The pulse rose to 120, also the temperature three or four degrees. The vomiting became constant and was accompanied by purging; there were also pain and tenderness in the abdomen, especially in the ileo-cæcal region, and considerable perityphilitis; the stools were of a typhoid character. The case was one in which the symptoms of gastro-enteritis and typhoid fever were closely combined. I had the advantage of the assistance of Dr. Frederick Carter in consultation. In about a week several pieces of fishbone were passed per anum; the largest was a piece of the backbone about an inch long, with spines attached. Amelioration of the symptoms at once began, convalescence being established in a couple of weeks. A sequel which I consider of interest in this case is that the patient was insured in an accident company and claimed compensation for the accident which he had met with, which he obtained.

Grays, Essex.

#### PYROGALLIC ACID.

BY U. BANERJI, M.R.C.S., L.R.C.P. LOND.

ON May 15th last at about 3.30 P.M. two patients, husband and wife, took pyrogallic acid. From the statement of the husband and from the appearance of the bottle I consider that much more than a drachm of the acid was taken by each. The man told me that he swallowed two handfuls of the poison. On arriving at the house at 4 P.M. I found the male patient under the influence of liquor, and taking a bath under a water-tap. I administered an emetic to each, mustard and hot water. The male vomited, but the female did not. The vomit appeared to consist of water, mustard, mucus and a white matter looking like pyrogallic acid which I at the time held in my hand. Finding that the patient did not complain of anything, I simply ordered twenty drops of dilute nitro-muriatic acid to be taken every two hours, and at night six ounces of olive oil to be taken in three equal doses. Next morning (the 16th) I found the patients in their usual good health, but in both cases the tongue was stained deep black. The urine and stools passed over-night were quite normal. I did not order any medicine. On the 17th I took the following notes from the male patient (the female, I might have mentioned, never complained of anything abnormal): "Sensation of drowsiness coming on at intervals; the patient likens it to that produced by opium. There is nausea, but no vomiting; slight paroxysmal numbness about the extremities and face; slight palpitation and dryness of the throat; tongue moist, still black; no abnormal sensation in the abdomen; passed a natural stool in the morning; heart sounds normal; pulse 62 in the minute; urine normal; perspiration rather scanty;

no headache; slept well." Since the above date the patients have been continuing in their usual good health. No one was present to see the acid actually swallowed, but the patients said that they took it in handfuls. The bottle which contained the acid was as large as a Howard's quinine phial; two-thirds of its contents had disappeared. In the *Medical Record* (page 49) a case is recorded in which a patient suffering from psoriasis was poisoned by pyrogallic ointment applied to one half of his body, whilst to the other half chrysophanic acid ointment was applied for comparison. The difference can be explained only by the supposition that the acid acts differently when applied and when taken internally.

## A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prooemium.

### ST. BARTHOLOMEW'S HOSPITAL.

CASE OF HYSTERICAL PARALYSIS OF THE ABDUCTORS OF  
THE LARYNX AND OF THE DIAPHRAGM, ASSOCIATED  
WITH PECULIAR MOVEMENTS OF THE PALATE.

(Under the care of Dr. S. WEST.)

THE following is an interesting account of a patient suffering from paralysis of most important muscles due to hysteria. It is said, and with reason, that this disease may simulate almost any other known disease; but there are usually certain conditions accompanying it which enable the physician or surgeon to recognise the origin of the trouble. Here "the very irregularity of the affection" enabled the physician to come to a correct diagnosis. Had it not been for the careful examination of the larynx and the instructions based on the conclusion arrived at, it is possible that tracheotomy would have been performed for the urgency of the dyspnoea and a considerable element of danger introduced into the case as a result of the performance of the operation. The onset of bronchitis or of pneumonia might have proved fatal where the diaphragm was already paralysed.

The patient, a woman aged thirty-eight, was admitted into the hospital on account of dyspnoea. She stated that she had been in her usual health until Christmas time, when she was attacked with bronchitis, from which she had suffered once or twice before during the last three years. She had had a cough, but her breathing had not become difficult until a week before admission, in the middle of February. The patient was of medium height and well nourished. She was evidently suffering from dyspnoea, for the breathing was laboured and somewhat hurried, the *alae nasi* dilating, the face flushed, but without much cyanosis. The movements of the chest were peculiar, the breathing being entirely with the upper parts; the diaphragm was apparently paralysed, for it did not descend at all on inspiration; and the abdomen, instead of being made prominent by inspiration, was retracted, as if the diaphragm was sucked up into the thorax, the lower intercostal spaces and the lower ribs being at the same time drawn in, as were also the supra-clavicular and episternal spaces; the larynx remained fixed and showed no respiratory excursion. On auscultation nothing was to be heard out of the normal except a little wheezing. Inspiration was rather noisy, evidently owing to laryngeal stridor.

On examining the throat the movements of the palate were seen to be extreme, but of a peculiar kind, for on expiration it was raised with considerable violence as high as it could be, becoming on expiration quite flaccid, and falling down as if suddenly paralysed. The vocal cords, on laryngoscopic examination, were found to be in close approximation and separated by a chink not wider than half a line during inspiration, while on expiration they separated and assumed the cadaveric position. The cords themselves were quite white, though the patient spoke with a hoarse voice. As

already stated, there was no respiratory excursion of the larynx at all, in spite of the laryngeal obstruction. The arytenoid cartilages did not move towards the middle line on inspiration, when the cords approximated, so that at that time a triangular chink was left in the posterior part of the glottis; on phonation, however, they moved freely towards each other and took their proper place. The condition of the larynx was clearly this, that the abductors were completely paralysed. Of the glottis closers the crico-arytenoidei laterales contracted on inspiration, possibly alone or in conjunction with the crico-arytenoidei to some extent. The arytenoidei postici and obliqui were not paralysed, for on phonation they contracted, bringing the arytenoid cartilages into approximation, though as the voice was hoarse it is probable that their contraction was not perfect, and the same was the case with the crico-arytenoid. The action of the larynx was to a great extent perverted, as was that also of the palate, while the diaphragm was paralysed. The very irregularity of the affection suggested the correct diagnosis—viz., that of hysteria. This diagnosis was supported by the history obtained from the patient, that at the age of twenty-three she had suffered from a contraction of the throat and neck, so that she could not open her mouth, on account of which her front teeth were drawn and she was fed for some weeks by means of a stomach pump. The patient was now put under chloroform, but without any relief to the breathing. Perhaps she was not completely anaesthetised, for the breathing became unsatisfactory, and it did not seem prudent to push the chloroform further. Having formed the opinion that the affection was hysterical, Dr. West's instructions were given that the patient was on no account to be tracheotomised, but that if the dyspnoea became urgent intubation should be performed. This was done two days later, but without much success, for the tube was not long retained in position.

The interrupted current was then applied two or three times during the next two days externally to the larynx. The condition remained much the same until the 22nd, when it was found that the arytenoid cartilages moved on inspiration about half way towards the middle line, thus increasing the dyspnoea somewhat. The breathing had from her admission been noticed to be much quieter during sleep. The patient was able to take solid food, but vomited at irregular times after taking it.

On the 26th, on examination in the morning, the condition was the same, but about mid-day it suddenly changed and the breathing became perfectly quiet. The diaphragm moved naturally, though not freely; the palate ceased to move at all on inspiration. The vocal cords occupied their normal position on quiet respiration and on deep inspiration separated widely as they ought to do; and it was observed that they were in constant oscillation, as if uncertain what exactly to do, sometimes being somewhat approximated and sometimes extremely retracted. On phonation the movements were natural, though approximation seemed to be hardly complete, for the cords were not quite tense enough; and from this cause, as well as from a little laryngitis, the result of the intubation, the voice was still husky. The interrupted current had been used daily and the patient objected greatly to its application. On the 29th the approximation of the cords had returned, though not quite to the same extent as at first and there was but little dyspnoea. On expiration, however, the cords did not recede more than a little and could not reach the cadaveric position by a long way. The same uncertainty about the contractions was evident, which was previously observed, so that on no two consecutive respirations were the positions exactly the same. The palate was stationary and the diaphragm moved now and then, but seemed to be equally uncertain what to do. This condition remained much the same whenever examination was made until March 2nd, and then during the application of the battery to the abdomen the action of the diaphragm became normal, and on applying it to the larynx, and making the patient speak, the voice became quite clear, and both breathing and speaking remained natural till March 4th. On that morning the symptoms had returned, but an application of the battery caused their prompt disappearance, and at Dr. West's visit in the afternoon he found the diaphragm and palate acting naturally, but the action of the cords was peculiar, the uncertainty of their movements being greatly exaggerated—in fact, almost choracic—on quiet respiration, though deep inspiration steadied them for the time, as did phonation also. Phonation, however, appeared to be perfect, for the voice was clear and steady.

The patient, having a great dislike to the battery, and being otherwise not content, declined to remain longer in the hospital. A fortnight later she was admitted in the same condition, and was afterwards sent to a convalescent home. Altogether she was under observation for nearly three months. The symptoms varied from time to time, and often were entirely absent, but when they occurred they were the same as described above, except that the paralysis of the diaphragm and the perverted movements of the palate were never again so marked.

### GENERAL HOSPITAL, BIRMINGHAM.

#### A SERIES OF CASES OF CONGENITAL MALFORMATION OF THE LARGE INTESTINE; REMARKS.

(Under the care of Mr. GEORGE HEATON.)

WE published in the last issue of THE LANCET, p. 257, the first two cases of this series. Case 1 was an example of imperforate anus with probable absence of rectum and descending colon; an artificial anus was made in the left groin and the patient lived six weeks; no post-mortem examination could be obtained. Case 2 was one of imperforate rectum, with penile fecal fistula. After incision the mucous membrane of the bowel was brought down and sutured to the skin. The child recovered and was quite well when last seen some months after operation. We would refer our readers to the remarks by Mr. Heaton.

**CASE 3.** *Imperforate anus, with malformation of the large intestine.*—This patient was sent for examination by Dr. Purslow, who kindly allowed the case to be reported. The child, a male one, lived only a few hours, and was the subject also of a double talipes equino-varus, extroversion of the bladder and a parasitic foetus attached to the dorsal spine. On making an examination, a large pouch was found situated in the middle line behind and projecting externally below the attached foetus. The small intestines were natural, but several coils were contained in this hernial sac. The cæcum was fixed centrally to the posterior wall of the sac and from it the large intestine passed vertically downwards and entered the rectum in the middle line over the lumbo-sacral promontory. The ascending, transverse, descending and sigmoid colon were thus represented by a piece of large intestine two inches and a half long and both loins were empty of large intestine. The rectum itself ended about two inches from the skin of the anus in a dilated pouch. Passing from this pouch along the back of the bladder to the anus was a dense fibrous band. Externally there was a slight depression marking the situation of the anus. The tuberosities of the ischium were very closely approximated. The other deformities do not need description here.

**CASE 4.** *Imperforate anus with vaginal fecal fistula.*—A. X—, aged seven days, was admitted into the General Hospital on May 20th last with a history of having passed all her motions through the vagina since birth. An examination showed the anus to be absent, no depression or marking of the skin being present to indicate its position. The labia majora and minora were swollen, tender and covered with an acute eczematous rash. On straining or crying yellow fecal matter escaped from the vulva. Chloroform was given and an examination made. On drawing the labia minora apart the orifice of a fecal fistula was seen, situated posteriorly in the middle line just at the attachment of the hymen. A bent probe was passed through this into the rectum and made to project in the perineum. This was cut down upon and a free opening made into the dilated rectum. The mucous membrane of the bowel was brought down without difficulty and stitched to the edges of the skin incision. The eczema quickly disappeared from the vulva and faeces were discharged normally through the anus. The child left the hospital on June 11th owing to measles, but is to return later to have the fistula closed.

**CASE 5.**—This case is interesting as illustrating an arrest of the cæcum in its passage from the umbilical region into the right iliac fossa. R. M— was admitted into the General Hospital on Aug. 18th, 1890, four hours after birth. The infant was a well-formed female child. Protruding from the umbilical region was a membranous sac about the size of a large orange, with walls,—thin and transparent in most of their extent, but thickened on the right side, where the umbilical cord entered. The intestinal coils could be plainly

seen through the sac walls. Taxis utterly failed to reduce any of the contents. Two hours after admission the child was given chloroform. The sac and abdominal wall were freely laid open by a vertical incision, and the contents partly reduced into the abdominal cavity. Several coils of small intestine, one with the remnants of Meckel's diverticulum attaching it to the sac wall, were reduced. The cæcum and vermiform appendix were also present in the sac, and reduced after some difficulty, owing to their adherence to the sac wall. The line between sac and skin was well defined externally, but internally the membranous sac was lined for about an inch by a vascular velvety membrane. It was to this membrane that the cæcum was adherent. The sac, with the attached umbilical cord, was cut away and the opening closed with silk sutures.

Aug. 19th.—The child vomited "coffee-ground" matter all that evening, and throughout the night. The vomiting continued at intervals during the day. At 4 P.M., as no urine or meconium had been passed, a small catheter was passed and urine drawn off. The anus was then examined and thoroughly dilated with dressing forceps. This gave vent to a large quantity of meconium. The vomiting ceased from that time and the child rapidly convalesced. The remnant of the umbilical cord separated on August 24th and the child was sent home with the wound soundly healed on August 31st. She has been seen lately, eighteen months after, and is a strong healthy girl. She has never since leaving the hospital had any intestinal trouble.

*Remarks by Mr. HEATON.*—In Cases 1 and 3 it was not possible to find the rectum through an incision in the perineum—in Case 3 certainly, and I feel sure also in Case 1, though post-mortem evidence was not obtainable in this case, both the ascending and descending colon were absent from their normal situations. The question of colotomy, in cases where the rectum cannot be reached through an exploratory incision in the perineum has been ably discussed by M.M. Huguier and Robert, and by Mr. Marrant Baker. Amussat's operation in the loin is open to the objections that the space is extremely limited, the distance between the iliac crest and the lower ribs being in these cases very small and that the thickness of subcutaneous fat makes the wound a very deep one. Again, the descending colon is frequently at such an age attached by a complete meso-colon, and the risk of opening the peritoneal cavity is thus considerably increased. M. Huguier, in his paper on the subject, advocated a colotomy in the right loin. He had noticed that in cases of complete absence of the rectum, the descending colon frequently took a sharp bend to the right and ended to the right side of the middle line. In such cases the operation would undoubtedly be simpler on the right than on the left side. But presuming both ascending and descending colon to be present in their normal positions, as they are in the majority of such cases as far as I can gather from an examination of museum specimens, it seems unreasonable to operate on the right, expecting to find the abnormal rather than first of all to look for the descending colon in its normal position. In Case 1 a diligent search in the left inguinal region failed to find the colon and the exhausted condition of the patient rendered it unadvisable to make a second exploratory incision on the opposite side. In future in a case where a careful perineal exploration failed to find the rectum I should be disposed to make a small median abdominal incision. The iliac fossæ could then be explored and the position of the colon ascertained, then a left or right inguinal colotomy could be performed, as the case might be, and the original wound closed. In the rare event of failure to find any large intestine, the exploratory incision could be converted into an artificial anus by bringing up a distended coil of small intestine and opening it *in situ*. Case 2, in which together with an imperforate rectum there existed a fecal fistula at the end of the penis, is a rarity not often met with. The urinary passages were quite separate and perfect. The fusion of the hind gut with the proctodeum had failed to take place and in its stead there existed a long narrow fistula connecting the blind end of the gut with the skin of the penis. Case 4 is a common variety of the deformity, and I have seen two other instances. The fistulous communication is, as a rule, a free one and so the patient does not suffer from intestinal obstruction. In fact cases are on record where the subjects of this deformity have grown up without being aware of there being anything the matter. Attention, however, is usually called to the case by the irritation which the fecal matter sets up in its passage through the vulval outlet. Case 5 is an example of an arrest of the

cæcum in its passage from the umbilical region to the right iliac fossa. Mr. Lockwood has shown that this part of the large intestine, which originally protrudes into the umbilical sac, passes first of all from the umbilical region upwards towards the left hypochondrium. It then passes across the abdomen into the right hypochondrium and finally descends into the right iliac fossa. In this case the cæcum was detained in the umbilical sac, probably owing to intra-uterine peritonitis, of which the florid granulations described as present in the sac are an evidence. This detention would then, of course, prevent the closure of the umbilicus and thus produce the hernial sac. The after-treatment of cases of imperforate anus is of the greatest importance and persevering attention is required for a long time. The tendency of the newly made opening is always to contract and unless kept in check the patients will be left with an extremely troublesome and intractable stricture with all its sequences. In many cases no doubt it is impossible to bring down the mucous membrane of the bowel to the skin without undue tension, but when this can be done I consider it of the greatest importance to get union between it and the edges of the skin incision. In one of my cases I obtained such union all round and in another I was able to get union on one side. Very little contraction of the anal outlet has taken place up to now in either of these cases; and the occasional passage of a small bougie is all that is necessary to counteract this.

## Reviews and Notices of Books.

*Watts' Dictionary of Chemistry.* Revised and entirely Rewritten by H. FORSTER MORLEY, M.A., D.Sc., Fellow of University College, London, and Professor of Chemistry at Queen's College, London; and M. M. PATTISON MUIR, M.A., Fellow and Prælector in Chemistry of Gonville and Caius College, Cambridge. Assisted by eminent contributors. Vol. III. Longmans, Green & Co. 1892.

THE publication of this most important and valuable work proceeds with commendable punctuality, and the new volume, which is larger than either of the first two, is fully equal to them in merit. It will be remembered that, owing to the rapid progress of discovery and the alterations of plan which were found necessary, little has been left beyond the name of the original editor. Almost the whole has been rewritten, and, although the work has been lightened by the exclusion of analytical and applied chemistry—to the last of which a separate dictionary in three volumes has been devoted—the editors have been compelled to use the utmost possible condensation.

As before, the bulk of the work has fallen on the editors, Mr. Pattison Muir taking the inorganic and Dr. Forster Morley the organic portions. Even the slightest examination will show how enormous the labour and how thoroughly conscientious the work of the editors has been. Quotation is next to impossible, for the contractions employed are so numerous that a large proportion of the book is more like a lexicon than a treatise. In regard to all important substances, the greatest pains have been taken in the statement not only of chemical but of physical data. Thus in the article on nitrogen we find an account not only of the formation, preparation, properties and combinations of the element, but also its boiling point as liquid, its specific gravity as gas and liquid, its specific heat, its coefficient of expansion, its absorption, coefficients, its heat of combustion, and many other most important physical constants. A similar example is afforded in the article on naphthaline, which opens with a long string of physical constants. References to original authorities are incessant throughout the volume, and are greatly assisted by a list of abbreviations printed on a book-marker. One of Mr. Muir's best articles is that on "Molecular Weights," in which the important law of Raoult, which states the relation between molecular weight and the lowering of freezing point produced by solution, is clearly stated and illustrated. It forms as it

were an appendix to the articles on atomic and molecular weights in vol. i.

The following special contributors have assisted the editors:—Professor H. E. Armstrong ("Isomerism"), Mr. Carnegie ("Periodic Law"), Mr. Crookes ("Rare Metals"), Mr. C. F. Cross ("Lignone"), Mr. Fletcher ("Mineralogical Chemistry"), Professor Halliburton ("Milk and Muscle"), Professor Huntington ("Metallurgical Chemistry"), Dr. Hutchinson ("Isomorphism"), Professor Japp ("Ketones and Lepidine"), Dr. Rideal ("Paraffin and Petroleum"), Mr. Shenstone ("Ozone"), Professor Tilden ("Pentinen"), Professor J. J. Thomson ("Molecular Constitution of Bodies"). It is evident that in many cases no other authors equally suitable could have been chosen for the articles. Thus, for example, what other chemist could have written on "Rare Metals" with authority equal to that of Mr. Crookes? Detailed criticism of a book like this is of course impossible, and a few words on articles likely to be particularly interesting to our readers must suffice. Mr. Cross, who, with his colleague Mr. Bevan, has worked more than anyone else in this branch of research, has contributed under the heading of "Lignone" a very valuable history of the present state of our knowledge in regard to the process of lignification. It may be regarded as supplementary to the article on Cellulose in vol. i., but it brings the history of discovery well down to the present time. The complex group of carbohydrates is gradually revealing its mysteries in response to the patient labour of chemists. Since the first synthesis of glucose new hopes have grown in the minds of investigators. Many of Dr. Morley's articles—for example, those on Lactic Acid and Phenol—will be interesting to physiologists as well as to chemists, especially as some analytical details are given. Professor Halliburton's articles are somewhat sketchy. Doubtless more details will be given in regard to the constituents of muscle in the article on "Proteids," which has not yet appeared.

When these two important dictionaries shall have been completed, or even before that time, we hope the publishers may undertake the preparation of that much needed work, a dictionary of analytical chemistry. It would form a most valuable supplement to the other two.

*Indigestion.* By GEORGE HERSCHELL, M.D. Lond. London: Baillière, Tindall, and Cox. 1892.

THE majority of cases met with in practice are probably those which may be classed under "dyspepsia," and perhaps no subject receives less attention in our medical schools. Cases are so common in the out-patient rooms of hospitals, and the treatment of them is so unsatisfactory, that students give little heed to them, and it is only on entering into practice that the deficiency in knowledge of such an important group of diseases is discovered. On referring to the ordinary textbooks the practitioner will find but a meagre account of the symptoms and treatment of the all-prevailing complaint, indigestion. The volume we are now considering well supplies the want which has been felt for a concise account of this disorder. Seldom have we met with a work better arranged or more easy of reference. The book consists of less than 200 pages, yet in it the reader will find a very fairly complete account of the subject. The first chapter is preliminary and treats of the process of normal digestion, an intimate knowledge of which is essential to the correct understanding of disorders of the digestive tract. The student is not harassed with numerous theories as regards the processes of digestion, but the facts are stated simply and comprehensively. The causes of indigestion are then considered, special stress being naturally laid on the alterations in the quality or quantity of the gastric juice. The symptoms of dyspepsia are

notably numerous and uncertain, but the author of this work has not shirked his task, and has chronicled them in a most satisfactory manner. He draws attention to some that are but little recognised or rarely referred to their true cause, such as a "feeling of constriction at the root of the nose," which Dr. Herschell states is a very distressing and not uncommon sensation, and adds that it is relieved at once by the insufflation of a little menthol or cocaine. The objective examination of the digestive organs is fully detailed, and then the clinical varieties of indigestion, with special reference to diagnosis, are discussed, the chief points which are considered being the main differences between chronic catarrh of the stomach and functional gastric indigestion—"atonic dyspepsia." The chapter on treatment is naturally the one to which readers will turn with most interest. It will well repay close perusal and study. Diet holds the first place and exact directions are given for the management of the meals in the different varieties of dyspepsia which are met with. Here we should like to offer one suggestion, and that is that the few excellent French formulæ should in the next edition be given in their English equivalents. We congratulate the author on his work, and recommend it to all who wish to successfully combat that most troublesome complaint—indigestion.

*The Pathological Histology of Bronchial Affections, Pneumonia and Fibroid Pneumonia.* By A. G. AULD, M.D. London: J. & A. Churchill. 1892.

THIS work is manifestly the outcome of much patient research and thoughtful reflection. It embodies several newly noted facts in the normal and morbid histology of the air passages and lungs, and is outspoken in criticism of current teaching on certain points. Indeed, it is not often that the study of the structure of the bronchi is so fully treated. The author shows that the earliest stage of bronchial inflammation involves no change in the epithelial elements, but is purely a condition of vascular engorgement and subepithelial exudation. Then comes swelling of the surface cells, an increased outpouring of mucus, and at the end of twenty-four hours the characteristic process of proliferation and degeneration of the epithelium. Although he admits the difficulty in the way of obtaining proof that there is also actual diapedesis of cells from the vascular territory to the surface, he is not inclined to agree with Hamilton that this does not occur, and indeed he describes the transit of leucocytes through the basement membrane. In addition to these phenomena there are of course changes in the mucous glands, which are succinctly described. In the later stages Dr. Auld finds evidence of proliferation of the connective tissue cells, and he boldly traverses Cohnheim's views of the origin of pus. In respect to the pathology of chronic bronchitis he prefers to attribute the hyperplastic changes which are to be observed in the epithelial as well as in the fibrous elements to an atypical growth rather than to simple inflammatory processes; and he has found that this overgrowth also concerns the muscular and even the cartilaginous structures. Subsequently in this disease atrophic and degenerative changes set in. The section on Bronchiectasis contains also several points of original observation, such as the detection of "aberrant" smooth muscle fibres in the wall of bronchiectatic cavities, and the transformation of the epithelial lining of the bronchi into a layer of flattened cells and duct-like processes which can be seen in the inner walls of the sacculations. The duct-like formations are, he thinks, derived from the acinous glands. He inclines to the view that the chief causes of bronchial dilatation are collapse and atrophy of the pulmonary tissue. There is a chapter on Bronchial Asthma in which the congestive theory is disputed; but the most interesting portions of the book are those which

deal with broncho-pneumonia, acute pneumonia and fibroid pneumonia. On the last-named subject Dr. Auld has much to say that is of value, and his conclusions are, in the main, justified by the observed facts. Altogether the monograph is a creditable piece of work.

#### OUR LIBRARY TABLE.

*Plutarch's Life of Themistocles.* With Introduction, Critical and Explanatory Notes, Indices and Map. By HUBERT ASHTON HOLDEN, LL.D. Third Edition, rewritten and enlarged. London: Macmillan and Co. 1892.—Those of our readers who wish to retain or revive a working knowledge of Greek could not do better than make this compact little volume the companion of their holiday. Its publication as a first edition some years ago anticipated, and indeed promoted, the present reaction in Plutarch's favour in our schools and colleges, and it has been followed up by others of the same delightful author's Lives—those of the Gracchi, for instance, of Sulla, of Nicias and of Timoleon—all edited by the same highly accomplished scholar and teacher—brother, we may incidentally remark, of Mr. Luther Holden, the veteran anatomist and demonstrator. Every help will be found by the intelligent reader to have been judiciously provided for him, just so much having been left to his independent judgment as to keep it in wholesome exercise during the process of translation. Besides the charm inseparable from Plutarch's work, the Greek in which he writes is of special value for the light it throws on the language of the New Testament.

*The Life of Francis Duncan, C.B., R.A., M.P., late Director of the Ambulance Department of the Order of St. John of Jerusalem in England.* By HENRY BIRDWOOD BLOGG, M.A., Vicar of Frodsham, Cheshire; with an Introduction by the Lord Bishop of Chester. London: Kegan Paul, Trench, Trübner and Co., Limited. 1892.—This is a memoir of the late Colonel Duncan, R.A., who was well known in connexion with ambulance work in this country and Egypt. Colonel Duncan spoke in the House of Commons on one occasion in favour of the medical department of the army, urging that its officers had to serve too long abroad and recommending that they should be allowed leave every six or seven years for the purpose of study; also that field hospital work should receive more attention in their ordinary training. Colonel Duncan was an energetic, enthusiastic, and most excellent man and this little memoir of him is an interesting one.

*Illustrated Lectures on Nursing and Hygiene.* By R. LAWTON ROBERTS, M.D. Lond., D.P.H. Camb., M.R.C.S. Eng., Associate of the College of State Medicine &c. Second Edition. London: H. K. Lewis. 1892.—The general scope of the second edition of this work remains unaltered, but additional information is given on the artificial lighting of rooms, the dietary of the sick and other matters. Its contents are mainly arranged on the plan of the syllabus of the advanced nursing course of the St. John Ambulance Association, and call for little in the way of description or comment. It is a very useful book and enters more fully into details than most works of the kind with which we are acquainted. The lectures on the sick room, food and drink, contagious or infectious fevers and on observation of the sick are good. The information supplied is clearly if rather diffusely given, and the directions are plain and sensible, and, with the aid of the illustrations, easily comprehended. The book has a fairly copious index, which adds much to its usefulness and to facility of reference.

*Lip Reading.* By WILLIAM VAN PRAAGH. London.—In this little pamphlet the author conveys some useful hints for instruction in lip reading, and speaks with authority on a subject which he has long taught and expounded. The instinct which leads those deprived of hearing to utilise the

other senses, especially sight and touch, to gain information more easily conveyed by sound, is the foundation of the subject. It is, in short, a refinement and development of gesture speech; and the proficiency attainable by scholars is dependent largely on the state of their general intelligence, which rules the acquisition of articulate speech as a whole. Sometimes cases are observed in which vocal expression, resulting from lip reading, is painfully defective and is often peculiar. There is in many cases an almost distinctive tone and manner of speech; but the fact, which we have ourselves observed, that the deaf mute may acquire a provincial accent shows to what a degree of perfection an intelligent pupil may attain in lip reading. Not merely deaf mutes, however, but adults who have from any cause become incurably deaf may be restored to communion with their fellows by this means.

*The Journal of Physiology.* Edited by M. FOSTER, F.R.S. Vol. XIII., Nos. 3 and 4. Cambridge: Cambridge Engraving Company. 1892.—The following are the contributions to the present number of this journal:—1. A Contribution to our Knowledge of Taste Sensations, by L. E. Shore. 2. On the Respiratory Changes of the Intra-thoracic Pressure measured in the Mediastinum Posterior, by S. J. Meltzer (with two plates). 3. On Retractable Cilia in the Intestine of *Lumbricus Terrestris*, by M. Greenwood (with a plate). 4. On a Large-fibred Sensory Supply of the Thoracic and Abdominal Viscera, by F. H. Edgeworth (with a plate). 5. On the Nature of Cobra Poison, by A. A. Kanthack. 6. Further Observations on the Influence of Calcium Salts in promoting Heat-coagulation of the Albumins, by Sydney Ringer. 7. The Protective Functions of the Skin of Certain Animals, by W. B. Hardy. 8. On the Excretion of Uric Acid and its Estimation by Hayercraft's Process, by A. Haig. 9. On the Fibres of Retiform Tissue, by R. A. Young.

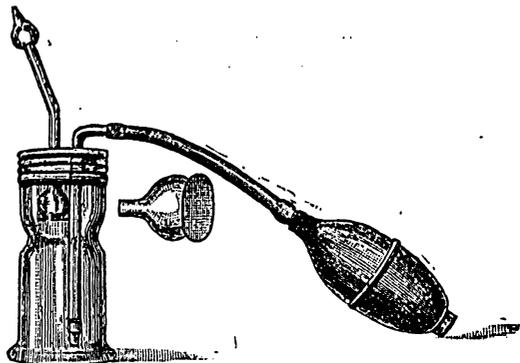

*Guide to the Administration of Anæsthetics.* By HENRY DAVIS, M.R.C.S. Second Edition. London: H. K. Lewis. 1892.—The present edition contains some additional matter, but in the main is a reprint of the first. The relative safety of anæsthetics receives special attention. The practical details of his subject occupy Mr. Davis's attention rather than the more recondite questions of physiology, and he has endeavoured in his book to present his facts, descriptions and directions clearly and succinctly.

## New Inventions.

### THE "PULVERFLATOR."

THIS is an apparatus designed to facilitate the efficient use of the compound zinc stearate combinations in the treatment of the naso-pharynx. It consists of a glass reservoir for a powder, closed by a rubber-fitted screw-cap, carrying two glass tubes—namely, a valved blowing-tube with a rubber bulb attached and a distributor. The latter is a glass tube with a conical end adapted for applying to the nostril; this may be replaced by other tubes designed for the larynx or urethra. The cloud of powder raised by the air current forced in by the rubber bulb is screened through a small glass funnel, over which a piece of fine "bolting" cloth is attached. In this way the discharge of the powder in an extremely fine cloud is effected; in fact, when projected into the air, it very closely resembles ordinary smoke. When an antiseptic, a stimulant, a drying or other medicament is mixed with the compound stearate and applied to the diseased area the latter is not only covered and protected by the powder, but, owing to the adhesiveness and persistence of the stearate, it is subjected to prolonged therapeutical action. From its specific lightness, its power of clinging to the membrane and its impenetrability by aqueous liquids the compound stearate is claimed to be

specially useful for the medication of the mucous membrane of the nose and throat. We have examined a specimen of pure stearate of zinc and find that it exhibits no tendency to become rancid or to decompose. It is therefore eminently adapted as a vehicle in the treatment of skin affections, or in morbid conditions of the mucous membrane of the nose and throat. Compound zinc stearate is prepared containing also various active therapeutical agents, such as boric, sali-

cylic and tannic acids, bismuth subgallate, cocaine, exalgine, ichthyol, menthol, tar, salol, resorcin, sulphur &c. Messrs. McKesson and Robbins of New York have recently introduced the "pulverflator" and have given special attention to the preparation of the compounds for the administration of which it is designed. The zinc compounds, together with the apparatus, may be obtained of the London agents, Messrs. Maw, Son and Thompson.

### TIN-LINED IRON PIPES FOR THE CONVEYANCE OF WATER.

WE have received the following communication from Messrs. Walker and Co., of Heckmondwike, Yorkshire:—"Our attention has been directed to your remarks in *THE LANCET* of July 23rd on tin as a metal for conducting water, and we note—though you admitted the suitability of this metal for such purpose—you go on to state 'that, if it did not possess certain other disadvantageous properties which preclude its practical employment, no better material could be found.' This fact we have proved to our full satisfaction by long and careful experiments some time since, and we have therefore set to work to try to overcome the very objections you mention, and we now venture to assert that in the tin-lined iron we have succeeded. We are sending a small sample, from which you will see we have the full benefit of a pure tin pipe at the least possible cost, yet combined with the greatest strength. All the fittings—such as T-pieces, elbows, bends &c.—are lined through and all tested to over 2000 lb. to the square inch before leaving the works. No soldering being required, it is both cheaper and easier to fit than lead and gives great satisfaction." In the article referred to, whilst it was admitted that no better metal than tin could be employed, especially as regards its power of resisting the solvent action of water, the drawbacks to its use—namely, its hardness, its inflexibility and its expense—were also pointed out. The "tin-lined iron pipe" overcomes one difficulty, that is in respect of expense. At the same time the invention is a valuable and an ingenious one. Such a pipe is for all practical purposes equal to the pure block-tin pipe; and, if it were adopted, no more would be heard of the contamination of drinking water with poisonous metal. Of course, if it can be shown that no other remedy is forthcoming, then lead-piping must be abolished and an innocuous substitute be used. Tin-lined iron-piping might be employed with advantage, we suggest, in certain manufacturing operations, as, for example, in distilling processes and in the preparation of aerated beverages.

# THE LANCET.

LONDON: SATURDAY, AUGUST 6, 1892.

"BOIL your ice." Such is the counsel given by Dr. DAREMBERG to the Parisians in view of impending cholera, and the lesson which underlies the somewhat quaint saying contains the pith of the advice which is necessary for the prevention of cholera. It is now many years since we found that freezing does not destroy the ordinary contagia of the diseases of man. We learnt from Massachusetts of the first epidemic of enteric fever, which was traced to the use of ice from a sewage-polluted pond; and only the other day Dr. GEORGE TURNER presented to the London County Council a most interesting report on the prevalence of enteric fever in the East-end of London through the consumption of "ice-creams," bought from itinerant Italian vendors, whose ingredients were stored under conditions that leave but little doubt as to where the infection came from. "Boil your ice," being enlarged in the scope of its application, becomes for us "cleanliness in all things"—in food, in drink, in all our surroundings. This is the true means of cholera prevention.

In one form or another we have promulgated this doctrine again and again for the last two months; and it is because we attach such enormous importance to it that we avail ourselves of Dr. DAREMBERG's pithy saying to recur to it once more. The lesson has been taught in every official memorandum issued by the Local Government Board; it was to secure cleanliness in advance of all danger of cholera that in 1883-85 the Government "Cholera Survey" was instituted; and the avoidance of filth in old garments and bedding was the object that recently led to a prohibition on the importation of "rags" into this country from France and from the ports in the Black Sea and the Sea of Azov. Sir ROBERT RAWLINSON, eminent in engineering, but naturally not so skilled in preventive medicine, writes to the public press and says he is "ashamed" that our Government should take such a step as this in its aim after cleanliness. Privy Councillor Dr. HIRSCH, on the other hand, with a world-renowned fame as a student of epidemiology, and with ability to appreciate to the full the immense value of public sanitary works, sends word from Berlin to this effect:—"The importation of rags constitutes a most serious danger and should be prohibited from any infected and even suspected district." On the same day comes an account of four fatal cases of cholera at Gonesse, owing to the fact that a disobedient attendant had taken the clothes of a cholera patient to his own house instead of burning them. Anyhow, we prefer the advice to maintain cleanliness in all things and in no way to limit the application of the doctrine to mere constructive matters such as deal with water-supply and drainage.

We have already given our reason for recurring to this subject, and wish to avoid all appearance of panic-making. There does not appear at present to be more danger to this country than we should at all times be prepared to face. In this connexion we may again refer to

Dr. HIRSCH. He tells the inhabitants of the German capital that he has but "little fear as regards Berlin." And his ground for this is that the sanitary system of the city has within modern times become so much "perfected" that, whilst isolated cases and importations may occur, he sees no danger of an epidemic. Here, again, it is on the advance towards cleanliness, of air breathed, of water consumed and of the soil on which Berlin is built, together with the security taken against the importation of filthy articles, such as rags &c. from infected areas, that Dr. HIRSCH relies. To some of us the message may seem a little over-confident—indeed, it may have been transmitted without some of the cautions with which it should have been accompanied. Indeed, in calling the attention of our sanitary authorities and fellow countrymen to the lesson it conveys we would approach the subject from another point of view. We rather are credited amongst the nations of the world for having made greater strides towards cleanliness, both public and private, than any other country. But those who have taken part in this invaluable work and progress are, of all others, best aware of the large arrears that have yet to be made up and of the ample room that remains for further progress. There are spots in abundance that seem almost to be waiting their opportunity to impress more emphatically the lesson that epidemic cholera and filth go hand in hand. There is the barbarous and revolting middenstead system of our northern counties, polluting air and soil by its emanations and soakage; there are similar systems in the south and elsewhere under which it has become a custom to dig two holes in every man's garden and then to pour all liquid filth into one which is called a cesspool, whilst the drinking water is drawn from the other one which goes by the name of a well. There are houses by the thousand in which the drinking water is drawn from a cistern which also serves a water-closet, and which is also placed in direct communication with the house-drain by means of its overflow pipe; and there are houses in every town by the score and even by the hundred in which there is no such proper disconnection of house-drain and waste-pipes from the public sewer as to free them from risk of the ingress of that sewer air from public culverts, which may at any moment be a means of conveying the contagium of imported cholera. Our communities are the more to blame because they can no longer plead ignorance. There are members of sanitary authorities who will not provide proper means of sewerage and of water-supply because they fear to lose their seats on the boards at which they sit; there are communities who deliberately elect opponents of sanitary reform because they prefer a risk which seems somewhat remote to a certainty of increased rates; there are public bodies who leave individual inhabitants to perform works of cleanliness and scavenging which they are aware they cannot properly carry out; and there are householders who live on year after year in dwellings into which they know sewer air can make its way by one channel or another—indeed, such people can be everywhere found in abundance. It is communities and persons such as these who will be among the first sufferers if cholera should come, and it is the towns and localities in which they live which will constitute a standing danger to the community at large. On the other hand, if they will but amend their ways, they will be the first to benefit, for, whether cholera should come or not, we have ample experience to show that

permanent measures adopted against that disease have contributed more than anything towards a diminution of those infectious diseases—and notably of enteric fever—which we have always with us, and which are so costly a burden owing to the sickness and death by which we are deprived of the lives and labour of the breadwinners, who constitute the most remunerative element of the State.

THE selection of such a subject as bacteriology for one of the three general addresses delivered at Nottingham before the British Medical Association is a sign of the times. It clearly demonstrates how firm a position has already been gained in medical thought by one of the collateral sciences, besides testifying to the importance of the place which it occupies among them. It is little more than a decade since this subject gained any prominence, and the remarkable researches of which it has been the source have flowed in such abundance as to overwhelm the slower progress of other branches. The subject is so fascinating and the way is so open to new investigations that its rapid advance is hardly matter of surprise; and although in more than one direction the path has seemed closed, and steps have to be retraced, yet on the whole the amount of actual progress within the memory almost of the youngest follower of medicine has been surprisingly great. The opportunity for taking stock of the knowledge already possessed and for indicating the lines upon which research has still to be pursued in this subject has been wisely seized; whilst the exposition of the matter could not have been entrusted to a bacteriologist better qualified for the task than Dr. SIMS WOODHEAD, whose address will be found in another column. He was justified surely in pointing with something like pride to the recognition that bacteriology has obtained; and his survey must have impressed his hearers with the fact that the confidence placed in bacteriology is fully justified. This it could never have received had the study of bacterial life been merely that of the botanist. It is on account of its intimate relationship with the vital processes, normal and deranged, of higher organisms, because of the light it sheds on parasitic action and the intimate processes of cell nutrition, that it has laid hold of the scientific imagination and revolutionised pathological ideas.

It is not surprising that bacteriology should have paved the way to many theories concerning the method of action of bacteria upon the organism in which they flourish. As Dr. WOODHEAD reminds us, the earliest notions were based on the effects produced by mere mechanical arrest of the circulation through accumulation of the microbes in the bloodvessels; but when this view was found to be insufficient theories were propounded as to the parasites requiring for their maintenance the oxygen which the cells of the infected organism could not lose without being devitalised. Still this view lacked general confirmation, and hence it has come to pass that the chief rôle of bacteria in respect to disease is now considered to be played in connexion not with deoxidation but with the formation through their action of chemical substances inimical to cell nutrition. The various morbid processes with which we are familiar in the facts of pathological anatomy, have thus

many of them an origin in parasitic organisms. Inflammation, as Dr. WOODHEAD pointed out, has been largely explained in this way; and it is by no means improbable that some at least of the forms of neoplasms may be initiated through such agencies. It is, however, in the class of infective diseases that the influence of micro-organisms has been most clearly shown, thus bearing out the truth so long only guessed at that there are germs of disease, although the meaning to be attached to such a phrase is materially different from that assigned it by the earlier theorists. Dr. WOODHEAD selected diphtheria as an example of the affections in which the mode of action of the infective microbes has been most fully studied. He reminded his hearers that the early experiments of Professor LOEFFLER, who separated the bacilli from their products by filtration, and the subsequent observations of Professors ROUX and YERSIN yielded results in complete harmony with the interpretation of the clinical phenomena of the disease, in which the profound general disorder of tissues and organs ensues upon the primary local manifestations. These observers established the fact that the diphtheritic organisms are not to be found in the body beyond the site of inoculation, and that the general effects were produced by their products. Dr. SIDNEY MARTIN succeeded in isolating the poisons thus produced. He showed that the essential chemical agencies which exert so powerful an influence on the tissues in diphtheria were albumoses, and it is remarkable that he also failed to detect any alkaloid as in anthrax, but a feeble organic acid which had a poisonous effect on the tissues similar to, but far weaker than, that of the albumoses. The mode of formation of these substances from the fibrinous exudation that forms on the unhealthy mucous membrane which serves as the point of attack of the diphtheria bacillus has been admirably worked out by Dr. MARTIN, and was clearly summarised by Dr. WOODHEAD. In this chain of processes, commencing with the specific bacillus, its appropriate media, its power of producing a ferment or enzyme, and the further effect of this in the conversion of fibrine into albumose, we find the most complete presentation of the mode of action of pathogenic bacteria which can be desired; and the field, previously explored by Dr. MARTIN as regards anthrax, is open for multifold inquiries on the same lines throughout the whole range of infective disease. It is indeed true that in chemistry lies the solution of many a pathological problem, as was clearly foreseen by the late Sir W. AITKEN, to whom appropriate reference was made by the lecturer. Incidentally Dr. WOODHEAD suggested some improvements in the way of making greater use of opportunities for the application of bacteriological knowledge to immediate practical purposes, being led thereto by the advocacy of Professors ROUX and YERSIN of culture observation in the diagnosis of diphtheria. We commend his suggestions to the notice of the profession.

Yet so far in his address Dr. WOODHEAD had not touched upon the matter which was doubtless uppermost in the minds of many of the medical practitioners who were listening to his exposition. He had sketched, with a clearness which all could appreciate, the steps whereby we have attained to our present conception of pathogenic organisms and their action. May not some have asked themselves whether this increase of knowledge of the nature and action of bacteria had any light to throw

upon the means of counteracting their effects, whether insight into treatment was to follow on insight into pathology. Dr. WOODHEAD did not leave them long in doubt, but presented as clear a statement of the question of protective inoculations. That "anti-toxines" do exist in some of these infective diseases, if not in all, must be admitted from the evidence; but that they act in any other way than as stimulating and reinforcing protoplasmic reaction to bacterial poisons is improbable. Again, in some diseases the protective influence of previous attacks or of repeated non-fatal inoculations may be ascribed as the "acclimatization theory"—that the cells of the body gain in their powers of resistance under the action of the poisons themselves. He showed, too, how different this action was from that which occurs in the tuberculin treatment, where necrotic changes are set up by the agent acting in conjunction with the bacillary poison itself, and he did not hold out much hope of such a process having a permanent effect. Lastly, preventive treatment by inoculation with attenuated virus was dealt with and due credit given to our own countryman, Professor GREENFIELD, whose labours on anthrax have been overshadowed by the work of M. PASTEUR and his school. We believe that there is a great future in store for bacteriology, and it is likely enough that many views now held on the subject will in course of time receive much modification. Still it is impossible to be unaware of the very striking and, in the main, harmonious results that are being gleaned from all the laboratories in the study of the subject; and it is gratifying to our national pride to know that, in spite of many and great difficulties, some of the most notable advances have been made by workers in British laboratories.

It was foreseen that the Notification of Infectious Diseases Act would in various ways raise difficult and delicate questions between the medical man and his patient, the medical man and the public, and even between one medical man and another. In the actual working of the Act these views have been realised. Those who keenly opposed this Act may see in its results a confirmation of their objections, and may still wish that it had never been passed. A closer view, however, of the subject will show that such wishes are futile. It is clear that the public is bent on reducing to a minimum those diseases with which the Act deals. Even a change of Government is not likely to alter the determination to make it compulsory instead of, as at present, optional. There are various reasons for this. Mere economy is one. The cost of the cure of infectious diseases is being more and more thrown on the public. The fever hospitals are being used by an increasing number of persons and by classes of a higher social position than formerly. If the State sees its advantage in receiving such patients into isolation hospitals, it will also see to the best means of limiting the number of cases to be admitted. Society is determined on restricting individual liberty. It will not, if it can help it, allow the individual to contract infectious disease, or, having contracted it, to freely diffuse it. This may be a great inconvenience to the individual, but it is clearly right. Under these circumstances we have to consider, as medical men, our own duty in respect to the Act, which may be strengthened but will not be repealed.

Our first duty, in the light of the requirements of the Act, is to perfect our skill in diagnosis. Legislation has emphasised the importance of this art and any mistake therein is calculated to bring our defects into special prominence. There are some cases in which diagnosis is not urgent. We may take time to make up our minds. There are other cases in which promptitude of diagnosis is a virtue, provided that it be sound. We must not be understood to recommend any undue haste. Diagnosis cannot in any case be hurried. Time must be given for the development of the symptoms on which it must be based. Typhoid fever is especially a case in point. By exclusion of other diseases the practitioner may have a shrewd suspicion that his patient, with the persistency of a certain pyrexia, is suffering from this disease; but it would scarcely be judicious to consign him to an isolation hospital before the appearance of rose spots or of characteristic diarrhoea. Still there may be undue delay in forming a diagnosis till cases have multiplied and avoidable mischief has been done. Mistakes in diagnosis are inevitable, especially in regard to infectious diseases. The managers of the fever hospitals say that they are even on the increase. Four hundred and eighty-eight patients were sent to these hospitals in the course of 1891 who were found not to be suffering from the diseases mentioned in the certificates on which they had been received. The percentage of errors in the diagnosis of patients sent to these hospitals is alleged to have increased during the past five years from 2.4 to 6.2. This, if correct, is a most unsatisfactory result, but it is not altogether unintelligible. The duty of notification has been thrown on the profession somewhat suddenly and failure in the discharge of the provisions of the Act has been severely punished. In some respects the opportunities afforded to students of seeing the infectious class of diseases have been reduced, first by the abolition of pupillage, and secondly, by the increasing tendency to exclude such diseases from general hospitals. When the intrinsic difficulty of diagnosis is considered—a difficulty experienced by experts, who make their share of mistakes—the wonder, indeed, is that only a few errors are made in dealing with so many thousands of cases, many of which occur under circumstances very unfavourable for a careful observation. Still we must not regard those mistakes lightly, and they should be reduced to a minimum. One of the medical officers of the Metropolitan Asylums Board, Dr. BIRDWOOD, medical superintendent of the small-pox ships, has, with this view, suggested that in small-pox cases—and we presume he would apply the rule to other diseases—the ambulance conveying the patient should be accompanied by a medical man, having experience of the disease, to confirm the diagnosis. The suggestion is in some respects of a rather impracticable nature, although to many it may seem no excess of precaution to require that before consigning a person to the risks of an infectious hospital two medical men—as in the case of insanity—should certify to the nature of his disease. But even if such a regulation should be made, it is alike the duty and the interest of every practitioner to be acquainted with the essential symptoms of the notifiable diseases. Such an acquaintance can only be obtained by careful and minute clinical study. There is but little excuse now for medical students who do not make this acquaintance. The hospitals of the Asylums Board have

been opened to them through the efforts of the College of Physicians and the action of the General Medical Council. Medical men in actual practice can by taking due pains eliminate all but a few doubtful cases. Deliberation must be practised in taking the history of the case and ascertaining the chances of exposure to infection, though this often cannot be traced. The clinical thermometer must be used invariably. He would be a rash practitioner who would fail to use it before notifying, or would send a patient into a hospital for infectious diseases with a temperature under 100° F. To an observant practitioner nothing will be lost. The symptoms at the onset will be well studied as well as those of the fully developed disease, and his carefulness will in this way be matured. There is no royal way to infallible diagnosis. It is only by multiplying good reasons for a diagnosis that it can be sustained or justified, and these good reasons can only be obtained by observation and by reflection on the possibilities of error.

There remain the doubtful cases. What is the practitioner's duty in regard to these? Every day increases his responsibility. He cannot notify till he is satisfied that the patient is suffering from a notifiable disease; but he is by no means free from risk of blame if such a disease is before him and he fails to see it when he should be aware of its presence. To prevent such an error, and the perhaps greater one of notifying that which does not exist, the most reasonable course is in doubtful cases to seek the advice of another practitioner. This is one of the cases for the opinion of an expert. If a patient cannot pay a fee for such a consultation, an experienced friend is generally available, with whom counsel should be taken. When reasonable doubt still remains, or if the consultant or the experienced friend hesitates to pronounce the presence of notifiable disease, it is obviously right to give the patient the benefit of the doubt. But in all such cases the possibility of a spread of infection should be carefully guarded against by as complete an isolation of the patient and disinfection as is feasible. The great point of ethics in this matter is to cultivate accuracy of judgment, and in doubtful circumstances to do to others as we should wish them to do to us. The mere fear of being detected in an error of diagnosis is not a high consideration, but together with others of a higher nature it should prompt us to vigilance and care in the discharge of one of the most important of our functions.

It may be not inopportune, at a time when the distribution of the great annual collection made by the religious bodies of the metropolis on behalf of our accredited medical charities is announced, to call attention to a great evil, none the less serious because pertaining to that large class of wrongs which are "wrought by want of thought" rather than by "want of heart." The evil to which we allude is that of the promiscuous lending of names—done in all goodfaith and with the best intentions, but so hastily and so unreflectingly as to be productive of incalculable harm. For our present purpose it will suffice if we select two examples of the mischief resulting from this practice, and ample evidence of its existence can be found any morning in the advertisement columns of our contemporaries. A would-be benefactor, for some reason or other—we put it pur-

posely as indefinitely as possible—proposes to add one more to the already excessive number of London medical charities. For this purpose the first thing to be done is to secure the names of a number of influential and well-known people to figure on the list of patrons, vice-presidents, council and the like. The facility with which this object can be attained is astonishing. Holders of the proudest titles—persons of all others, it might be thought, who would be most jealous of the dignity of their names—out of pure good nature, and for the mere asking, sanction their use by the first applicant who comes pleading the cause of what is apparently charity. The "Hospital for Diseases of the Great Toe" (to take a humorous illustration once suggested by Sir ANDREW CLARK) is no sooner started than it commands the patronage of half the aristocracy and a respectful following of City magnates and plutocrats. It is perhaps doubtful whether any one of these gentlemen directly contributes a single penny towards its endowment or support, but the lending of a name costs nothing, and no active measures are required, save perhaps the pleasant labours involved, especially on the part of the ladies, in the holding of a fancy dress bazaar or a private theatrical entertainment. People who lend their names in this unthinking fashion never pause to consider whether the object in view, however meritorious at the first blush, is either necessary or desirable. In the case cited if these nominal patrons were to consult their medical advisers they would probably at once learn that, owing to the want of funds, many of the general hospitals in London have beds unoccupied, and even closed wards, whilst the money their names will attract into the coffers of the "Hospital for Diseases of the Great Toe"—for

"Some to the fascination of a name  
Surrender judgment hoodwinked"—

would have placed these beds and wards at the disposal of many applicants who now, alas, have to be turned away. Moreover, they would be told that the multiplication of special hospitals is viewed with disfavour by the profession as a body, and is quite unnecessary, seeing that the general hospitals are provided with special departments. We have no hesitation in saying that, speaking broadly (for there is no rule without exceptions), the rivulets of the stream of charity—and even the smallest of these, properly directed, may prove of eminent service to suffering humanity—if diverted from the legitimate channels of the general hospitals and allowed to irrigate the comparatively unnecessary pastures of highly specialised institutions not only run to waste, but serve to obliterate the landmarks which indicate the more useful and, in our opinion, more deserving harbours of refuge always open to sufferers, be they the victims of a general constitutional disease or of a purely local trouble affecting, let us say, the distal phalanx of the great toe!

The other example of the injudicious "lending of names" which we had in mind is of a different nature, and one in which those who err are of a less distinguished class of society. We refer to the published testimonials of the efficacy of quack remedies, cure-all nostrums *et id genus omne*. The reader of this remarkable species of literature is naturally inclined to believe that such testimonials are not genuine, and to regard them as merely the ingenious outcome of the fertile brains of enterprising and irresponsible advertisers. It has been proved, even

we fancy, in courts of law, that many of them are; in fact, instances either of misplaced gratitude of an evanescent nature or of fortuitous circumstances. Still, this does not by any means increase their value. The subject has undoubtedly a certain psychological interest; for what bent of mind must those persons have who, by iteration and reiteration, are convinced that the claims of quack medicine vendors, outside stockbrokers and turf prophets are worthy of credence? The cynical remark of CARLYLE that there are so many millions of people in the world—mostly fools—would, we fear, appear to be not less applicable now than in his days, for of a certainty the cost of these advertisements is eventually paid out of the pockets of the British public and not out of the purses of their shrewd authors.

In conclusion we would appeal to members of our profession to acquaint their patients and their friends, as they may have opportunity, with the real worth of the claims of those magnificent institutions, our great general hospitals; and to impress on them the folly—nay, rather, the positive harm—of lending their names “because they are asked” and, we may add, because they are too good-natured and sometimes too indolent to refuse.

---

### Annotations.

“Ne quid nimis.”

#### THE METROPOLITAN HOSPITAL SUNDAY FUND DISTRIBUTION.

IN the course of a very brief report the Committee of Distribution appointed by the Council of this Fund have dealt with the claims of a hundred and seventy-six institutions and the awarding of £40,118. It appears that the investigation made by the committee has resulted in adverse criticism in sixteen cases, one of which proved upon examination by the light of explanations afforded by its committee to be open to no reproach and has accordingly received an award upon the full merit basis. The remaining fifteen have been less able to meet the criticisms of the committee. Seven of them appear to have acquiesced in the strictures passed upon them, five others have tendered explanations but without fully convincing the Distribution Committee of their freedom from blame, and three have been altogether refused any participation in the Fund. It is well that these facts should be generally understood, for it is plain that the effect of such criticism must be most salutary, and the public will place confidence in the administration of the Fund when they perceive that the supervision exercised by the Council through the Distribution Committee is very far from being a dead letter. Another point of equal importance is that to which, in moving the adoption of the report, Sir Sydney Waterlow called attention—namely, that the awards are made not simply upon the basis of the work done by the various hospitals, but also and even more directly in proportion to their needs. Of two institutions doing practically the same amount of work one may stand greatly in need of help and the other in little or no need at all. It is most proper that this aspect of the case should receive the consideration of the Distribution Committee, and we should have supposed that it was generally understood that this is, and must be, the fact, if it had not been that the House of Lords' Committee manifests some imperfect appreciation of its being so. We have repeatedly stated this in the pages of THE LANCET, and have again and again explained the

manner in which the committee proceeds; but there is still occasion to repeat the statement, since some, at least, whom it most concerns to understand these matters appear still to be under some misconception respecting them. In connexion with the Hospital Sunday Fund we may be allowed to express our gratification at the honour conferred by Her Majesty on the Lord Mayor in appointing him Knight-Commander of the Most Distinguished Order of St. Michael and St. George. Sir David Evans has been most assiduous and courteous in all the functions of his high office, and has well sustained the character of the Mansion House, not only for hospitality, but for ready and sympathetic help to the needy in their distress. When honours are a reward for such services they benefit alike the State which gives and the citizen who receives them.

#### HEAT STROKE IN AMERICA.

THE phenomenal heat-wave which for upwards of a week visited the chief cities of the United States not only deranged traffic and business to a remarkable extent, but was the cause of much sickness and mortality. It was stated that July 28th was the hottest day that had been experienced in that city for twenty-one years, and the death-roll then was such as to exceed the highest mortality ever known in twenty-four hours. On the 29th a temperature of 107° in the shade was registered, the deaths numbered 223, including 111 children under the age of five. Although on the 30th there was a fall in temperature the death-rate still remained excessively high, and it is stated that the total mortality in New York for the week ending at noon on the 31st amounted to 1434. Similar reports came from Chicago, and the same intense heat, with all its attendant discomforts and dangers, was generally experienced in the districts east of the Mississippi. No doubt the effects were the more severe since associated with the excessive temperature there was an abnormal degree of moisture in the atmosphere. The effects of heat on the human organism are not only seen in the occurrence of heat apoplexy or sun-stroke where the attack is sudden, the patient becoming comatose and hyperpyrexial, but in less severe cases it produces great nervous prostration and even cardiac depression. It was noted in New York that the worst effects were observed in the more densely populated districts of the city, and it is to be observed that not only did the human population suffer, but there was also a great mortality among the horses from the same cause—on one day as many as 1 in 5 of the horses employed by the tramway lines succumbing to the heat. As part explanation of these dire results it must be remembered that the conditions of life and habits of these large cities are ill-adapted to defend the inhabitants against such an abnormal rise of temperature.

#### “IN AID OF SICK CHILDREN.”

ON Friday, July 22nd, there was held in the Edinburgh Music Hall an exhibition of wild flowers, gathered all over Scotland by children, to whom prizes were given for the most effectively arranged specimens. Sixteen hundred was the number of the juvenile competitors, and there were on view in the hall 1642 exhibits, of which no fewer than 881 were bouquets of wild flowers prepared by children; while there were, in addition, 185 bouquets arranged by seniors, to say nothing of 254 bouquets of grasses. The spectacle was admired by numerous relays of visitors of all ranks throughout the day, to whom it was matter of equal surprise and delight that the highways and byways, the mountain sides and the river valleys, the moors and the marshes, could be made to yield so rich an assortment of floral colour at once delicate and glowing, and that the artistic taste and neat-handedness that grouped the flowers in such a variety of graceful forms were

so widely diffused among the humblest of the population. Nature herself was on exhibition in her freshest and most attractive *pose*, not only in her infinite wealth of outline and hue as represented by the flowers, but in the versatile contrivance and design manifested in the original, unsophisticated art of her child-votaries. Alternating with the vast array of hand-bouquets—combining heather, thistles, bluebells, wild roses, honeysuckle and white heather—were baskets and wreaths of the same, only less attractive in colour and arrangement; while the assortment of dried foliage from common British trees gave to the exhibition a scientific value dear to the botanical visitor. The prizes awarded by the umpires (among whom the chief place was appropriately held by Mr. Lindsay, curator of the Royal Botanic Gardens, and Mr. Dunn of the Palace Gardens, Dalkeith) amounted to 200, and consisted of watches, books and other articles of use to the fortunate competitors. But the real prize, in which all had more or less a share, was the education of mind and eye and hand conveyed in the gathering, the selecting and the arranging of the flowers into groups which by their artistic grace redoubled the native attractiveness of the flowers themselves, as they undoubtedly refined and stimulated the sentiment, the taste and the manipulative address that were expended on the handiwork. And, having served this most valuable of educative functions, the articles comprised in the exhibition were finally put on sale and the proceeds, mostly of small sums for the bouquets and flower baskets, were devoted to the funds of the Sick Children's Hospital. The chairman of the exhibition, Mr. John Leng, M.P., announced that in seven years as much as £1321 had been contributed by such means to children's hospitals; and Sir William Muir, Principal of Edinburgh University, dwelt on the beautiful thought which sent the healthy children of Scotland over the hills and dales of the native flora to gather flowers in aid of their little brothers and sisters lying in hospital. Charity and education were thus made to go hand in hand, teaching the lesson that nature-worship and art and science are never so admirable as when linked with the sentiment of humanity. Among the most effective promoters of the exhibition was Mr. Charles Jenner, whose propagation of wild flower culture and domestic gardening among our urban and suburban populations has already done much to refine and sweeten their lives. A munificent contributor to the floral decoration of the exhibition and also to the funds in aid of which it was promoted, Mr. Jenner confirms and enhances the honour attaching to a name, well-known in days past as well as present for its association with the science and the art of medicine.

#### HOME FOR EPILEPTICS.

THERE was published in *The Times* recently an influential signed letter calling attention to what it is hoped may one day develop into something like the well-known epileptic colony in Germany. The need for a home or refuge of some kind to which epileptics could be sent has long been felt by those who have been brought much into contact with such patients. Every convalescent home is closed against them, they are frequently incapacitated by their unfortunate malady from occupying positions for which in other respects they are well fitted, and they cannot be regarded, except temporarily, as suitable for treatment in hospital, even in those institutions which more particularly deal with such cases. A charitable lady, impressed with the wonderful success of the German colony, is making a laudable effort to imitate it in this country. A large house and grounds, we understand, have been purchased close to New Godalming, and the house has been suitably furnished to accommodate fifty or sixty patients. The management has been entrusted to a committee, but, although the house is now ready the

committee do not consider it prudent to throw it open until at least £500 are in the bank ready to be applied to the maintenance of patients. An appeal is made to the public for this sum. We cannot too strongly recommend such an object to a charitable public, and we wish the promoters every success in their efforts to alleviate the miserable lot of some of the most unfortunate amongst us. The inmates of the home are to be all females, and one of the best features of the undertaking is that it will be, to a certain extent at least, self-supporting. The patients are to be provided with suitable employment and are to be encouraged to assist towards their own maintenance; so that on the one hand they may be benefited physically by the light work which they would have to do, and on the other retain that self-respect which the objects of charity too often lose. We cordially wish the scheme every success, and we trust that it may be the means of bringing hope and cheerfulness to many a miserable existence. Messrs. Coutts and Co., 59, Strand, will receive donations or subscriptions in aid of the institution, which is to be called "The Meath Home of Comfort for Epileptics."

#### THE SHELLEY CENTENARY.

THE anniversary of the hundredth year since Shelley's birth was solemnised on Thursday last at his native town, Horsham in Sussex, by the foundation of a "Shelley Library and Museum" as the most fitting memorial that could be raised in the poet's honour. The institution in question is destined to absorb the libraries already existing on the spot and "to be governed in such a manner as to secure the support of all sections of the community." In addition to general literature, every work bearing directly or remotely on Shelley will be included in the library, while the museum will offer a home for such personal relics of the poet as the committee may be able to acquire. As a man and as a poet Shelley had his failings and defects—the failings and defects of his special and in some respects unique qualities. He was too ecstatic to be always sound; too impulsive to be always wise. But he was a high-souled, self-sacrificing "paladin in the liberation of humanity," whose heart beat responsive to the yearnings of his brethren for "the ampler ether, the diviner air" of social and individual freedom, and whose services were ever at the command of any cause, desperate though it seemed, that strove to make "all men's good each man's rule." There is, we understand, a corresponding movement in Italy to commemorate the good work rendered by the poet during his brief stay on the Tuscan seaboard in 1821-2; and in the monument erected at Viareggio, to mark the spot where his dead body was washed ashore and recognised by his friend Byron, a tribute will be paid to his generous espousal of the Italian cause in those dark years that followed on the reactionary treaty of Vienna. Over and above the historic deeds that link his name with the peoples' emancipation, political, social and religious, of which the latter decades of the nineteenth century are witnessing the fruits, his writings reveal a philosophic spirit in harmony with the most momentous findings of science, a spirit which under happier auspices might have worked itself clear of the crudities and morbid developments that vitiated his teaching and retarded his mission. The Greek culture to which his moral and intellectual being took so kindly fed his mind and soul with influences that required only scientific sustenance to make their practical outcome and their literary expression sound and clear. How susceptible he was of profiting by such sustenance may be seen in the wonderful generalisation that struck the keynote of his philanthropic life:—

"Nothing in this world is single;  
All things by a law divine  
In one another's being mingle."

What is this but a dim, poetic forecast of the axiom that

the universe is indissolubly connected with its minutest parts—that “the simple germination of a lichen is, if we apprehend it rightly, linked directly with the grandest astronomical phenomena, nor could even an infusory animal-cule be annihilated without altering the equilibrium of the universe”? The congenial gifts that made him one of the profoundest Platonists of his time doubtless prepared him for the teaching of the “Philebus” that the world is one huge animal organism, “the manifestation of some transcendent life, with which each separate individual life is related as is the part to the whole.” It is the undeveloped potentialities of his rich and many-sided nature that make his career and his writings at once so interesting and so tragically pathetic, and that qualify the physician, even more than the votary of any other calling, to share with special sympathy in the memorial tribute intended to “perpetuate his name and inspiration in the locality of his birth.”

#### THE FLY PLAGUE OUT OF DOORS.

LAST week we had occasion to discuss briefly some of the contrivances usually employed to combat the annoyance caused by house flies. We also noticed the fact that out of doors during the present hot weather a similar pest has to be encountered in a pre-eminent degree. Road, pasture, wood and mountain-side swarm with insects which attack the unprotected face the live-long day. The traveller cannot rest, the fisher cast his line, or the sportsman set himself to shoot but this *Musca volitans*, half a dozen at a time, is on his eyes. How best can the plague be met? Perpetual movement is impossible, and no degree of facial mobility would secure immunity; the hands have other duties. By common consent the veil, in one or other form, has been accepted as the surest and most ready means of defence. A correspondent mentions a visor of this kind as a suggested remedy. We cannot remember having met with this invention, but there seems to be no reason why it should not satisfy the needful requirements. Supported on a light wirework and made large enough to cover both head and neck, it could hardly fail to prove efficient. Still more simple is the contrivance adopted by our soldiers in Egypt—namely, a circular veil attached to the rim of the helmet, and falling down over the chest and shoulders. Health and convenience alike would gain by such additions to the armoury of comfort. That the bites of flies, in one at least of its species, may be the source of more than mere inconvenience has been already shown in our columns; and we record this week another example of the fatal results sometimes attending the attacks of these noxious pests.

#### SEASONABLE SANITARY WARNINGS.

A NUMBER of cautions are just now being issued by medical officers of health. Dr. Sedgwick Saunders in the City of London urges that care be taken as to water-supplies and as to milk. Diarrhoea is steadily on the increase, and in infants this often means contamination of milk in the wretched places in which it is stored—such as pantries opening out near dustbins. In the Trent Valley, certain inhabitants of the Gainsborough rural district are, notwithstanding the protests of Mr. H. Wright, the local health officer, and of the Local Government Board, still obliged to drink from the polluted river. In Essex Dr. Thresh issues notices of warning to the Maldon rural authority. In their district Latchingdon, Purleigh, Tiptree, Tillingham, and other places are in considerable difficulty. At Purleigh people who are willing to pay for a bucketful of water cannot get it; and all the while 40,000 gallons a day of excellent spring water near by at Danbury are running to waste. At Latchingdon the water is described as being like pea soup and as stinking. The truth is that many of the parishes in question are on the London clay, which is some 300 to 400 feet thick, water being procurable only by

deep wells bored through it or by surface ponds. The latter are all failing. The springs at Danbury would supply a large number of hamlets if the water were impounded. This would necessitate some twenty miles of piping, but the boon conferred would be immense and the outlay doubtlessly, in the end remunerative. Dr. Thresh has often given sound advice which has been followed with the best results, and we trust that his counsel in this important matter of a pure water-supply for the Maldon villages will receive the favourable consideration which it so evidently calls for.

#### TREATMENT OF HABITUAL ABORTION.

ASSAFCETIDA has been recently recommended in cases of habitual abortion. Dr. Turazzo gives it in pills containing a grain and a half as soon as it becomes clear that a new pregnancy has commenced. At first only two pills are prescribed, but later on the number is gradually increased to ten daily. The treatment is continued until the labour is over, and then the daily dose is gradually diminished. By this method cases where as many as five successive abortions had occurred have been successfully treated, and where in one instance a miscarriage appeared to be imminent during the seventh month it was averted and the patient was delivered at full term.

#### THE ARROW POISON IN THE NEW HEBRIDES.

M. DANTEO has examined and experimented with the arrow poison used by the natives of the New Hebrides. He finds that it contains neither vegetable poison nor serpent virus, but consists of earth impregnated with vegetable matter taken from marshy places and containing Pasteur's *vibrio septique*, or bacillus of malignant œdema and also the bacillus of tetanus. If the arrows have been kept a long time or have been much exposed to the sun the *vibrio septique* may have been destroyed; the danger then is from tetanus. When the arrows have been freshly prepared and the *vibrio septique* is still active a wound from them causes death in a guinea-pig from septicæmia in from twelve to fifteen hours; tetanus, which takes longer than that period of time to develop, does not under these circumstances show itself. It is interesting to remark that the horse is unknown in these islands, consequently the theory of the equine origin of tetanus would seem to be negatived by these researches.

#### THE VALUE OF NOTIFICATION.

THE rural sanitary authority of the Newton Abbot Union have been urged by a deputation from the inhabitants of Torquay, Paignton, St. Marychurch, Ashburton, and Cockington to adopt the Infectious Diseases (Notification) Act. The matter was referred to their medical officer of health, Mr. Harvey, who advised against it. He may have excellent reasons for this advice. Thus, the authority may have no means of isolating cases of infectious diseases when they hear of them, or their sanitary staff may be insufficient to do the work which would become necessary as the result of the increased sources of information as to disease in their midst. But the reasons which have been published in the local press appear to be singularly defective. One is that a subordinate inspector of nuisances would be more useful than the knowledge which the Act would provide; another seems to be that “notification meant quarantine.” We assume this to imply that an extra inspector might prevent disease, whereas notification would only give information after its occurrence. There is of course some reason in this; but everyone who has knowledge of a rural district must be aware that there are a number of diseases which are terribly fatal, which no action of a sub-inspector of nuisances can prevent. At all events, Mr. Harvey, knowing what is the state of the sanitary administration of this rural district, declares that notification would hardly be effective, and that it would lead

to considerable expence. The latter plea, which tells also in the direction of there being many cases of disease to report, seems to have carried the day, for the motion to adopt the Act was rejected. Newton Abbot must apparently wait till the Act is made universally applicable.

#### FRENCH CHOLERA PRECAUTIONS.

THE Prefecture of Police for the Department of the Seine have at last issued precautions against choleraic diarrhœa. As regards the actual sick the advice is given under three headings:—1. As to restoring warmth to the patient. 2. As to combating diarrhœa. 3. As to staying the vomiting. Then follow a number of preventive measures dealing with the water supplies, cleanliness, &c., and with the isolation of the sick, the disinfection of ejecta and of infected localities. Simple medical prescriptions are given in detail, and there is a statement as to the whereabouts of ambulances and appliances for disinfection.

#### INHALATION OF OXYGEN.

DR. GONZALES ALVAREZ of Madrid, in a paper on "Oxygeno-therapeutics" (*La Independencia Médica*, June 23rd, 1892), states that he has found oxygen inhalations of peculiar value in many of the diseases of childhood. A tube from the washing bottle of the generating apparatus can be placed in close proximity to the child's mouth and nose so that respiration is carried on with air containing a large proportion of oxygen, and of course it does not matter whether the child is awake or asleep. This plan has been found very advantageous in congenital debility, in asphyxia of newborn infants, in early scrofula, and in anæmia arising from any cause. In phthisis in adults Dr. Alvarez appears to have had more success from oxygen inhalations than has fallen to the lot of physicians in this country who have tried them. He mentions, too, a grave case of malarial cachexia in which this treatment was remarkably successful, the extravasation of blood simulating purpura hemorrhagica with extensive ecchymoses, epistaxis and mæna all passing off. Oxygenated water has also proved useful in the author's hands in many forms of gastric and throat disorder both in children and adults. Most patients cannot take more than a quarter of a glass without experiencing some nausea, but one old lady who suffered from dyspepsia and anæmia took for a considerable period a whole syphonful of the water with every meal, with the best results.

#### "MEDICAL HERBALISTS."

THE "National Association of Medical Herbalists" held its annual conference recently in Liverpool, and the President delivered an address which is certainly instructive, inasmuch as it gave some indication of "what they were, what they aimed to be, and what they desired to be." They are "medical dissenters" and they are employed by vast numbers as their "family medical advisers." They wish, in most praiseworthy fashion, to protect the people against unlicensed quackery; but *il faut vivre*, and the President has therefore made grave researches into the burning question of the penal clauses of the Apothecaries Act, and he announced, as the result, his belief that they were safe so long as they practised "without the assumption of medical titles." It is truly delightful to hear that we are not on the eve of a general convulsion of the universe; the "medical herbalists" are not advised to petition for the repeal of the old Acts, but they hope to level up until they gain some sort of official recognition. Here the logic becomes a little mixed. They proudly claim to have "erected no exclusive barriers," but they clearly hope to do so some day. They ask for no "selfish monopoly," but they denounce "the quacks who practise under the assumed names of herbalists." They are

yet (until they get the official recognition they desire) anxious to confirm the "medical rights" of the people, meaning by this platform-sounding phrase that "whoever they, the people, should call in to attend them should have a legal right to do so, irrespective of school, professional caste, or therapeutic belief." "Medical herbalists" are so often heard of at inquests and in other official inquiries that we gladly welcome the news of their high aims and also most cordially agree with the resolution passed at this conference—viz., that it was not advisable for members to use *medical titles* unless the said titles were English and the members were legally entitled to do so. So long as they continue to "make war upon" and to denounce the fundamental principles of their opponents, the allopaths, it is really difficult to see what medical titles they could desire to assume. If it were not for the sadness of the conditions under which "medical herbalists" are mostly heard of, it would be possible to be vastly amused with this unconscious burlesque of the proceedings of other associations.

#### SCOTCH SANITARIANS.

THE eighteenth annual Congress of the Sanitary Association of Scotland has been held at Aberdeen. Delegates from upwards of a dozen Scotch towns were present and Dr. E. Duncan of Glasgow was appointed president of the Association. A number of medical men, sanitary inspectors, borough engineers, and surveyors were present. In view of the forthcoming discussion on the Public Health Bill for Scotland, it is very necessary that sanitary reformers should unite and come to a clear understanding as to what they desire. A complete measure is necessary, and the Scotch sanitary authorities should consist of persons technically qualified. Mr. Peter Fyfe of Glasgow, ex-president of the Association, read a long paper on the necessity of reforming the central sanitary administration of Scotland. He protested against the evils of extreme decentralisation and the optional character of sanitary legislation, and thought the direct responsibility should be placed in Imperial hands. Thus at Aberdeen, as well as at the meeting of the British Medical Association, the cry has gone up for a Ministry of Public Health. This coincides also with the unanimous demand of the French Workmen's Sanitary Congress. The day is therefore, perhaps, not far distant when in every civilised country there will be a Ministry of Public Health. In the meanwhile Scotland has not even a Local Government Board such as exists in England, and certainly in many important respects has not shared in the sanitary progress accomplished in England. There can be no doubt that a Scotch Public Health Act is much needed. The Sanitary Association of Scotland are doing good work in pressing this matter forward.

#### MORE DEATHS FROM GLANDERS.

LAST week we drew attention to the increasing prevalence of glanders and the consequent greater risks of human beings becoming contaminated from diseased horses, giving as some evidence of this the result of a coroner's inquest on the body of a woman who had resided over a stable in which were glandered animals, by which she was infected through using water carried in the stable bucket, it was supposed. On the 1st inst. another inquest was held at Hornsey on the body of a coach-builder who had also succumbed to this loathsome disorder, which he had acquired from contact with a horse he had purchased for a few pounds and which had been allowed to die of glanders. Other cases of death among people from this equine scourge have come to our notice, and considering the extent of the malady among horses, especially in London, it is surprising there are not more coroners' inquests. It is to be apprehended that the disease will become still more extended, for though there is good reason to believe that only a few of the cases occurring are reported by the officials entrusted with the duty of sup-

pressing some of the contagious diseases of animals there are indications that few of the large studs of horses are free from it; while it may be presumed that in the stables of the poorer class of cabmen and carmen infection is rampant. A few days ago one of the largest tramway companies in London was heavily fined for having eight glandered horses at one depôt (a driver in their employment had died from glanders), and an omnibus company has been summoned for the same offence. We have complained of the imperfect measures in force for dealing with the disease and the very lax manner in which they are carried out; and until the authorities are compelled to exhibit more intelligence and energy matters will certainly not mend. All glandered and farcied horses should be at once destroyed, and those animals which have been in contact or cohabiting with them ought to be treated as suspected and isolated from healthy horses. No sales or transfers of horses should be permitted from infected stables or studs, and compulsory notification of the existence of the disease should be imposed on horse-owners and veterinary surgeons. Inspection of infected stables and horses ought also to be carried out by independent authorities, who should also see that contaminated premises are properly cleansed and disinfected. All public water-troughs should be prohibited and horses watered with their own buckets filled from stand-pipes, which might be placed where the troughs now are or where the street water-carts are now replenished. Whatever is done should be done quickly, for the present state of affairs, due more to apathy and indifference than ignorance, is most discreditable and injurious.

#### INTERCOLONIAL MEDICAL CONGRESS.

THE third session of the Intercolonial Medical Congress of Australasia will, as we have already announced, take place at Sydney, N.S.W., from September 26th to 30th inclusive. The president of the Congress is Dr. P. Sydney Jones, F.R.C.S., and Dr. Thomas Chambers is vice-president. There are five sections—viz.: 1. Medicine, including Pathology and Diseases of the Skin, presided over by Dr. Jas. Robertson of Melbourne. 2. Surgery, including Diseases of the Eye, Ear and Throat, of which the president is not yet announced. 3. Midwifery and Diseases of Women and Children; president, Dr. W. Balls-Headley of Melbourne. 4. Public Health, to include State Medicine, Forensic Medicine, Psychological Medicine and Demography; president, Dr. H. H. Whittell of Adelaide. 5. Anatomy and Physiology; president, Dr. H. Brookes Allen of Melbourne. The honorary secretaries of the Congress are Dr. T. P. Anderson Stuart and Dr. Samuel T. Knaggs.

#### CHLOROFORM FATALITY AT A DENTAL HOSPITAL.

AT the Coroner's Court, Dale-street, Liverpool, an inquest was held on the body of Sarah Smith, a woman aged thirty-four. The patient had been suffering from toothache and sought advice at the Dental Hospital, Mount Pleasant, where she was seen by the house surgeon, Mr. Gilmore. She was told all her upper teeth and some of the lower were decayed and required removal. An appointment was made for her to attend on the following day, and the house surgeon requested Dr. J. E. Gemmell to attend to administer an anæsthetic. The woman's husband vainly endeavoured to dissuade his wife from the operation, as he considered she was a very delicate woman, upon whom the shock would act prejudicially. He appears, however, not to have communicated his apprehensions to Dr. Gemmell; and as that gentleman, after examining the patient considered her sound, chloroform was administered. Dr. Gemmell in his evidence says he gave the anæsthetic slowly, and when thirty drops had been taken her pulse became weak and she had an epileptic fit, during which the heart failed. A necropsy re-

vealed a flabby heart and enlarged diseased kidneys. We find no mention made of the posture of the patient or whether her clothing was removed. Dr. Gemmell, as an expert and careful anæsthetist, can hardly be made to bear the brunt of this accident, although we think he probably would have acted wisely to have selected another anæsthetic and, if necessary, had the operation divided. The question whether the patient was a known epileptic appears not to have been asked. Possibly we should understand the fit to have been epileptiform.

#### SIR JOSEPH LISTER.

LAST week this most distinguished surgeon—whose name is synonymous with modern advance in scientific surgery, and who, by his observations and discoveries in the application of the antiseptic treatment of wounds, has added a lustre to British surgery which will never die—closed his career as a clinical lecturer in King's College. According to the regulations of that institution a professor must, except at the special request of the Council, on attaining the age of sixty-five, resign his professorial duties, although there is no apparent diminution of his mental or physical energy. Sir Joseph Lister seems as active and able now as when, twenty-three years ago, in the midst of his early experiments on antiseptic dressings, he resigned his chair of Systematic Surgery in Glasgow to become the successor of Syme in the Clinical Surgery chair of Edinburgh University. The authorities of King's College, recognising the eminence and great ability of this distinguished surgeon, have so far relaxed the rules of the institution that they have determined to retain his services in the wards of the hospital for another year, his duties as a clinical teacher, however, being transferred to younger hands. His last lecture consisted of an excellent *résumé* of the present aspect of the essential parts of the antiseptic treatment of wounds. At the conclusion he spoke with some degree of sadness of the termination of his course as a lecturer, and expressed to the students the hope that in the practice of their noble profession their main object would be to promote the good of their fellow men—a principle which Sir Joseph Lister has ever had present to his mind during his long and brilliant career.

#### THE PROGRESS OF CHOLERA.

WHILST cholera continues to make advances in Eastern Europe there is reason to believe that it is still confined to Russian territory. The outbreaks in Galicia and in Roumania are not only denied, but no further intelligence of an incriminatory character has followed the original statement as to its existence in these countries. Warsaw may or may not be a seat of the disease, but otherwise even Poland seems as yet to be free. Still there is a steadily increasing diffusion of the disease in South-Eastern and in Eastern Russia, the tendency of the diffusion being more and more in the direction of Central Russia. In the Astrakan district and south of the Caucasus some diminution in severity and in the number of those attacked is apparent; but, on the other hand, a very severe outbreak is in progress in the towns bordering on the north-eastern portion of the Sea of Azov and on the river Don, and a number of fairly central provinces, such as Poltava, Voronij, Tambov, Riazan, Orel and Moscow have been invaded. Western Russia as yet remains free. In the Don territory the Government of Rostoff is severely affected, and it is stated that in the last day of July there were no less than 1055 attacks and 447 deaths. The epidemic in the vicinity of Paris shows signs of abatement. Both in Paris, at St. Denis, at Gonesse and at Clichy fresh and fatal attacks are still occurring, but in these places and at Donnoval the tendency seems to be towards a diminution of the outbreak. In Persia the epidemic has markedly subsided at and near Meshed. But

cases have occurred at Yezd and a smart outbreak has taken place on and near the south shore of the Caspian Sea, where Resht, Enzoli, Lahijan and Mengil remain seats of the disease.

#### HEALTH OF MR. GLADSTONE.

WE understand that the illness from which Mr. Gladstone has been suffering during the past week was a feverish bronchial catarrh. On Thursday he was sufficiently recovered to be able to be present in the House of Commons to second the motion for the appointment of Mr. Peel as Speaker of the House.

#### THE OPENING OF PARLIAMENT.

THE thirteenth Parliament of Queen Victoria was opened on Thursday by Royal Commission. The opening ceremony took place as usual in the House of Lords, where there was a large attendance both of members and of the general public. The proceedings, which lasted only a few minutes, were entirely formal. In the House of Commons the Right Hon. Arthur W. Peel was nominated Speaker for the fourth time. The nomination was made by Sir Matthew White Ridley and seconded by Mr. Gladstone, while words of congratulation were offered by Mr. Balfour.

#### GRADUATION DAY AT EDINBURGH.

"*Quæ regio in terris nostri non plena laboris?*" was never more justly the boast of the Edinburgh School than on Monday last, when no fewer than 263 students in medicine, representing every quarter of the habitable globe, closed their academic curriculum, duly qualified to practise throughout an empire on which the sun never sets. The influx of students to her medical class-rooms, which received so great an impetus since the memorable tercentenary celebration of 1884, reached its height two or three years ago, and an unprecedentedly small number of students were registered at the opening of last winter session. So far as can be foreseen the causes of this decline are not likely to be weakened in force. The efficiency of the metropolitan and provincial schools will probably increase. Many of the teaching and examining bodies of these qualifying centres are Edinburgh men, but it is no consolation to that *alma mater* any more than it was to the mythical deity—that it is her own children who devour her. The resuscitated activity of the older English universities is another cause which impairs the prestige of Edinburgh on the side where she used to be exceptionally strong. As Sir G. M. Humphry indicated in a recent paper the preliminary training that can be offered by Cambridge, and, we may add, by Oxford, nowadays is not to be surpassed by any seat of learning north of the Tweed. Nay, we believe the thorough and systematic grounding to be obtained at these schools is, thanks to their tradition of *multum non multa*, intensive rather than extensive culture—a distinct point in their favour, which is gradually becoming appreciated by an ever-increasing public. The formation of a young and energetic university in the north of England and the vigour displayed by the authorities of the University of Durham have also begun to tell their tale. With such formidable competition in the early stage of professional study, Edinburgh presents no countervailing advantages in the opportunities afforded by her clinics, for the number of beds at the disposal of teachers however eminent is unfortunately limited. Practical medicine will seek its qualifying experience rather in the metropolitan and great industrial centres than in comparatively stationary provincial capitals whose population does not multiply in equal ratio.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Berlin.*—Dr. Strassman will undertake the duties of the chair of Forensic Medicine during the next semester, no appointment having been made since Professor Liman's death. Dr. Siemerling of the Charité has been promoted to an extraordinary professorship of Mental Diseases.

*Bern.*—Dr. von Speyer has been appointed Extraordinary Professor of Mental Diseases.—Dr. A. Santi has been recognised as *privat-docent* in Dermatology and Syphilis.

*Buda-Pesth.*—Dr. Ernö Emil Moravcsik has been promoted to an Extraordinary Professorship of Forensic Medicine.

*Cordova (Argentina).*—Drs. Pinero, Mariño and Freyre have been appointed professors.

*Gratz.*—Dr. H. Buchner of Munich has declined the offer of the new Professorship of Hygiene.

*Kazan.*—Dr. Fenomenoff, Extraordinary Professor of Gynecology and Midwifery, has been promoted to an Ordinary Professorship.

*Kiel.*—Dr. Georg Hoppe-Seyler has been appointed to the chair of Medicine.

*Montpellier.*—The chair of Medical Chemistry has been declared vacant.

*St. Petersburg (Medical Academy).*—The principal, Professor Pashutin, having gone abroad, his place has been taken by Professor N. P. Ivanovski. The selection made by the professorial senate of Professor Bellin of Kharkoff for the chair of Forensic Medicine has not been approved by the Government, who have appointed Dr. N. P. Ivanovski, the acting principal, who has hitherto held the chair of Pathological Anatomy, which chair has been conferred on Professor Vinogradoff of Tomsk.—Dr. Trapeznikoff has been recognised as *privat-docent* in Syphilography in the Military Medical Academy.

*Tomsk.*—Dr. Repreff has been promoted to the Ordinary Professorship of General Pathology; Dr. Obratsoff of Kazan has been appointed Extraordinary Professor of Dermatology and Syphilis.

*Vienna.*—The professorial senate have unanimously recommended Dr. Richard Freiherr von Kraft-Ebing *unico loco* as successor to the late Professor Meynert in the professorship attached to the First Psychiatric Clinic in the General Hospital.

*Warsaw.*—Dr. Tauber, Professor of Operative Surgery and Topographical Anatomy, who was deputed by the Russian Government to report upon the English and Scotch Schools of Surgery (*see THE LANCET*, vol. i., 1890, p. 857), has been appointed to the chair of Clinical Surgery.—Dr. Vassilief has been recognised as *privat-docent* in Surgical Pathology and Dr. Sienez as *privat-docent* in Special Pathology and Therapeutics.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Valerian Podwysotski, Professor of Pharmacy and Pharmacognosy in the University of Kazan, at the age of sixty-nine. The deceased professor was originally a lawyer and as such held various official positions; and it was not until he was nearly fifty years of age that he began the study of medicine at Dorpat, where, after taking his doctor's degree, he became assistant in the Pharmacological Institute and *privat-docent* in the University. From thence he was called to the professorship at Kazan. He wrote a good deal in the medical journals on various topics connected with pharmacognosy; amongst which may be mentioned emetin and podophyllin.—Dr. F. L. Thuram, formerly Inspector of the Odessa Sanitary Council, at the age of eighty-five.—Dr. G. W. J. von Düben, formerly Professor of Anatomy in the Caroline Institute, Stockholm, in his seventieth year. After completing his medical studies at Lund in 1844 he was appointed by the Academy of

Sciences to the *Prinz Karl* during an expedition to Africa, India and China. After his return he became Professor—first of Pathological and afterwards of Normal Anatomy—at the Caroline Institute. His chief work is on Lapland and the Lapps. He was also for many years editor of the chief Swedish medical journal, *Hyggea*.—Dr. Hermann von Meyer, formerly Professor of Anatomy in Zurich, at the age of seventy-seven.

WE have to announce the death on the 2nd inst. of a well-known surgeon, Mr. Samuel Armstrong Lane, at the great age of ninety. Mr. Lane was for many years lecturer at the Grosvenor Place School of Anatomy and was elected surgeon to St. Mary's Hospital on its foundation in 1852. It was mainly due to him that the Medical School attached to St. Mary's Hospital was opened in 1854 and to him must be largely attributed the success which it has attained. Mr. Lane was for many years a member of the Council and of the Court of Examiners of the Royal College of Surgeons. He had retired from practice for some years past but to the last he took the greatest interest in all matters relating to his profession. Those who knew "Honest Sam," as he was called by his contemporaries, will remember him as an upright, kind and sincere friend, a sound, thoughtful surgeon, and a practical and earnest teacher.

WE regret that pressure on our space prevents us giving an account of the first general meeting of the British Association held in the hall of the United Presbyterian Synod, Edinburgh. The President, Sir A. Geikie, was introduced by Dr. Huggins, and delivered the presidential address on the subject of the origin of the earth. He referred in this connexion to the views of James Hutton communicated to the Royal Society in 1785, and which Playfair had succeeded in popularising. The views of Werner, of Sir James Hall and Lord Kelvin were subsequently detailed. The address was listened to with the deepest attention, and it was generally regarded as one of the most interesting discourses on geology ever delivered. Lord Kelvin moved, and Lord Provost Russell seconded, a vote of thanks for the address.

ON Capping Day, August 1st, 169 new graduates were enrolled on the scroll of the Edinburgh University. Dr. Pringle presided at the dinner of the Edinburgh University Club at the Holborn Restaurant in the evening. The attendance, considering the time of year, was large. Dr. Pringle made an able speech on the University and on the club itself. The toast of his health was proposed by Sir Edward Sieveking, and heartily responded to. The music and other entertainments of the evening were exceptionally good.

OWING to the spread of the cholera epidemic, an order has been issued from the Ministry of Education of St. Petersburg prohibiting the resumption of examinations in all educational establishments until Sept. 1st next. Also the lectures to medical students in their last term are not to be continued until Nov. 1st, so that students may be free to offer their services in the cholera districts.

THE following names have been added to the list of honorary presidents for the International Congress of Obstetrics and Gynaecology:—England: Drs. Robert Barnes and Thomas Keith, Mr. Lawson Tait and Professor John Wallace. Scotland: Drs. Murdoch Cameron and Berry Hart. Ireland: Drs. Arthur V. Macan and More Madden.

PROFESSOR RUDOLF VIRCHOW was elected Rector of the University of Berlin on Wednesday evening, August 3rd.

THE Queen has been pleased to appoint Sir William Stokes, F.R.C.S.I., Professor of Surgery, Royal College of Surgeons Ireland, to be Surgeon in Ordinary to Her Majesty in Ireland, in the room of William Colles, Esq., M.D., deceased.

THE John Lucas Walker scholarship in Pathology at Cambridge University will shortly become vacant by the election of Mr. Kanthack to the medical tutorship of the University College Medical School at Liverpool.

## THE BRITISH MEDICAL ASSOCIATION. MEETING AT NOTTINGHAM.

IN the Obstetrical Section on Friday, the 29th ult., Mr. Knowsley Thornton opened a discussion on the Treatment of Uterine Fibroid Tumours. He held that the treatment of these depended on their structure, situation and symptoms. If the tumour be small it was absolutely unnecessary even to tell the patient of its existence, as her peace of mind was disturbed. He considered that the treatment by electricity was highly unsatisfactory. In the more severe cases he advocated the operations of hysterectomy or oöphorectomy, and only decided when the abdominal cavity had been opened. Dr. Murphy of Sunderland was in complete accord with Mr. Thornton's statement, but thought that he underrated enucleation per vagina, and related an interesting case where four tumours had been removed from the same woman during a period of five years. Mr. Lawson Tait also agreed with Mr. Thornton's conclusions, but was surprised that he had been so lenient on the electrical treatment. Dr. Horrocks stated that he had obtained very satisfactory results from the electrical treatment and had never seen a death from hæmorrhage in a case of fibroid tumour, and believed the mortality of the operation to be higher than that from the morbid condition. Drs. Tidy, M'Clure, Leith Napier, Michie and Bishop joined in the discussion.

IN the Public Health Section Dr. Tatham of Manchester, the senior medical officer of health present, presided in the absence of Sir Walter Foster, M.P. Dr. Willoughby read a paper on the Nomenclature of Notifiable Diseases. He very justly condemned the tendency to disguise the truth by speaking of "varicella" instead of "small-pox," of "scarlatina" instead of "scarlet fever," "diphtheritic throat" or "croup" instead of "diphtheria," and "septicæmia" instead of "puerperal fever." The result of so doing was that strict isolation and efficient disinfection were neglected. He demanded that definitions should be more strictly applied and suggested that measles be included among the diseases for notification. Dr. Groves said that when certificates were given for the benefit of the Government departments these departments ought to pay for them. Dr. Boobyer testified to the good results from notification and isolation, and Dr. Tew of Nottingham pointed out that in rural districts the medical officers were practically required to assist in the diagnosis of all doubtful infectious cases.

THE interest taken in the question of the admission of women to the membership of the Association was evidenced by the large attendance at the extraordinary general meeting held on the 28th ult. The tone of the speeches of the mover of the resolution (Dr. Galton) to expunge the words from Article 4 of the Association declaring females ineligible and the consequent alteration in the by-laws, and of Mrs. Garret Anderson, who seconded the resolution, was moderate and

their arguments well sustained. We have no doubt that the meeting, in the decisive vote it passed in favour of the resolution, was influenced by the temperate manner in which the subject was brought forward, and although Mr. Lawson Tait hinted at the possibility of the decision being reversed at the confirmatory meeting which is appointed to be held on the 24th inst., we do not imagine that this will happen.

DR. F. A. DIXEY of Oxford read a paper on the Influenza Epidemic of 1891-92 and connected the epidemics with the winter season and special meteorological conditions; while, on the other hand, Dr. Whitelegge argued that the weather had no influence on the epidemic.

THE discussion in the Psychology Section on insanity as a plea for divorce, raised by Dr. Weatherly, although brief, was of importance on account of the fairly unanimous agreement in favour of the plea being sustained in cases of incurable insanity, and after a specified period of time had elapsed since either party had to be placed under legal care and control. Dr. Weatherly in his remarks placed this period at seven years; but Mr. Stewart considered this too short and that it should be at least ten years. The same speaker also pointed out that the legal and medical definitions of insanity were not in accord. It may be noted, however, that such experienced alienists as Dr. Hack Tuke and Dr. Rayner expressed their dissent from Dr. Weatherly's views.

THE outspoken remarks of Professor Gairdner in the Therapeutic Section upon the manner in which new remedies are introduced to the notice of the profession, and the total lack of machinery for scientifically testing their value, will be endorsed by all who feel how much the true interests of the medical art are made to suffer from this growing evil. It is much to be regretted that he should have felt it incumbent on him to resign his position as President of the Therapeutic Committee, but he took the opportunity of the sectional meeting to explain the grounds on which he had acted. He admitted that the main reason for his withdrawal was that the policy which he had advocated—namely, that of obtaining satisfactory inquiries on a large scale upon the action of remedial agents—had not been seconded by the branches; whilst his proposed establishment of local committees of inquiry was frustrated partly by lack of publicity. The reason for this involved considerations of policy outside those of pure scientific inquiry.

THE social functions in connexion with the meeting at Nottingham comprised three garden-parties, two conversations, the annual dinner, and an "at home." A brilliant assembly of the members of the Association and townspeople of Nottingham took part in the conversazione at the University College, given by the Mayor and Corporation. The Association was also entertained by Mr. Leaver, J.P., and Mrs. Leaver at the Hermitage. During the week excursions took place to Buxton and to Lincoln, where Viscount Oxenbridge heartily welcomed the party. At Denton Manor Sir William Welby acted with similar hospitality. Belvoir Castle was visited, and the members were hospitably entertained by the Duke of Portland at Welbeck Abbey and at Haddon Hall by the Duke of Devonshire.

THE annual breakfast given by the National Temperance League to members of the Association took place on the 28th ult. in the Albert Hall and was well attended. The chair was taken by Mr. T. E. Ellis, M.P., and speeches were delivered by the Chairman, Professor Horsley, Mr. Pearce Gould, Dr. Norman Kerr, Dr. M. Cameron and Dr. Cohen.

### THE GENERAL MEETINGS.

WE resume our report of the proceedings of the British Medical Association meeting held at Nottingham last week.

#### EXTRAORDINARY GENERAL MEETING.

##### *Admission of Women to the Association.*

At an extraordinary general meeting of the Association held in the Albert Hall, Nottingham, the question of the admission of women to the Association as members was considered. There was a large attendance, and the tone and feeling of the meeting were very pronouncedly in favour of the proposal. Dr. S. H. GALTON moved that Article 4 of the Articles of Association be altered by expunging the words "No female shall be eligible for election as a member of the Association." Dr. Galton said that out of 140 medical ladies 22 were graduates of the London University. For eighteen years they had borne with this disability. He appealed to them to join with him in removing it from their articles, for it was a blot upon the fair fame of the Association, it was a stain left from the high tide of rank prejudice, and he hoped that the righteousness of Nottingham would wipe out the injustice of Bath.

The resolution was carried *nem. con.*

We understand that an extraordinary general meeting will be held on Wednesday, August 24th, at 2 o'clock, at the offices of the Association, to consider and, if thought necessary, to confirm this resolution.

#### THIRD GENERAL MEETING.

##### *Address in Surgery.*

At the third general meeting Dr. W. H. HINGSTON, of Montreal, delivered his address on Surgery, which was published in our last week's impression. The address was well delivered and well received.

At its conclusion Mr. LAWSON TAIT (Birmingham), in moving a vote of thanks to Professor Hingston, said no better example of the progress of surgery in Canada could have been presented to them than in the person of Professor Hingston. The professional work of the Dominion was quite equal to anything in Europe.

Mr. JOHN CROFT seconded.

##### *The Profession and the Local Government Board.*

Mr. D. B. BALDING moved, in accordance with notice, "That, in the opinion of this Association, the decision of the Local Government Board in reference to the case of the late Mr. Walters of Cheltenham was unjustifiably severe, and that it is incumbent on this Association to use its best endeavours to procure a reconsideration of the case."

After conversation a suggestion to refer the matter to the Parliamentary Committee was agreed to.

The meeting afterwards adjourned.

#### FOURTH GENERAL MEETING.

##### *The Address on Bacteriology.*

The interest of the annual meeting culminated in the able and eloquent address which was delivered by Dr. German Sims Woodhead. At its conclusion—

Surgeon-Colonel HARVEY moved that the best thanks of the Association be given to Dr. Sims Woodhead for his address, which was full of interesting information. Bacteriology had so developed that it required experiments to pursue it. The great *raison d'être* of the profession was to heal the sick, but the love of science would not give a man food and raiment or help him to meet the exigencies of life. The man, he said, who teaches the bacillus should live by the bacillus.

Dr. EDDISON (Leeds), in seconding, said this was the first occasion on which an address on this subject had been delivered at this Association. What struck him about Dr. Woodhead's address was the way in which he constantly emphasised, not what he had done, but what other men had done.

##### *Experiments on Living Animals.*

Mr. HUTCHINSON then moved a resolution in the following terms: "That this general meeting of the British Association records its opinion that the results of experiments on living animals have been of inestimable service to man and to the lower animals, and that the continuance and extension of such investigation is essential to the progress of knowledge, the relief of suffering, and the saving of life." He said it was scarcely necessary to move a resolution which he believed to be a simple

truism. He thought that the agitation which prevailed some twenty years ago against vivisection was rapidly and steadily dying out. Most of them had been brought into contact here and there with little attempts of vexatious opposition, which sometimes fell with peculiar severity upon one or two hapless individuals. There was about to be held a congress of clergymen at which this subject would be brought forward, and medical men had been invited to take part in the discussion. He had not the slightest objection to clergymen discussing that question. Some of the leading members of the profession had been invited to take part in the discussion, but they had declined. Sir James Paget had declined, and so had Sir George Humphry, on the ground that the discussion was not one in which those educated in medical matters could meet clergymen on common ground. They were right; they did not object to its being discussed, but it was useless to talk to people, however well informed on other matters, on a subject of which they could have but little knowledge. The British Medical Association, he hoped, representative as it was of all branches of the profession, would pass this resolution unanimously. They were not personally engaged in this work, but they could understand what valuable results were obtained from it. It was a matter of duty and of justice that the Association should stand by those who had performed experiments and who had thereby incurred considerable odium, and perhaps in some instances even damaged their reputation and success in life, in consequence of their appearing in public as advocates of this method of investigation. He was one who for twenty years past had never made any experiment on living animals. He had nothing to do with that department of investigation and he spoke for the large majority of those present at this meeting; but it would be a matter of cowardice if they stood aside and did not back up thoroughly those who were engaged in the pursuit of the clinical and particular aspects of the profession, or if they failed to express their deep gratitude to those investigators. As practical men the profession availed themselves of their discoveries. They applied their knowledge, and therefore they were bound to stand shoulder to shoulder with them. They were not only doing that which is not cruel, but they were doing their duty and conferring inestimable services upon the progress of science. They claimed to go before the laity and say the medical profession is a profession of humane men to whom every form of cruelty is detestable. We are fairly well informed as to the scientific aspects of this question. It is, indeed, part of our duty to be informed; and it is only common sense that you, the laity, who do not possess the especial information that we do, should listen to us. He did not object to legitimate forms of restriction. Indeed the medical profession was glad, if there should be some erratic individuals in whom the sentiment of humanity was lost in a matter of this kind, to have judicious State legislation. In this there was no cruelty, because nothing came under that definition which had for its object the diminution of suffering. Sir William Gull was asked by a lady if he did not consider experiments on animals as cruel. "Madam," he said, "there is no cruelty comparable to ignorance." Of course there would be in the medical profession a very small minority who would object.

The resolution was carried unanimously. This concluded the business of the general meetings.

## THE SECTIONS.

### MEDICINE.

#### *Ascites.*

Dr. W. J. TYSON read a paper on Ascites. "In reading over the subject of ascites in various text-books there is an absence of a good description of those cases which for a better name may be called 'simple ascites.' There always will be, and I think there ought to be, an objection made to the word 'ascites' without an accompanying distinctive adjective designating the cause of the ascites. In the same way one should object to the word 'meningitis' or 'peritonitis' as a final diagnosis. This is not at all a matter of sentiment, for the constant use of the above words as indicating a disease instead of a symptom lead some men to be satisfied with this, and hence in many cases the real cause of the disease remains untreated. The class of case to which I wish to call the attention of the members is that in which no cause can be discovered to account for the ascites, and yet with ordinary treatment of diuretics and aperients,

with tapping if necessary, recovery takes place. Two cases lately under my care at the Victoria Hospital, Folkestone, will illustrate the class to which I am referring. A. B—, a boy aged sixteen, was admitted on July 6th, 1891, with a good family history; he was quite well until his present illness, which commenced two months back with enlargement of the abdomen, which had been gradually increasing. On admission there was very considerable ascites, the abdomen measuring at umbilicus thirty-one inches in circumference, and between the umbilicus and ensiform cartilage thirty-three inches. There was no valvular disease, but the heart's apex was pushed up, beating opposite the nipple. There were signs of pleuritic effusion in both pleural cavities as high as the angles of the scapulae. There was no œdema in the legs or scrotum. The urine was non-albuminous, pale, with a specific gravity of 1006. The treatment adopted was the outward application of linimentum hydrargyri, whilst internally the patient was given tincture of digitalis with acetate of potassium; he was kept in bed. After a month all the ascitic fluid had disappeared and he became apparently quite well and has remained so since. The second case was that of a woman aged twenty-two, who had been married for six years, and had never had any children or any miscarriages. Her family history is a good one; her father, mother, two brothers and three sisters are all living and well. In 1884 she had typhoid fever, at which time the abdomen swelled, but went down again and, she stated, it has remained more or less swollen up to the present time of admission into Victoria Hospital on May 3rd, 1892. On admission the abdomen measured in circumference at the umbilicus thirty-seven inches and a half and it was very much distended. No cardiac, lung, or kidney disease could be discovered. On account of the great distress in breathing it was necessary to use paracentesis on May 10th, when twenty-two pints of ascitic fluid were drawn off. After the operation the abdomen was carefully examined for any enlargement &c., but nothing was found to account in any way for the ascites. The circumference was now twenty-nine inches at the umbilicus and has remained the same up to the present time. She was treated from the commencement of her stay in the hospital with digitalis, iodide of potassium and sulphate of magnesia, and Addison's pills night and morning, but with no result until after the tapping, when the urine passed, and was rapidly increased in quantity. The two foregoing cases are only examples of a large number in which the ordinary explanations of ascites are absent, for there is no cardiac, pulmonary, renal or hepatic disease present which would account for the ascites—not that we must forget that cases of ascites, when due to the foregoing causes, frequently get well, for I feel sure that our hospital experience often is fallacious as regards prognosis, inasmuch as the disease upon which the ascites depends occurs in subjects of much lower vitality, and therefore less under the influence of treatment, than those met with in private practice. I know of two cases of ascites, one due to kidney disease, the other due to cardiac disease, in which immense distension of the abdomen existed for some weeks. In the first there has been no return of the dropsy for six years, although a large quantity of albumen is still passed; and in the second there has been no return for a twelve-month. But in the so-called simple cases, to which I am particularly referring, the prognosis is very hopeful. Of course there is a cause to account for the ascites in the cases, but it is very difficult to find. Some of these, no doubt, are tuberculous in origin, others perhaps are due to that most convenient of causes—namely, exposure to cold. Still the important fact remains that there are a fair number of cases of ascites to which no cause can be assigned and which on treatment get perfectly well."

### SURGERY.

#### *Discussion on the Surgery of the Liver and the Gall-bladder.*

The discussion in the Surgical Section of this subject took place on Thursday morning and was opened by Mr. Mayo Robson. He said his conclusions were based on a personal experience of seventy cases of operation and upon many others in which no operation had been performed. He divided his paper in two sections, the first dealing with those injuries and diseases of the liver amenable to surgical treatment, and the second with gall-stones. Injuries of the liver attended by free and dangerous hæmorrhage can be successfully treated by exposing the injury either through an already existing wound or by an abdominal incision and plugging the liver and wound with iodoform gauze—a drainage-tube should

be afterwards inserted and the external wound closed. Abscess of the liver is a more common disorder than is generally believed. He had met with several cases and had dealt with some of them by operation. The diagnosis of this condition was always difficult and sometimes impossible until the abdomen had been opened. When the abscess has been found by an exploring needle the abdomen should be opened and the liver carefully sewn to the parietal peritoneum before opening the abscess cavity. In some cases this is impracticable, and then the cavity of the abscess should be cleaned carefully and thoroughly packed with iodoform gauze through the open external wound. Mr. Mayo Robson showed a simple and rapid way by which a drainage-tube can be introduced into an abscess of the liver where a patient is too ill to allow of the more systematically arranged operation. Free drainage is the real secret of success in these cases. Abscesses of the liver which have opened into the pleura, lung, pericardium &c. should be treated at their source by hepatotomy. A subphrenic abscess may be best opened through a lower intercostal space. Hydatid cysts are most safely dealt with by hepatotomy. Statistics prove that this operation gives better ultimate results than puncture. Other varieties of cysts are met with—examples of which were given in detail and the nature of some of which it is difficult to understand. Excision of a part of the liver has been successfully practised and may be called for in a limited number of cases. Mr. Robson thought that the elastic ligature would be found of service in this operation. He approved of the principle of exploratory working in all doubtful cases, and referred to some in which tumours, solid in their nature and malignant in their naked-eye appearances, have entirely disappeared after this procedure. Mr. Robson had operated in more than fifty cases of cholelithiasis with a mortality of three cases only, and each of these had been complicated by malignant disease. None of his simple cholecystotomies had died at all. He referred at length to the many disorders for which gall-stones are mistaken and gave examples of such cases which had been under his care. It was of first importance to locate the exact presence of gall-stones, and he thought in most cases this could be done. He referred to the occasional occurrence of pain in the left side and in the left scapula, and explained this fact by the presence of adhesions to the stomach. Sounding for gall-stones by acupuncture needles he regarded as dangerous, and aspiration of a distended gall merely for purposes of investigation was not to be commended. He referred to the free bleeding, which is often seen during operations on jaundiced cases, and recommended the previous administration of chloride of calcium as an internal hemostatic. With regard to the operation of cholecystotomy, he thought the operation in which the opening in the gall-bladder was sewn to the external wound was better than the ideal operation, in which the opening in the bladder was sewn up and the whole returned into the peritoneal cavity. When it becomes necessary to open the cystic duct, suture of the opening to the parietal peritoneum or the introduction of a large drainage-tube are the best procedures. He does not recommend supra-pubic drainage, as advocated by Mr. Knowsley Thornton. Gall-stones in the common duct may be crushed with fingers or forceps and left to pass into the duodenum. Cholecystectomy is occasionally a necessary operation, but should not be performed unless absolutely indicated, and when jaundice is present it should never be performed. Cholecystenterostomy has been successful in his hands and occasionally called for. It is best made into the duodenum and by means of a new form of decalcified "bobbin," which he described.

Mr. LAWSON TAIT agreed entirely with the views enunciated by the previous speaker, many of which were confirmatory of views advanced by himself a few years ago. Difficulties of diagnosis are constantly encountered and stand in the way of treatment. Hepatotomy is a safe operation if performed early enough. Delay gives the operation its dangers. Resection for cancer had no sympathy from him. In his operations for gall-stones death had only occurred in cases where cancer was also present. Gall-stones do not form again after operation, and cholecystectomy is therefore rarely necessary. He was glad that Mr. Robson had confirmed a previous statement of his (Mr. Tait's) that certain tumours of the liver which looked like cancer occasionally disappeared in a mysterious way after a simple exploratory operation. Mr. Tait presented a table of cases which showed twenty-one exploratory incisions with four deaths, eighteen hepatotomies with two deaths, and seventy-one cholecystotomies with four deaths.

Mr. JORDAN LLOYD called attention to the importance of

diagnosing before operation, not only the presence, but the exact locality of gall-stones, for the reason that the dangers of cholecystotomy depend more upon the position than the number, size or chemical composition of the stones. Cholecystotomy is a safe operation so long as the calculi can be removed through the opening made in the gall-bladder; but if the common duct has to be opened because of the position of the stone and the contracted condition of the gall-bladder the risks of the operation are enormously increased. Such a diagnosis can usually be arrived at by bearing in mind, firstly, that hepatic colic without subsequent jaundice and without a tumour, as a rule, locates a stone strictly within the gall-bladder; secondly, that hepatic colic, without subsequent jaundice, but with a subsequent tremor, locates a stone within or at the mouth of the cystic duct; thirdly, that the hepatic colic, with ague-like paroxysms, rigor, high temperature and sweating, followed by jaundice, locates a stone in the common duct. If a tumour be not present the gall-bladder is probably puckered up by chronic inflammatory changes. Persistent jaundice, generally, is the equivalent of malignancy.

Mr. CHILCOTE thought that in abscess of the liver the method of wound dressing was of great importance. He said that most liver abscesses were divided up by soft interlacing trabecule, which required thoroughly breaking down before free drainage could be secured.

The PRESIDENT said that these cases are, as a rule, brought too late under the surgeon's notice. He thought that the present satisfactory results should encourage physicians and practitioners to call in the aid of the surgeon at an earlier period.

Dr. GEORGE HARLEY said that physicians and surgeons had a common object—to cure disease; and in liver disorders each of them looked at their cases from a different standpoint. Surgical operation should be the very last measure to be adopted. He believed that the large majority of liver cancers were secondary to gall-stones.

Mr. BRUCE CLARKE referred to the two methods of treating hydatids by tapping and by drainage. He called attention to the fact, too, that hydatid cysts could be shelled out of the liver substance if they had not been left long enough to form strong adhesions. The early operations in these cases would always be the more satisfactory if only for this reason.

Mr. F. EVE referred to a case of actinomycosis of the liver which he had diagnosed during life and which might have been removed by operation. He referred also to a curious form of loculated abscesses which he had seen, and suggested that these tumours which disappeared after simple exploratory operations might have been navi.

Mr. MAYO ROBSON, in replying, thanked the members for their patient hearing. He said that when an incised duct cannot be closed by suture drainage with a large tube will suffice. The mortality of all cholecystotomies ought to be less than 5 per cent. The tumours which disappeared could not be navi for the reason that they were quite hard, like scirrhus when examined with a finger or a needle.

The discussion then terminated.

A paper was read by Mr. EWENS on Overgrowth of the Inner Tuberosities of the Tibia as a cause of Genu Valgum independent of Elongated Inner Condyle of the Femur, illustrated by photographs. Having alluded to the silence of some eminent surgical authorities on this subject, and the slight reference as regards the distinction between this affection and other forms of genu valgum made by other writers, Mr. Ewens directed attention to two cases by which his observations were illustrated, in which the inner tuberosities of the tibia were enlarged and elongated without any corresponding change in the inner condyle of the femur.

Mr. E. LUKE FRIBER read a paper on the Treatment of Scoliosis. He stated that in his opinion the two chief causes of scoliosis were: bad positions acquired at school or work during childhood and adolescence, and muscular debility. In Birmingham he found that a large number of cases occurred among the working classes, and to these cases he gave the name of "Trade Curvatures." He held very strongly that when once a curvature was developed to the extent of bony alteration no cure could be effected, although the curvature could be prevented from getting worse. The principles of treatment which he adopted were those enunciated by Dr. Roth, consisting in the practice of what might be called medical gymnastics. This treatment, which he had for years adopted, could not be carried out satisfactorily in Birmingham, in consequence of the neces-

sarily imperfect hygienic conditions of a large town, but the very best results were obtained from it when practised at Llandudno, where he now resided. The treatment consisted in an improvement of the general health in the correction of bad postural positions and in the re-education of weakened muscles by systematic exercises. Mr. Preer gave a detailed account of the exact course of muscular training through which he caused his patients to pass.

#### OBSTETRICS.

##### *Post-partum Hæmorrhage.*

Dr. HERMAN, on opening a discussion on the subject of post-partum hæmorrhage, emphasised the importance of compression of vessels as the rational means of stopping hæmorrhage. For prevention of hæmorrhage the main points were (1) avoidance of delivery when the uterus was inactive; (2) careful supervision of the third stage of labour. In treatment he advised (1) kneading by the abdominal hand. If this did not succeed, (2) putting the hand in the uterus to make sure that it was empty; (3) washing out the uterus with hot water. If these means failed, persistent bi-manual compression of the uterus. The application of cold he considered a temporary substitute for kneading. Putting the child to the breast was a useful and harmless adjuvant. The injection of perchloride of iron brought with it danger of (1) sudden death from distension of the uterus, (2) embolism, (3) peritonitis, (4) septicæmia. It left the uterus filled with clot. Although its effect was to check hæmorrhage, yet it sometimes failed. It was therefore neither safe nor certain. Packing the uterus with gauze sometimes failed, brought with it danger of entrance of air into veins, and the uterus could not properly contract when filled with gauze.

Dr. JOHN BYERS read a paper discussing the question, "Does Chloroform promote Post-partum Hæmorrhage?" In this paper the author, while pointing out the great advantage of chloroform in obstetric practice, draws attention to the fact that it is not so frequently employed by accoucheurs as might have been thought to be the case. In explanation of this circumstance two reasons are assigned and discussed:—1. The deterring effect produced on the profession by the alarming and disastrous results which have too often followed the use of chloroform in surgical practice. 2. Its alleged effect in promoting post-partum hæmorrhage. In support of this view he discusses the two arguments usually put forward—(a) The teaching of authorities; (b) personal experience. In reference to (a) he shows that there is no unanimity amongst teachers on this point, and hence the question can only be settled by (b) personal observation and experience. He shows the fallacy of the argument that, because chloroform was given and hæmorrhage followed, it was cause and effect—the *post hoc ergo propter hoc* style of reasoning—and argues that the great majority of cases of alleged flooding after delivery occurring when the anæsthetic was used can be explained as being due, not to the chloroform, but to rapid delivery and to a want of proper management of the third stage of labour. Those who take the other view must, when they report cases, give all the details of them—such as the age of the patient, the number of her previous confinements, the extent to which, and the method by which, the anæsthetic was given, the cause for which it was employed and the plan of delivery and the method employed in the management of the third stage of labour. In conclusion the author gives his own experience of an extensive and increasing employment of chloroform in obstetrics, which warrants him in stating that this anæsthetic has no effect in causing post-partum hæmorrhage, provided that in all cases care is taken not to effect delivery too rapidly and also to manage the third stage of labour according to modern teaching.

In the discussion which followed Dr. WALTER (Manchester) had much pleasure in hearing Dr. Herman's paper, and as so many members wished to take part in the discussion he would confine his remarks to three of the methods of treatment referred to by Dr. Herman in dealing with post-partum hæmorrhage arising from inertia of the uterus. 1. The intra-uterine injections of hot water was a mode of treatment which he had frequently tried; and whilst in many cases it would be found to act efficiently yet it was not always reliable. Much, however, depended upon exactness in the temperature used, as had been amply proved by the experiments of Max Rüinge on animals, which showed that uterine contractions followed if the temperature of the water used was from 112° to 115° F., but if the temperature was raised

above 120° F. no uterine contraction followed, the muscular fibre remaining paralysed. In those cases where hot-water injections failed Dr. Walter had often found that injections of vinegar and hot water in equal parts were followed by permanent uterine contraction. 2. Dr. Herman had spoken of the difficulty attending the use of electricity; this he had also found to be the case until he discarded all the ordinary batteries and used instead a small, but very powerful, magneto-electric machine, made for him some years ago by Weiss, with an intra-uterine electrode that unscrewed into four pieces and fitted into the box. The coarse interruptions produced by this machine had a remarkable power in inducing uterine contraction. 3. Intra-uterine plugging with gauze was not a method which he could advise, unless after abortions or miscarriages, when the expansile power of the uterus was limited. In one case, in which he had seen the uterus plugged after labour at full term, the uterus expanded after the plug had been inserted and hæmorrhage recurred. On removing the plug and washing out the uterus with hot water and vinegar the hæmorrhage was at once checked.

Dr. CULLINGWORTH thought there was a danger of the main object of the discussion being lost sight of. It was of great importance that we should have clear and definite rules for treating ordinary cases of post-partum hæmorrhage. The first step to take is to endeavour to excite uterine contraction by external manipulation. If this fails the aseptic hand should be passed into the interior of the uterus, the cavity emptied and the external manipulations supplemented by internal. Should the hæmorrhage continue the next means to employ is injection of hot water, at a temperature not lower than 110° F. The water should be injected in considerable quantity and the nozzle should be inserted sufficiently far to ensure the whole inner surface of the uterus being bathed with the fluid. It will not be often that these methods will be found insufficient to check the hæmorrhage or that recourse will be necessary either to plugging the uterus or swabbing with iron. He wished to enter a protest against Dr. Murdoch Cameron's suggestion that the vagina should be plugged. He had hoped that this method of treatment was as obsolete as it was dangerous. He agreed with Dr. Byers as to the absence of any clear evidence that chloroform exerts any influence in promoting post-partum hæmorrhage.

Dr. ROBERT BARNES advocated the seizing of the uterus with the hand, the injection of hot water, and in extreme cases of perchloride of iron, which he had found of the greatest benefit. He was satisfied of the benefit to be got from ergot.

Dr. WILLIAM DONOVAN said: "I have practised obstetrics continuously for the past twenty-four years, and am able to say that I have not had in that time a serious case of post-partum hæmorrhage. I look on post-partum hæmorrhage as the revenge of an outraged uterus. The uterus, like other muscular structures, when overstrained loses for a time the power of contracting. If the uterus is allowed to go on contracting after the fœtus has ceased to advance with the pains we are preparing the way for an attack of hæmorrhage. If we give ergot to force the uterus to still more active contraction we are only increasing the danger. In my opinion ergot should never be given in a case of difficult labour, and I have no hesitation in expressing my strongest disapproval of the heroic (to say the least of it) manner in which certain practitioners have recommended its use. I consider ergot not only useless but absolutely dangerous, and, given in the enormous doses recommended by certain men, improper and unscientific. When I find that the head does not advance with the pains and that there is an arrest for, say, half an hour, I invariably put on the forceps and deliver the head; then I give the uterus time to contract on the trunk and lower limbs, assisting their expulsion gently. The legs and feet I allow the uterus to expel without assistance. If this plan is followed the uterus will contract and expel the placenta. I think it a safer and better practice to allow the uterus to do this itself; and if this is done I think there will be little danger of post-partum hæmorrhage. The sudden emptying of the uterus by a quick withdrawal of the lower limbs of the child and worrying of the uterus immediately after by compression or expression all favour hæmorrhage. I am inclined to agree with Dr. Playfair when he says that 'he looks with suspicion on the obstetrician in whose practice post-partum hæmorrhage occurs often.' The points I wish to lay stress on are—Never force a willing uterus. Help it all you can; do not worry it with ergot. If the

child remains unmoved, with pains of fair strength, put on the forceps, do not hurry over the delivery of the body and limbs, and leave the placenta alone; do not press and knead and worry the tired uterus. If you are inclined that way give a dose of ergot. When the head is delivered give the uterus time to recover after the strain of expulsion, so that it may gather contractile power to expel the placenta, or, at least, to force it into the vagina; after that take it away. As to the question of chloroform increasing the tendency to hæmorrhage I think there is no ground for the fear. Do not give ergot, it is a bad and dangerous substitute for the forceps. Remember the old saying, 'Never spur a free horse,' and of all things, assist nature and do not force her, and when you do assist, do not half do it—do not allow the uterus to exhaust itself so that it loses its power to contract, and, far worse, have post-partum hæmorrhages, and do not worry it with compression and kneading, or it may take its revenge and relax.'

Mr. E. STANMORE BISHOP (Manchester) said: The question of post-partum hæmorrhage was one of what was called, in surgical parlance, concealed hæmorrhage, and in treating it a surgeon would naturally first think of a tourniquet. The ultimate process upon which we depended was the deposition of fibrin in the open vessels, and it was useless to expect this as long as the full force of the heart's action was driving blood through them. Although blood was apparently coming from innumerable jets the supply to the uterus, from which it was derived, was only through two main arteries, the uterine and ovarian. The uterine—the larger—arose from the internal iliac, and therefore was controllable by pressure upon the aorta near or above the sacral promontory, the most easily reached point. The ovarian artery, although arising higher up, was practically in the grip of the surgeon who held the fundus uteri. If, therefore, the ulnar surface of the closed left hand be pressed firmly against the aorta, compressing it against the spine, whilst the right manipulated and kneaded the uterus, the whole blood-supply was under control. This was not mere theory, the speaker having seen the blood gushing freely one moment and stopping suddenly as though the tap had been turned off directly this manoeuvre was executed; and this not once, but more than fifty times in cases where the patient was utterly blanched by the suddenness and severity of the flood. The aortic pulse, which could scarcely be felt at first, gradually came back, becoming slowly firmer and stronger, until it beat with normal force against the proximal side of the hand; whilst no loss, or scarcely any, occurred whilst the pressure was kept up. This procedure was productive of several good results. It gave time to the patient to recover; it dammed up the blood in the upper half of the body, so keeping up the vitality of the more important organs; it gave time for fibrinous plugs to form in the patent vessels; it allowed the exhausted muscular fibres of the uterus—the ligatures, so to speak, of the vessels—time to recover their contractile powers, and it permitted the surgeon, if necessary, to apply with more ease and power any local hæmostatic measures he might deem advisable.

Dr. WALTER of Manchester read a paper on a case of Tubal Gestation in which both tubes were gravid, with recovery after operation, and showed the specimen as well as drawings. On August 7th, 1891, Mrs. S—, aged twenty-nine, was admitted into St. Mary's Hospital for Women, complaining of abdominal pain, painful defecation and painful menstruation. The patient had been married ten years and had had five pregnancies, the last four years previously. In July she menstruated as usual, but the periods in May and June were missed, during which months she suffered from morning sickness, pains in her breasts and abdominal pain during defecation, and in the month of June she could not leave her bed. The physical signs on her admission to hospital proved the uterus to be normal in size and position, but its mobility was slightly impaired. In the left broad ligament and close to the uterus was a mass the size of an orange, but owing to the tenderness that existed the swelling could not be accurately outlined. No swelling existed on the right side. Abdominal section was recommended, but before the operation could take place the hospital had to be closed for repairs, and the patient returned home. She again came to the hospital on Dec. 14th, 1891. There was no alteration in the physical signs, and she menstruated regularly. She was suffering, however, from bronchitis, and her cough was very severe and frequent; on this account the operation was again postponed. On Feb. 19th,

1892, she was readmitted and it was then found that she had missed a period in January, but began to menstruate on Feb. 17th, or two days before admission, and that during the seven or eight weeks of amenorrhœa she again suffered from sickness. On Feb. 21st, her period being over, a physical examination was made; the swelling in the left broad ligament was found to exist as before, but in addition a swelling could now be felt on the right side and behind the uterus. The uterus was still normal in size. It was decided to operate on Feb. 26th, and on the afternoon of Feb. 25th the patient was given some aperient medicine; during the evening her bowels acted five times, and at 11 P.M. she was suddenly seized with abdominal pain and vomiting; her pulse was 110 and very weak. She quickly rallied and, with the exception of increased abdominal tenderness and rigidity of the muscles of the abdominal wall, no alteration was found to have taken place in the physical signs. The next morning abdominal section was performed and a quantity of fluid and clotted blood was found loose in the peritoneal cavity. Both tubes were found enlarged, distended with blood-clot and closely adherent to the neighbouring parts. The uterus was normal in size and position. The right tube and ovary were removed together. The tube on the left side was removed also, but the ovary was not disturbed, it being closely adherent to the side of the pelvis at some distance from the tube. The abdominal cavity was irrigated with hot water and a glass drainage-tube inserted. The abdominal incision was closed with silkworm-gut sutures, and dry dressings of corrosive sublimate wool were applied over the wound. The patient made an excellent recovery and left the hospital on March 26th. On July 28th, 1892, she reported herself to be very well, and stated that soon after leaving the hospital she was able to perform her own housework and that she menstruated regularly. In a note appended to the paper Mr. Bland Sutton says: "As far as my knowledge of the subject extends this is the first indisputable example of a tubal pregnancy occurring concurrently in both Fallopian tubes of the same individual. There are three cases in which it was probable that this accident had happened, but the facts are not completely demonstrated—viz., Dr. T. Rowan (*Australian Medical Journal*, 1890, p. 265), Mr. A. Doran (*British Medical Journal*, 1891, vol. ii., p. 789), and Dr. Savage (*British Medical Journal*, 1892, vol. i., p. 556)."

P.S.—Since the above report was written an undoubted case of bilateral tubal pregnancy has been published by Mackenrodt. (*Zeitschrift für Geburt. u. Gyn.*, Bd. xxiii., Heft i.; *Die Verhandlungen der Gesellsch. für Geb. u. Gyn.*, at Berlin, s. 301.)

#### *Morbid Conditions of the Fallopian Tube.*

Dr. CULLINGWORTH gave a special lantern demonstration on some of the more common Morbid Conditions of the Fallopian Tube in the physics lecture theatre of University College. The room was well filled. The slides, most of which were coloured, were about twenty-five in number, and consisted of illustrations taken from actual specimens of the conditions known as hydro-salpinx, pyo-salpinx, and hæmato-salpinx; also of tubercular disease of the Fallopian tube, of suppurating tubo-ovarian cysts, and of tubal gestation. The drawings had for the most part been made immediately after the removal of the parts from the body by operation, and therefore while the tissues retained their natural colour.

#### PUBLIC HEALTH.

##### *Hospitals for Infectious Diseases.*

Dr. II. TIMBRELL BULSTRODE, of the South-Western Fever Hospital, London, read a paper on Hospitals for Infectious Diseases. He condemned wooden and corrugated iron huts, and, while demanding better hospitals, thought there should be a graduated charge for admittance. He believed that in many fever hospitals the nursing was not good and many of the nurses had no special training. The utmost should be done to tempt patients to come to the hospital. Dr. Bulstrode concluded by advocating the creation of a Ministry of Public Health.

Dr. BOOBYER, Medical Officer of Health of Nottingham, said that payment for admission to the fever hospital had been tried and found to be a failure. It was now left to the goodwill and good feeling of each patient, and one gentleman had recently and voluntarily given three guineas a week. But at Nottingham there was the strongest feeling

against accentuating class distinctions, yet they tried to put the clean, respectable, decent patients in one ward. The removals of notified cases amounted to 85 per cent. last year; the number of fresh cases in the houses from which patients had been removed amounted to only  $\frac{3}{4}$  per cent.

Dr. HILL of Birmingham thought the idea of payment for fever hospitals altogether exploded.

Dr. GROVES (Isle of Wight) pointed out that in health resorts they were especially liable to the introduction of infectious disease, and yet its notification might frighten people away and ruin the locality.

Papers were read by Dr. W. L. HUNTER on Small-pox in Pudsey a Century Ago; Dr. G. SCOTT TEW on Endemic Typhoid Fever; Dr. J. C. THRESH, on Notification of Erysipelas and Puerperal Fever.

Dr. R. PRINGLE mentioned a district in India where 95 per cent. of all the population was marked with small-pox; but where vaccination was practised that malady had been kept out. These assertions were confirmed by Surgeon-Colonel Hardy.

#### PSYCHOLOGY.

##### *Neural Action corresponding to the Mental Functions of the Brain.*

Dr. FRANCIS WARNER opened the discussion on the above subject. He argued that during the period of inhibition there occurred a bracing together of those nerve cells of the cortex which were concerned in the production of the microkinesis, and that this bracing together was antecedent to the purposive movement which followed. When a bright object was placed before an infant a few months old, upon many successive occasions, it was found that the purposive movement to clutch at it which followed the exhibition of the object occurred much more rapidly after a few days than at first, and this, he concluded, was dependent upon the development of a more intimate connexion between nerve cells than had originally obtained.

Mr. BEVAN LEWIS (the President of the Section) considered that Dr. Warner's conclusions were based upon sound observation and were substantially correct. He also pointed out that these signs of attention were of real use in diagnosis, that it is characteristic of alcoholics that the signs of attention are exaggerated, that attention itself cannot be long maintained, and that these points are of assistance in diagnosing this condition from general paralysis of the insane, for in the former there are marked twitchings about the brow and upper part of the face.

Dr. MICKLE contended that the action which resulted from a stimulus was largely dependent upon congenital structure. The mechanism concerned in swallowing was inherited from parents, and in like manner was that concerned in producing the more complex movements to which allusion was made.

Dr. RAYNER made a few remarks.

Dr. CAMPBELL maintained that will and attention could be brought into one line. In support of this he stated that all parts of the body are represented in the higher cortical centres, and that if we examine carefully the accompaniments of any simple act of attention certain changes would be found in the part to which attention is drawn. He claimed that during a voluntary act attention was emphatically directed towards the muscles, and that consequently attention and volition are both related to the dynamic changes in the parts.

Dr. WARNER, in replying, stated that at birth idiots did not present normal spontaneous movements, and that in these subjects they were either absent or irregularly grouped together, and spasmodic in character.

Dr. HARRY CAMPBELL read a paper upon Minor Psychological Disturbances in Women. He began by saying that cases such as his were about to describe came to the London hospitals in their thousands, and that they very rarely if ever became insane. Such patients were, as a rule, not hysterical. The symptoms which he described in detail were as follows:—(1) Depression of spirits, worse in the morning, often relieved by weeping. He discussed the reason why such depression should be worse in the "cold grey dawn," as one of his patients expressed it, and considered that it was largely due to the antecedent sleep. In one-third of his cases, however, depression was worse in the evening. He considered that the principal cause of the symptoms was abnormality of blood plasma and of blood pressure, and that ptomaines and other morbid bodies had an important

influence. He discussed the question as to how far the nerve-cells themselves were healthy. He thought that recovery depended rather upon the building up of impoverished blood than upon the repair of any defective nerve structure.

Dr. URQUIHART (Perth) thought that the study of borderland cases was of the utmost value in the study of insanity. In speaking of morning depression he alluded to the sad and gloomy words of self-depreciation used by Ruskin in concluding one of his works, which words were written in the small hours of the morning.

Dr. ROBERTSON (Edinburgh) alluded to the anabolic activity of the cortical cell during sleep, so that the cell was built up again for further work. He argued that under morbid circumstances the contraction of the bloodvessels might hinder access of red blood discs to the cells, the capillaries being so contracted that the nerve-cells might be in part deprived of oxygen during the hours of sleep, resulting in exhaustion of the cells. This might be the cause of the depression and mental pain occurring shortly after sleep.

Dr. FRANCIS WARNER thought that delusions and ocular illusions were more common than Dr. Campbell had stated, and that hospital patients withheld them for fear that they should be considered insane.

Dr. DUNN (Wakefield) considered that in hospital patients the principal cause of the depression was a deficiency in the supply of food-stuffs to the brain, as in the morning food had not been taken for a long time, and that he had found an early breakfast valuable in relieving depression.

Dr. JOHNSTON-LAVIS (Harrogate) said morning depression was common in Italy where late breakfasts were taken. He found that it was also to be met by giving caffeine, which caused increased circulation, deficient quality being made up by increased quantity.

Dr. CAMPBELL, in reply, said the question of whether delusions were common was dependent upon the nature of delusions. He thought that many persons of late had suffered from political delusions. The influence of coffee, he thought, was a striking confirmation of Dr. Haig's views on the question of morning depression, that it was due to excess of uric acid in alkaline blood during the "alkaline tide." Caffein undoubtedly decreased the alkalinity of the blood. He considered that Dr. Haig's explanation was correct in many cases of morning depression, but it did not by any means explain all.

Dr. MACPHERSON read a paper entitled "Remarks upon the Influence of Intestinal Disinfection in some forms of Insanity." After some preliminary remarks as to the harm that is often done by narcotics in acute cases of insanity he stated that he had found brisk purges often of great value, especially in warding off recurrent attacks. The visceral symptoms in melancholia were next alluded to, and these had suggested to him the means described for their removal. He began upon a suitable case by washing out the stomach, the administration of calomel at night, followed by a laxative in the morning, and then regular doses of some antiseptic. He had tried naphthalin and  $\beta$ -naphthol, and found the former the better. Nitrogenous diet was restricted and peptonised gruel administered. The lecturer had found prolonged treatment essential to success, and then quoted in some detail four cases, in all of which decided improvement followed the treatment described, which he thought could be only ascribed to this treatment. Thirty other cases were also summarised. In no case was the general health interfered with; in most cases the body weight increased steadily—in no case did it fall. Sleep was very markedly improved, and this improvement was maintained without increasing doses of the drug, and was never followed by increased restlessness; in no case was there any change in the nature of the mental symptoms, and it did not shorten the period of illness, but it modified the illness materially, lessened the motor irritability and the tendency to suicide, and generally ameliorated the symptoms. Dr. Macpherson considered the drug safe, for though it failed in some cases it, as a rule, promoted nutrition and induced a normal sleep while the psychical disorder was not affected.

Dr. GOODALL thought the influence of toxines was one of increasing interest. He considered that the naphthaline would hardly injure the micro-organisms if it reached them, but he doubted whether it ever did so. He stated that the French observers had shown the difficulty of destroying saprophytes of the intestinal tract with reagents more powerful than the naphthaline in the doses used.

Dr. JOHNSON-LAVIS related a case in which he had advised intestinal disinfection after general treatment had failed. Calomel was regularly administered with marked success. He also quoted another case in which obstinate constipation, associated with chronic mental derangement was relieved by the injection of mentholised oil.

Dr. ROBERTSON agreed with the remarks of Dr. Goodall as to the importance of ptomaines in insanity. He stated that it was not necessary to destroy the germs, but only to limit their functional activity. At Morningside they had used  $\beta$ -naphthol with advantage and he had seen it successfully employed by Dr. Voisin in Paris.

Dr. RAYNER thought the treatment was likely to be of great value.

Dr. URQUIHART said that twenty years ago he had tried hyposulphite of soda for a similar purpose, but it had not been satisfactory. He suggested the use of eucalyptus.

Dr. MACPHERSON replied. He thought that Dr. Goodall was incorrect when he alluded to the failure of naphthaline to disinfect the intestinal tract. It had been shown by competent authorities that the combined sulphates vanished from the urine after administration of repeated doses of naphthaline; that, moreover, in such cases the fæces were entirely devoid of smell.

Dr. FRANCIS WARNER enumerated the chief points of a report of the committee appointed to investigate the physical and mental condition of children in schools. The results given were obtained from the examination of 50,000 children. Some of the more notable of the conclusions were as follows: As regards nationality it was found that the Irish children presented a proportionately greater number of developmental defects, their nutrition was poorer, and the number of dull children was greater and they had a greater tendency to nervous disturbance; whilst the Jewish children were decidedly superior to the English in each of the above respects. As regards the social class, it was found that the poorer classes presented a superiority to the upper in nearly every respect, and that in comparing children within public institutions to those in Board schools it was found that though the former were, on the whole, better nourished, in other respects they were decidedly inferior to the latter.

Dr. RAYNER read Dr. Frank M. Pope's paper, entitled a note on the Establishment by the Leicester School Board of a special Class for Feeble-minded Children, in which interesting details of the formation and management of this class were given.

Mr. CLARK, President of the Nottingham School Board, alluded to the large number of children of the upper classes who presented physical defects, and said that he considered that this was due to these children escaping, through social advantage, the struggle for existence. He thought that the improved morality of Jewish parents and the care which their religion demanded as to food, was largely the cause of their superiority over English children.

Dr. SHUTTLEWORTH congratulated the Association upon the work done by its committee, and hoped that the committee would be encouraged to accumulate more information, especially in the north of England.

Dr. RAYNER moved and Dr. LINDSAY seconded a resolution to the effect that the Council be invited to publish Dr. Warner's reports.

#### PATHOLOGY.

Dr. ADAMI (Cambridge) contributed a paper upon the Variability of the Bacteria. He pointed out that while it was generally held that the species of bacteria are definitely fixed, possessing properties that are constant, year by year more investigators are recording facts not in harmony with this view. The subject is one of such great importance that he had repeated a large number of the observations made by Schottelius, Laurent, Gessard, Charrin, Wasserzug, and others upon the variability of chromogenic bacteria &c. and had determined their correctness. He demonstrated variations occurring in the bacillus pyocyaneus, *B. ruber* (Kiel), *B. ruber* (Plymouth), *microbacillus prodigiosus*, *M. indicus*, *sarcina erythromyxa* and *torula rubra*, and showed that the amount of modification impressed upon the microbe and the durability of the same depend upon the extent to which the media of growth, temperature &c. are modified. A comparatively slight alteration of environment, if continued over several generations (or more truly cell multiplications), or a powerful stimulus applied for but a short time to one generation, may bring about the production of a race which for months—that is to say, countless generations—retains

the acquired characters and would seem to be permanent so long as it is propagated upon ordinary bacteriological media with ordinary precautions. Dr. Adami pointed out that while this was true it could scarcely be said that a new species had been developed in that a further alteration of environment might bring about reversion to the type. While the ordinary media of the bacteriologist might suffice for the growth and preservation of characteristics of both race and type, and while on these the race might show no tendency to reversion, an alteration of the media &c. in the direction of procuring optimum conditions of growth tends towards such reversion. Evidently therefore there must be not a little latitude in our conception of species among the bacteria; we must be prepared to discover considerable variations in the properties of any one species. The author then proceeded to show how these principles may throw light upon certain difficulties in connexion with pathogenic bacteria. He pointed out that, in addition to what we know as to the production of artificial races of pathogenic microbes, we possess a very fair body of evidence as to the existence of natural races of several species, and he considered that Cunningham's remarkable observations upon the various spirilla showing slight differences of mode of growth to be obtained from cases of cholera in Calcutta, Babes' and Cassedebat's pseudo-typhoid bacilli, Loeffler's pseudo-diphtherial bacilli &c., are all capable of explanation on the assumption that here we are dealing not with distinct species, but with races or modifications due to change of environment. He would, in part, explain the differences in the symptomatology of successive epidemics of one disease by differences in the pathogenic properties of the specific microbe, and in such diseases as diphtheria and typhoid fever would frequently see differences in the pathogenicity of the microbes gained from successive cases.

Dr. VAUGHAN HARLEY, Grocers' research scholar, read a paper on the Pathogenesis of Pancreatic Diabetes. This was another of the new school of chemical pathological papers in which the theory of the pathogenesis of the disease was not only supported by chemical data, but by clinical evidence, as well as by experimental pathological results, showing that whenever the pancreatic functions are totally destroyed a fatal form of diabetes is the result. The disease was shown by tables to be most common in the human subject in persons below the age of thirty. It was likewise shown that as the human body uses up every day in the performance of its normal functions from three to four pounds of sugar, and in the fatal form of the disease rarely more than one-eighth part of this amount is lost to the system by the urine, it cannot possibly be the sugar loss that kills, but some entirely different factor. As regards the cause of the disease, Dr. Vaughan Harley gave a variety of different kinds of clinical and experimental data, which he considered justified him in saying that the presence of sugar in the urine in cases of pancreatic diabetes most probably arose from a deficiency in the blood of normally present pancreatic glycolytic ferments to split up and prepare the sugar for the purposes of tissue nutrition; while the nerve prostration and great muscular weakness which are invariably associated with all cases of pancreatic diabetes, whether occurring as the result of disease in man or as the effects of operative procedures in animals, Dr. Vaughan Harley regards as mainly due to the retention in the organism of certain excrementitious substances, which, forming toxic ptomaines, act as ordinary poisonous materials do, and so interfere with normal tissue nutrition as to give rise to great functional disturbances and even end in death.

Dr. VAUGHAN HARLEY also read a paper on the Pathology of Obstructive Jaundice. In this communication, which embodied the results derived from a long series of chemical, pathological and experimental biological researches on the antagonistic effects, from a jaundice point of view, of ligaturing both the thoracic and common bile-ducts in animals, the author said the following justifiable conclusions might be drawn: 1. That, contrary to the accepted pathological doctrine, the bile which is eliminated by the urine and deposited in the skin and other tissues in cases of obstructive jaundice does not find access into the general circulation of the blood-capillaries at all. 2. In cases of obstructive jaundice it is the lymphatic system of vessels alone which absorbs biliary matters, and it is wholly and solely through the instrumentality of the thoracic duct that the bile finds its way into the bloodvessels. 3. After the thoracic duct has been for some time ligatured an adventitious supplementary chyle duct forms by the coalescence

of either newly developed or pre-existing collateral lymphatics from a point of the thoracic duct below the seat of ligature, through which its chyle and lymph are transmitted into the right innominate veins, and thus perform vicariously the transporting functions of the thoracic duct. 4. These facts, taken collectively, account, first, for the absence of bile acid and bile pigment from the urine in cases of obstructive jaundice, when the thoracic duct is ligatured. Secondly, for the reappearance of both the bile acid and the bile pigment, in spite of the closure of the thoracic duct, in the cases where dogs lived sufficiently long for the lymphatic anastomotic communication between the duct and general circulation to develop. Thirdly, for the animals thriving so well after both bile and thoracic ducts had been ligatured, as well as conclusively showing that, as the blood capillaries had during the time these changes occurred been totally uninterfered with, they cannot be the agents of the absorption of the pent-up bile either from the hepatic bile-ducts or from the biliary appendages; while, on the other hand, they equally conclusively show that the absorption of bile is entirely dependent on the lymphatic system of vessels. 5. As bile is freely eliminated by the blood capillaries, though it is not absorbed by them, this proves that the endothelium of the blood capillaries has only the power of permitting bile to pass through it in one direction. 6. That after the common bile-duct is obstructed the constituents of the pent-up bile do not pass out of the bile tubes and gall-bladder, to be absorbed by the lymphatics, in the same relative ratio; but, on the contrary, the mucin and cholesterin remain behind and become far more concentrated than either the lecithin, fat, soap, or taurocholate of soda. And this fact probably explains why cholesterin gall-stones are so much more commonly met with in the human subject than any of the other varieties. 7. That from the hepatic bile capillaries branch out fine bile canaliculi among the liver cells, some of which are seen to enter and terminate in the interior of individual hepatic cells in blind extremities. 8. As the dogs experimented upon not only lived, but gained in weight, after bile was prevented finding access into their intestines, I am led to the opinion that under judicious feeding the presence of bile in the intestines is neither necessary to the digestion nor assimilation of certain alimentary matters, and consequently not indispensable to life. 9. That ligaturing of the thoracic duct in dogs not only prevents obstructive jaundice occurring after ligature of the common bile-duct, but that it actually checks the signs and symptoms of jaundice after they have appeared.

#### *Researches in Cancer.*

Dr. H. SNOW read a paper on Cancer. In further illustration of his discovery that mammary carcinoma insidiously infects the marrow of the bones, Dr. Snow exhibited a sternum and part of the humerus from a patient with that disease. He pointed out the opaque-white colour of the infected marrow and the decalcification of the bony structures. The development of "the sternal symptom" (a slowly progressive prominence of that bone between the second costo-sternal articulations) by lymphatic infection of an adherent thymus was referred to. The genesis of "melanotic cancerous disease" was next considered. This arose invariably from pigment-secreting cells. Under the common title "melanotic sarcoma" two distinct varieties were confounded. The first, affecting the eyeball, sprang from connective-tissue cells and was therefore a true sarcoma, not infecting the lymph glands *per* the lymphatic vessels. The second form was an epithelial product derived from the deep columnar cells of the rete Malpighii and, as usual with such, it quickly contaminated the proximal lymph glands. All cases of melanotic cancer growth on the integument belonged to this class; they commenced in the redundant epithelium of a pigmented wart or mole. A number of crayon drawings showing the transitional development of the latter species were exhibited.

Dr. SNOW further produced two series of coloured sketches, of which the first demonstrated the characters of rodent ulcer as a malignant reproduction of hair-follicle structure, with an origin from the cells of the outer root-sheath. The second illustrated the production of globes *épidermiques*, not by endogenous cell formation as formerly taught, but by the vacuolation of cells over a large area. The epithelial cells concerned had an inherent tendency to secrete mucus; the protoplasm of one or more of their several nuclei became gradually converted into a minute vacuole or intra-cellular cyst. This was the first stage of the globe formation. These

vacuoles had lately been described by Dr. Armand Ruffer as parasitic bodies, but there was no evidence in favour of such a hypothesis. Traced further, the contents of the affected cells were seen to become more and more replaced by fluid, and eventually became blended into the laminated or imbricated corpuscles known as "*globes épidermiques*."

#### DISEASES OF CHILDREN.

##### *Ringworm.*

Dr. PHINEAS ABRAHAM read a note on Ringworm and its Treatment. He alluded to the legion of published "cures" concerning which each author had virtually cried "Eureka!" but, in spite of these certain cases of tinea tonsurans were still as intractable as ever, and mentioned a method of treatment which for some years past he had found very useful. An ointment, containing carbolic and salicylic acids (of each half a drachm to one drachm to the ounce), was rubbed in with a stiff brush twice daily, the scalp being shaved occasionally, kept closely cropped and always greasy, a cap being worn and changed daily, and the head washed with an antiseptic soft soap once a week. A number of cases had thus been cured in a comparatively short time though the majority has required several months. Additional applications, after washing, of carbolised liniment of iodine, have occasionally been made in obstinate cases or mercuric chloride or iodide (one to two grains to the ounce) has been added to the ointment. The doctor's experience had been that the more intractable instances had occurred in blonde children and in girls, and two of the most troublesome cases were in young albinos. He had met with three cases in adult women, one being very extensive and difficult to cure. He doubted whether Dr. Unna's method would be much used in hospital practice in this country on account of the time and manipulations required in applying the dressings, and alluded to the use of chrysarobin for many years by Mr. Hutchinson, Mr. Tay and others. He observed that the prophylaxis of this disagreeable disease was insufficiently attended to. Although every source of contagion could not be always guarded against, one recommendation, long ago made by Dr. Liveing, should be generally adopted—viz., that children going to the hairdresser should always take their own brushes and combs with them. The *British Medical Journal* in 1885 sounded a note of warning in reference to the extensive dissemination of ringworm by our Board schools, and Dr. Stowers and Mr. Malcolm Morris have since called attention to the subject. The matter seems of such importance that it should not be allowed to drop. It has been suggested that the school children be periodically examined by competent experts and the affected ones kept apart, but nothing has as yet been done in this direction. Children affected with tinea tonsurans still going to school are quite common at the two skin hospitals attended by the author, and it is easy to understand how the disease must thus be spread.

Dr. ALFRED EDDOWES read a paper on the Treatment of Ringworm of the Scalp. After referring to the success which Dr. Unna had obtained by his method with chrysarobin, he proceeded to describe a modification of the method which he himself now employs in out-patient practice. The essential preparations are a mild sulphur ointment and a compound chrysarobin ointment. During the first week the scalp is washed every two or three days with soft soap or soda and water and dressed daily with sulphur ointment. For as many weeks as necessary afterwards the scalp is systematically treated by the chrysarobin and the sulphur ointments according to a plan which the author described in detail. In private practice and when thorough supervision could be exercised, he recommended the plan as carried out by Dr. Unna himself; but for out-patient hospital practice he found his own modification was more suitable, though not so rapidly successful. When the ringworm occurred in schools he did not consider it at all necessary that children should lose the advantages of education and be prohibited from attending their classes because they happened to have ringworm of the scalp. In his opinion they could be treated by a simple method, which he described, until the vacation or other convenient time, and then be taken in hand more thoroughly if still uncured. He mentioned a case which illustrated the futility of attempting to treat ringworm piecemeal and showed the advantage which the taking of cultivations of fungus had over other methods as a test of the progress of the treatment. Against the general or extensive employment of mercurials he felt very strongly, and for reasons which he gave he much preferred even dirty-looking and somewhat

irritating substances to such as might contain poisons and not be so readily controlled.

Dr. P. MURRAY BRAIDWOOD read a paper on Nervous Disorders following secondarily certain Acute Infectious Diseases of Children. In this paper Dr. Braidwood considered the pathology and treatment of nervous disorders following croup (including diphtheria), influenza, measles, mumps, whooping cough, röteln, scarlatina and chicken-pox. He stated his belief that convulsive and epileptiform disorders following secondarily on acute infectious diseases in children were generally due to some accidental cause as a fright or the over-pressure of school work. Paroxysms of eclampsia infantilis closely resemble in their symptoms those of epilepsy in the adult. The convulsions may be repeated three or four times, while in the intervals the comatose condition and complete loss of consciousness and sensation may continue. The persistence of the reflex sensibility may in such circumstances easily mislead, for touching the conjunctiva produces contraction of the oricularis and sprinkling with cold water excites reflex contractions. Dr. Braidwood also considered the causes and treatment of chorea, Jacksonian epilepsy, unilateral spasms and tetanus. Massage in Dr. Braidwood's hands had yielded good results in cases of infantile paralysis, especially when he had combined it with electricity. The paper was illustrated by an interesting table of the chief nervous affections met with after the various infectious diseases.

#### THERAPEUTICS.

##### *Touting in the Medical Profession.*

Professor GAIRDNER of Glasgow said: I have asked permission to introduce some remarks into the business of this Section. Last spring it happened that I was appointed without my own concurrence in the least degree and by the unanimous voice of the committee to be the chairman of the Therapeutic Committee of the British Medical Association. I accepted the appointment under certain reserves and with certain misgivings, but these were entirely overcome when I found, some time afterwards, that the committee were at one with me in desiring that I should accept the chairmanship upon the conditions and with the reservations that I had myself made. About a year later it was discovered that the branches I had hoped to engage in the work did not, as it were, come to the rescue, and accordingly I found myself in the position of a defeated Minister. I had accepted for a particular purpose and with a particular policy in view, and I had found that the policy had broken down completely and therefore it appeared to me that the proper course was to resign the chairmanship, which I did. The resignation has been accepted with regret, but the circumstance which has made me address this Section is that I did not think all through the proceeding that the matter had been brought fairly before the public. I did not think the Sections who were written to and engaged in the matter were properly informed as to what my wishes were. I do not think the public knows, or that the members of the British Medical Association know, anything about it, and this has happened because the papers that I myself issued as indicating the policy I wished to follow have never been published. Now, mind, I am not blaming anyone. I am not wanting to raise a storm or make a personal point of this at all. I am not wishing to make any sort of mischief or disagreeableness, I am only stating as a matter of fact that I am standing here on the footing of a defeated Minister, having resigned my portfolio to the Association without its knowing why I have resigned it. It is quite true that a short circular letter from Dr. Sidney Martin was issued to each branch, but the papers in which I indicated more or less the lines which I considered it desirable to follow have never been published. Not only so, but I have received a letter from the Committee of Reference to the Journal to say that in their opinion they are not to be published. Now I am not quite willing to acquiesce in this, and all I want this Section to do is to listen to a few passages out of these papers and to say whether my views were not reasonable or, at all events, worthy of coming before the public more deliberately and more decidedly than they have done. I omit everything that is not essential, and I begin here:—

"Of the therapeutic work of the committee it may be said to begin with, that it not only constitutes, or ought to constitute, the larger part of our work, but from the very necessities of the case it must be conducted on lines differing essentially from the pharmacological work. The latter is

capable of a very direct initiative and can be carried out on a general plan by physical investigation with experiments planned in the laboratory or otherwise, so as to obtain quite definite results and subject them to all the necessary corrections; but in therapeutic inquiries, strictly so called, you must of necessity pursue quite a different method, and be contented with much less satisfactory results. You must, in the first instance, secure a field for observation. You cannot make, according to preconceived arrangements, the particulars you want in respect of diseases on which to test your medical agents. Secondly, you must have men of skill known as such to perform your experiments and more or less precisely to record the results; but the point to which I wish your attention generally directed now is that not only must you have a wide field of competent men, but you must, as the first step thereafter, cause these men individually and collectively (to whatever extent you apply the collective method) to be impressed with the idea *a priori* that the experiment you wish to be made falls within the line of their duty, and is indeed obligatory on them as dealing with sick humanity. In other words, the men whose assistance you wish to secure are physicians first and therapeutic experimentalists afterwards, and it is not competent for you to require of them to subordinate the first of these characters to the second. Hence it arises that the collective method of investigation is only in a very limited degree applicable to the kind of inquiries with which we are now concerned. You cannot, as a rule, advise in London and put into the form of a schedule an inquiry as regards a particular remedy—say, a new remedy—which will have the force of an appeal carrying the conviction that the experiment so advised is the right one to be made, as viewed from the physician's point of view; but unless this conviction is obtained your experiment cannot be made at all, or, if it is made, it will be in a very half-hearted fashion. Hence it arises that in this element of personal conviction you have a barrier at the outset to what many call 'control' experiments on a considerable scale. The men who will give you a remedy are, by a kind of natural selection, predisposed in its favour; the men who are not so predisposed will usually abstain from giving the remedy and in general will be quite right so to abstain. You must in the end take the results with this bias of what may be called 'natural selection,' or you will have no results worth speaking of at all." I omit here a paragraph which is not important. "If you have followed me thus far in this line of argument and the committee are convinced of it because all agreed with it, you will see why my mind inclines to a multiplicity of small local committees rather than to one only, guided and governed mostly from London as the absolute centre of suggestion and reference. Not but that I believe that a central therapeutic committee will have its functions greatly enhanced and its way cleared for advance by coöperating in advising and by controlling rather than initiating the great variety of research of the local committees. You have obtained the necessary starting point and, having done so, it would remain for the central committee to record the conclusions and the results which have been arrived at by the local committees. If the central committee found the results unsatisfactory they might say so, or open up the question again on other grounds, or refer to another committee, or remit the conclusions back again to the original committee. In any case the central committee would have still more important functions in becoming the medium of communication between local committees at a distance, or between these and the Association. Very important inquiries might thus be made. The local committees would be safe from the premature and biassed judgments which were now put forth upon certain drugs and which are the mere despair of therapeutics." Now, my complaint is that all this pleading never reached the Association; it not only was not published in the Journal, but it was deliberately kept back, owing to the machinery by which the work of committees is confined to the committees. The new start initiated by the Therapeutic Committee ought to have received the largest possible publicity in the Journal, to have been discussed by the Association at large at the very commencement, in which case there might have been some sort of hope of getting these local committees constituted and of their doing something. Instead of this the result has been that, except in Glasgow (where the committee has been constituted, but could hardly be induced to meet) and in Dublin (where the committee is still in existence, although it has not done anything yet) all the branches that were applied to simply

ignored or left the matter alone, and the policy has come to a state of dead failure and utter stagnation. That is attributable entirely to the Journal having either declined, or at all events having not published the basis of the remarks upon which the local committees were called for and asked for. Now, gentlemen, I am not complaining. This is not to me a matter of personal importance; in reality I am not inclined to press it, especially when I consider the severe labour and occupation which would have been imposed upon me had I continued chairman of the committee. Unless a position of that kind is filled *con amore* no good ever can come of it. I do not think, therefore, that the policy has had fair play; and I will go further, and I may say that sooner or later something of this kind will require to be done. I am perfectly satisfied that without therapeutic organisation in all our great medical centres therapeutics will go to the dogs. We are all getting more and more in therapeutics to be the victims of what in American politics is called "the machine." It is either a scientific machine, such as Dr. Sidney Martin or Dr. Lauder Brunton and all the great authorities in London who are working away at therapeutics in their libraries and laboratories—a kind of "machine" that is highly honourable; or it is a kind of machine that has found its way even into this room. It is the latter I am most afraid of. It is the "touting" machine. We see touting right and left, so much so that we are not allowed now to make up our own prescriptions. It is this apothecary in London and that physician in New York who keep urging upon us combinations of remedies used by themselves, and there is no ill to which human nature is heir that has not got its sole and universal remedy advertised all over the world. Any medical man requires simply to send his attestation that he has tried this remedy in numerous cases and always found it effective, to secure to himself that his name will get all over the world. It is that "touting machine" that is perverting all our therapeutics and lying at the root of biased judgment. How all these great advertising firms manage to "noble" the profession is a mystery to me. A good many years ago a whisky used to be advertised under the patronage of all the medical journals in this country, but it is never heard of now. But, still, it is just one instance among many of the touting plague. The evil consists in this, gentlemen, that if a firm or a man, pharmacist or doctor, chooses to take, what up to a certain point is legitimate means of advertising and puffing, if he simply chooses to put it into the proper channels for acquiring a certain amount of publicity in connexion with his name, but chiefly, and above all, to connect his name with a remedy, it is not of the slightest consequence whether the remedy is absolute and unmitigated trash—nay, whether it is dangerous or whether it is the greatest possible boon to mankind, it is not of the slightest consequence, because before it is found out he will have made his money, if he has only puffed and touted it well, before there is time to find out whether it is good, bad or indifferent. Well, before there is time to find out whether it is good, bad or indifferent, he will have made an indescribable number of guineas. That is a great snare. There is a constant golden bait held out to the man who will manage to get even a certain temporary or makeshift presentation of a particular therapeutic agent, and in consequence of that golden bait (I am not attributing anything to the honourable members of the profession, but it is applied to the advertising firms) it is of far less consequence that the remedy should be good than that it should be something that can be well touted and well advertised. I had hoped that by constituting a nucleus of therapeutic inquiry in London and by attaching to this nucleus a number of largely independent and self-regulating centres of inquiry and investigation in the provinces, so that local errors might be effectually controlled, I had hoped that we might form a kind of barrier, a protection against the constant invasion of bad, useless and worthless things, and, on the other hand, advance the interests of true therapeutic science.

#### Discussion on "Dyspnœa" and its Treatment by Drugs.

Professor GAIRDNER, in introducing the subject, said an objection to a discussion on this matter was that the term did not refer to an individual and simple fact. It was not even the name of a disease. A second objection would have been that the treatment by drugs is not the whole treatment. As the therapeutics of one form must be distinguished from that of another kind he would endeavour rather to indicate the line of treatment by drugs than to indicate any particular drug as being of any more importance than another. The

great physicians recognised three types of dyspnœa which were put in brief form by Celsus, thus: When the difficulty of breathing is moderate and not suffocating it is called "dyspnœa"; when it is more vehement, so that the breathing is suffocating, it constitutes apnœa; and when the breathing can only take place in the erect position it is termed "orthopnœa." All these words still remain with us. Orthopnœa is obviously something which differs in kind from mere dyspnœa—no doubt very often associated with it, but still containing in its differences something that was worthy of investigation. Apnœa in the last century was the general term for all kinds of dyspnœa. It is now limited to what is called "spasmodic asthma," and thus has obtained a somewhat different sense from that which was given to it originally. At all events it may be said that it is vain to discuss the treatment of dyspnœa by drugs without some kind of preliminary definition, however imperfect, to show you in what particulars cases of dyspnœa differ *inter se*. Dyspnœa, however arising, may be manifested in three distinct ways:—Firstly, by the presence of a peculiar sensation—*le besoin de respirer*; secondly, by a chemical change in the blood corpuscles, which leads to cyanosis; thirdly, by decreased activity of the respiratory reflexes and the respiratory movements. Not infrequently all these groups of phenomena coexist, though not necessarily in equal proportion. In some patients cyanosis is not apparent, while in others, as in cases of congenital malformation of the heart, cyanosis is the leading phenomena. The *rationalis* of these discrepancies is not always clear, but the following considerations may help towards its clearing up, especially in a practical sense. The minimum degree of dyspnœa which can be called pathological is what is termed "shortness of breath." In some it would appear that either from the organisation in which the excess breathing power is always low, or from an undue sensitiveness of the respiratory reflexes, the least exertion brings about a sensation of dyspnœa and with it an increased shortness of breath. The converse of this is that in other cases very serious invasions of the respiratory mechanism are comparatively little affected by breathlessness. For example, I have seen a man with the pleura so full on one side that he had been tapped several times, but he had never the slightest sensation of dyspnœa; and, to mark that more emphatically, I had counted his respiration at sixteen per minute. The sensation of dyspnœa, the cyanosis with increased efforts of breathing, are facts or manifestations which may lead to different and sometimes separate indications for treatment. Further, dyspnœa itself, being a mere group of symptoms and not a disease, the removal or mitigation of the cause is often the only real key for the effective treatment. Dyspnœa may be purely of hæmatic origin, as in anæmia, in which the blood corpuscles or oxygen carriers are both deficient, and the tissues consequently are not properly fed with oxygen. In this variety there is no cyanosis and even little of the sensation of dyspnœa. So far as my observation goes there is never orthopnœa. The patient is perfectly contented, sitting or recumbent. The respiration is as often slow as rapid and the circulation also may be languid. In this case the therapeutic indication is manifestly to restore the hæmoglobin to the corpuscles and to increase the number of these. Iron, arsenic, regulated exercise and all the remedies for anæmia are also the remedies for dyspnœa, which is a consequence of the anæmia. Failing this, inhalation of oxygen gas may be employed to bring about, *pro tempore*, the just balance between the blood and the tissues. None of the ordinary cardiac drugs can be expected to give relief. Again, dyspnœa may be due to pulmonary causes. In the first instance it may be exclusively pulmonary, and detection of the nature of the causes will, more than anything else, dominate the treatment. The typical cause here is bronchitis with emphysema. In these cases cyanosis is present and may be even extreme during an exacerbation. There may be also found a distinctly paroxysmal element, which, however we account for it physiologically, is designated "spasmodic asthma." The breathing is not so much accelerated as it is laborious, and the whole disturbed mechanism of the respiratory act shows that a patient is under the mechanical or vital necessity of making every single respiration as effective as possible by inspiring to the full extent of his vital capacity. Inhalation of oxygen gas might be suggested as a palliative, but it can only go a short way. It is very good as a temporary expedient, and I have on various occasions recommended it with advantage; but the one great therapeutic indication is to remove as far as possible the obstruction to the air

which exists in the tubes or air cells. Hence the general recognition of expectorants. Now, many people use the phrase without clearly knowing what is an expectorant. I hold that an expectorant is a remedy that acts upon what I call the scavenger muscles of the air tubes. I say that the bronchial ramifications below the cartilages are under the domination to a great extent of the muscles that line them, and that these muscles are engaged, both in health and in disease, in the perpetual process of scavenger work—clearing out, not only the mucus, but the dust and offensive matter which we are inhaling. I have endeavoured to convince myself that this is a necessary function, and, if so, there is some apparatus for its performance, and that I believe to be the muscles that line the bronchial tubes. An expectorant, therefore, is a remedy that acts upon, quickens, regulates and renders normal that which was abnormal—this scavenger function is that of the bronchial tubes. Dr. Benjamin Ward Richardson has been the first to use the term "pneumoparesis," and he applies it exclusively to the vascular system of the lungs—paralysis of the small vessels. What I wish to state here is that if I had adopted the term I should have applied it to the paresis of these scavenger muscles, and I believe that the large part of the bad effects that lead to dyspnoea is either caused or aggravated by the accidental failure on the part of these clearing muscular agents to do their duty. The science of therapeutics consists in using such remedies or drugs as act upon these muscles, quicken their expulsive methods and clear a free passage to the air. The remedies are the normal constituents of an expectorant mixture. There is quite a distinct group of causes of dyspnoea of pulmonary origin, the typical instance of which is what is absurdly called "acute croupous pneumonia." Here the obstruction is in the air vesicles, and accordingly no strained efforts of the muscles of respiration can be of any avail except in supplying those parts of the lung which are not affected. A patient with bronchitis almost always has orthopnoea; he sits up, makes great efforts, inspires to the top of his bent, but the respiration is not always quickened in proportion; but the patient with pneumonia, whether in one, two, or three lobes of the lung—that is, with pneumonia and nothing else—lies flat on his back. There is not the slightest orthopnoea; he may be more cyanotic than the other man, but he lies upon his back and breathes rapidly—50, 60, and 70 in the minute. The respiration reflexes act in the direction in which they are wanted. Expectorants here are of comparatively little use except as keeping clear the avenues of such parts of the lung as are capable of admitting air. The treatment is the treatment of pneumonia, and in this treatment opium is notoriously a drug which requires to be used with great caution. Opium no doubt acts by paralysing the scavenger muscles. Why did opium check expectation? It did not check the secretion of the skin. It checked lung secretion by paralysing the action of these scavenger muscles.

The third group includes the cases in which the initial lesion is not essentially of the lungs, or at least is not within the air passages and air cells, but which lies outside of the pulmonary apparatus altogether. It included cardiac dyspnoea, pleural and peripheral effusions, dropsical swellings, asthmatic dyspnoea &c. In this third group the working point in therapeutics is and must be in favour of the removal of the cause, whether fluid or otherwise; in cases of cardiac origin strengthen the heart by cardiac tonics to overcome the difficulty of breathing. With respect to the removal of obstructing matters which cannot be dealt with through expectorants, remember always one of these true sayings: "In morbus pulmonum ad vias urinae ducendum: in disease of the lungs act upon the kidneys"; and if time is allowed by the urgency of the symptoms—the well-known and recognised diuretics are available here, and even the so-called cardiac tonics are most effective in producing diuresis. I have been accustomed to say in administering these tonics—digitalis, strophanthus and so on—"Look well to the kidney secretion; take a note of the quantity of urine before you begin to use the drug and see whether in two, three, or five days it increases—doubles, triples or quadruples itself. If so, the action of the remedy is safe and satisfactory; if not, the opposite is the case. I would here interpolate that cream of tartar—an old friend of mine—which was long before my day championed by Cullen, is one of the best and safest diuretics. In jaborandi or pilocarpin we have a remedy of most unquestionable power, of efficient and extremely rapid action, which is ever ready to hand and requires to be mentioned only with a caveat, because in some cases of cardiac dyspnoea it may be open to

abuse and danger. Finally, there is venesection, a disused and much abused remedy, but which is still applicable to those cases in a higher degree than any remedy I know; but I dare not open up the question.

Professor LEECH, continuing the discussion, divided the cases of dyspnoea into two groups—those which are chiefly connected with the respiratory apparatus and those of cardiac origin; a third might be added—those connected with hæmatic conditions, either from alterations in the blood or from poisons. The remedies for these cases are widely different. He pointed out the value of the nitrites in lung cases with dry sounds. With a suitable preparation, for instance, nitro-glycerine, he could confidently predict relief. He described the difference between nitrite of amyl and other nitrites. Nitrite of amyl was briefer in its action, consequently not so useful in these cases. In cases of turgidity and moist sounds no relief could be afforded by those drugs. The remedies in such cases were expectorants, such as antimony or lobelia. Regarding the use of chloral or opium he agreed with Dr. Gairdner. The dangers were great in cases of dry rhonchi, and still greater when the sounds were moist. If chloral, however, were given the heart should be carefully watched. He had found ammonia to be of great use in relieving very markedly the craving for air. He also had tried the fumes of various-makers. These, on being analysed, were found to contain either nitrites, pyridine or mydriatics. He handed in a table showing this.

Dr. HANDFORD referred to one form of dyspnoea which was of a narcotic origin and closely allied to gout. It depended upon digestive disturbances. That was the dyspnoea which occurred in attacks of megrim.

Dr. HAYWARD remarked that in his earlier days he had been rather frightened with the results of pilocarpine injections, and asked particulars for its use in private practice.

Professor OLIVER said he had observed many cases of pleurisy with effusion where there had been absolutely no dyspnoea, and illustrated this by one case from which twenty ounces of fluid had been removed.

Dr. WILBERFORCE SMITH suggested that "succus belladonnae" might be used with advantage instead of the fumes.

Dr. PEARCE referred to the use of aconite in the spasmodic form of asthma.

Dr. NORMAN KERR stated that he was a sufferer from dyspnoea and had tried all the drugs to be found in the Pharmacopœia, ranging from whisky to belladonna and aconite. He had generally found the first dose of these drugs to be efficient, but their action was not kept up. He had only taken three medicinal doses of whisky in his life.

Dr. WALKER (Pollokshaws) referred to dyspnoea due to overloaded stomach and bowels, which he had seen cured by the use of strong purgatives. He had also used iodide of potassium combined with belladonna and digitalis with good results. He thought the mistake Dr. Kerr had made with the whisky was that he had not taken enough of it. He recommended him in case of another attack to try it in larger doses.

Dr. SINCLAIR COGHILL divided the remedies into those which were directed to relieve pulmonary asthma and those which were directed to relieve cardiac dyspnoea and reflex dyspnoea. It was a very important thing for the practitioner to have a variety of remedies and if possible to use them with reference to the causes of dyspnoea and condition of the patient. Iodide of potassium was frequently very efficacious, and the late Principal Barclay of Glasgow, who suffered for many years from this affection, was cured by it. Another remedy which he mentioned as being largely used at the Hospital for Consumption at Ventnor was the tincture of the Virginian prune and the compound spirits of chloroform.

Professor GAIRDNER briefly replied and the discussion terminated.

#### LARYNGOLOGY.

In this Section Dr. MACINTYRE gave an interesting demonstration of Micro-organisms in Throat Disorders. He began by alluding to the term "catarrh" itself, and pointed out that for the most part it was merely a manifestation of something else which caused it. He drew some pictures of typical cases which should be classified under the heading of catarrh, and then passed on to the consideration of the causes of these. He began by referring to the etiology, and made reference to the ordinary conditions which are described in the text-books

as producing or modifying catarrh. He wished to pay special attention, however, to the question of bacteriology, which was influencing so much every branch of medicine and surgery. He pointed out how catarrh may be produced from bodies applied to the external substance of the membrane and from constitutional poisons injected at a distance, and led up to the conclusion that certain agents applied from without and other agents brought from within might result in the production of signs in the throat and nose which, when grouped together, give rise to the term "catarrh." Under favourable circumstances the causes were ultimately cast out and local changes disappeared, but too often secondary changes were set up of a detrimental nature. The etiology was demonstrated by specimens and drawings of all the known organisms which produce a morbid influence and are found in the nose and throat. The important point which he wished to advance was that inflammation and even purulent inflammation might result from the absorption of inorganic materials, of which the best example was afforded by sterilised chemical substances which were the products of micro-organisms themselves. Local inoculations of these products might cause irritation or even death at the part, but they also set up inflammation in the vicinity. Older surgeons got rid of a foreign body and expected the secondary inflammation to disappear. But they knew nothing of microbial invasion, and hence catarrh itself was too often treated instead of the cause. This important point had a great bearing upon the treatment. If catarrh were really a manifestation of disease, and to be interpreted as a method of nature of getting rid of a difficulty, the practitioner's whole efforts ought to be to relieve the cause upon which catarrh depended. Where this could not be done every aid should be given to the *vis medicatrix nature*, and there was no use hampering it by applying sprays, gargles or other agents in trying to remove organised structures. The etiology was further referred to with special reference to the various diatheses. Some important points bearing upon anatomy and physiology were noted and the pathology carefully gone into. Special attention was paid to the treatment of secondary results which must naturally follow obstruction to the breathing.

## EXHIBITS.

(Continued from p. 278.)

WE resume our notice of the Sanitary Exhibition held at Nottingham last week. At Stall 14 Mr. John Barker of London exhibits an operating table, bed-rests, and orthopedic contrivances. Stall 15: Messrs. J. Tylor and Sons of Newgate-street, London, have a very large and interesting display of closets, Ariston's lavatories and everything appertaining to this department of sanitary science. Stall 16: Mr. G. Jennings of Lambeth, London, exhibits his improved sanitary appliances. Stall 17: Mr. John Greenall, Portland-street, Manchester, shows a large variety of steam washers and laundry specialities. Stall 18: Mr. F. Cook of Nottingham, sanitary engineer, shows a large variety of sanitary apparatus of various kinds, including Messrs. Farmiloes, Twyford, Woodhouse Osborne Company's specialities. Stall 19: Messrs. Solory and Son, sanitary engineers, Nottingham, have a stall mainly devoted to matters of domestic hygiene, containing Messrs. Bostel's, Farmiloes', Walshe's and others' specialities. Stall 20: Messrs. Quirk and Sharpe of Liverpool show an excellent patent joint which affords one solution to the difficulty of joins for earthenware and metallic drain-pipes. Stall 21: Mr. Joseph Shaw of Huddersfield shows a health water-pipe which consists of a wrought-iron tube lined with block tin. Dr. T. Maccall of Southport exhibits on Stall 22 a portable Turkish bath for use in private houses, hotels, hospitals &c. It is a complete chamber, heated and ventilated, giving a thorough Turkish bath on a small scale. A very neat and pretty display of cycles is made by Messrs. F. Pearson and Son of 12, Angel-row, Nottingham. Mrs. Philip Monkhouse, London, S.W., occupies Stand 24 with her patent Excelsior Bed Lift, as supplied to the Admiralty and leading hospitals. On Stall 25 Messrs. F. C. Calvert and Co. of Manchester are showing quantities of carbolic acid for medicinal, surgical, and disinfectant purposes, preparations from carbolic acid, carbolic soap and carbolic dental preparations. A speciality is the carbolic vaporiser for purification of the air in sick rooms, removal of mosquitoes and other insects, and for general use where an aerial disinfecting and purifying agent is required. Mr. Henry Ellison, jun., of

Cleckhenton, Yorkshire, shows on Stall 26 a number of carboline and carbolic disinfecting fluids and powders. Messrs. Thomas Danks and Co., Limited, of Thurland-street, Nottingham, have a large stand (No. 27), on which is a very good display of lavatories of the most approved kind; also a large and varied assortment of ventilators of the newest designs, including Boyle's, Sherringham's, Tobin's &c., a Moule's patent earth closet, designed for houses where a water-supply cannot be obtained; a collection of Cheavin's gold medal filters, the filtering parts of which can be easily removed for cleansing. The Wilson drawing and dining room gas-stoves in all varieties are also on view. In addition Messrs. Danks and Co. exhibit an assortment of the latest domestic appliances, comprising vegetable slicers, revolving graters, boot cleaners, a drip-tin with revolving grid, patent dustbins &c. Altogether the stand makes a most interesting display. Mr. J. Jones of Chelsea shows automatic seal air-tight manhole covers, bag, drain and pipe stoppers, screw expanding drain-plugs, inlet ventilators &c., on stall 28; and Messrs. John Watts and Co. of Bristol exhibit a patent asphyxiator for applying the smoke test to drains for disinfecting purposes and for the destruction of vermin in holes, on Stall 29. The Sanitas Company, Limited, of Bethnal Green, London, show various disinfecting fluids, oils, fumigators, &c., on Stall 30; and No. 31 is occupied by Messrs. Billington Brothers of Liverpool with institution bedsteads, which can be adjusted in various ways. The Longford Wire, Iron and Steel Company, Limited, of Warrington, display some strong wire mattresses on Stall 32. A very nice assortment of earthenware and enamelled goods for hospital use is exhibited by Mr. Fred Henry, of Derby-road, Nottingham, on Stall 33. Stall 34 is occupied by the Leather Rubber Boot Company of Leeds, who display the excellent leather and rubber boots and shoes of Scafe's patent; whilst Stall 35 is tenanted by Messrs. I. and R. Morley of Nottingham, Mr. Darby being in charge. The firm make a very fine exhibition of natural wool pure undyed goods. There are a few white merino articles of pure wool and copper, and there are also silk goods. In some of the cotton stockings the sanitary black dye has been used; this is harmless, clean and fast, so that it does not soil underlinen. The Ceres Automatic letter and card files are seen on Stall 36. The file consists of a box or cabinet of drawers made to any size, and the letters are arranged standing up at a convenient slope against a sliding support, which moves easily by pressure applied at any distance from it, but jams automatically by the slight weight of letters against it. There are movable alphabetical division boards, and the letters are dropped in between them in dictionary order, the letter of the latest date being in front. Mr. J. A. Robertson, jun., of Peterborough, shows a doctor's bicycle on Stall 37 and on Stall 38 Surgeon-Lieutenant-Colonel W. H. MacNamara of Aldershot exhibits a model of a water-closet. The object is to cut off pan and fittings from the interior of the house when the closet is not in use, so that gases escaping from the pan or fittings might escape outside. The Trent Gas Engine Company, Limited, of New Basford, have one of their One Trent gas engines at work on Stall 38. Stall 39 is occupied by Mr. L. Worthington of Westminster, with prize drawings and detailed specification of model lodging-houses for the London County Council. On Stall 40 Messrs. Merryweather and Sons, Limited, of London, exhibit a new patent hydraulic sewer flusher, "microbolisers," and pumps. On Stall 41 Messrs. J. Stone and Co., Deptford, have a glass model of their patent field automatic syphon cistern. On Stall 42 the Nottingham Corporation exhibit water meters, pipes, joints and other fittings; and on Stall 43 the Wales Carriage Engineering Company, Limited, of Sheffield, display an automatic flush tank and hough closet, a high-pressure side valve &c. An account of the museum exhibits is reserved for our next issue.

## BRITISH MEDICAL TEMPERANCE ASSOCIATION.—

The annual prizes of £10 and £5 offered to medical students in their third year by the British Medical Temperance Association for a written examination on Alcohol have this year been awarded as follows:—First prize: Mr. D. F. Harris, B.Sc. Lond., of Glasgow University. Second prize: Miss E. J. Moffatt, London School of Medicine for Women. Honourable mentions to Messrs. S. J. G. Carré, F. Chown, W. A. MacKay and M. A. Saltmarsh. The examiners were Professor McKendrick, Dr. Moir, Dr. Morton, Dr. Richardson, Professor Simpson and Professor Sinclair.

ARMY MEDICAL DEPARTMENT REPORT  
FOR THE YEAR 1890;  
WITH APPENDIX. VOL. XXXII., 1892.

## [SECOND NOTICE.]

A TABLE is given on p. 22 of the report showing the admissions, deaths, number of men invalided and number constantly sick from each arm of the service in the United Kingdom, with the ratios per 1000 of strength, and, by way of comparison, the corresponding ratios for the previous ten years. From this we gather that the highest admission ratio was in the cavalry, 912.9, the next being 905.8 in the Foot Guards, which stood highest in this respect for the average of the previous ten years. The Royal Engineers appear to have the lowest admission, as well as a low ratio of constantly sick rate. With regard to constant inefficiency through sickness the Foot Guards had the highest ratio, 64.44 per 1000 for 1890, and the average of the previous ten years 58.83 per 1000. As regards the mortality rate, the highest, 6.73, was in the regimental depôts in 1890, as well as on the average of ten years; the lowest ratio was 4.10 in the Household Cavalry, and 4.81 in the Infantry. The Royal Artillery death-rate, 6.45, was the next highest to that of the regimental depôts in 1890. Invaliding was highest in the Household Cavalry and next in the Foot Guards in the same year; and in that preceding and in the decennial average the highest ratios were in the same arms of the service, but their relative position to each other was reversed. Of the battalions of Foot Guards, the 1st Battalion Coldstream Guards, stationed in London, gave the highest admission and constantly sick rates, whilst the 2nd Battalion, stationed four months in London and eight at Windsor, gave the lowest ratios. The highest annual mortality rate, 14.34 per 1000, was in the 2nd Battalion Grenadier Guards; in the 2nd Battalion Coldstream Guards there was no mortality. Invaliding rates ranged from 34.43 per 1000 in the 1st Battalion Grenadier Guards to 15.03 in the 2nd Battalion Coldstream Guards.

The average strength of officers in the United Kingdom, calculated from the annual returns for 1890, was 3963, among whom there were 1553 attacks of illness and 23 deaths. The rate of sickness was 391.9, and that of mortality 5.80 per 1000, a slight increase on the corresponding rates of the previous year.

In an average strength of 10,591 women there were 4349 cases of sickness, exclusive of ordinary parturition, and 61 deaths in 1890, the rate of mortality being 5.76 per 1000. The average strength of the children was 21,371 and there were 10,914 cases of sickness and 493 deaths, being in the ratios of 510.7 and 23.07 per 1000.

As regards the section of the report devoted to recruiting we may remark that nearly half the total number of recruits passed fit for the service were between eighteen and nineteen years of ages; that nearly 14,000 were between 5 ft. 4 in. and 5 ft. 6 in. in height and only 1143 between 5 ft. 10 in. and 6 ft. upwards, out of a total of 33,362 recruits approved; excluding boys enlisted under seventeen years of age, the average age of recruits finally approved during the year 1890 was 19.1 years, the average weight 120 lb. and the average chest measurement 33.5 in. In the two latter respects the corresponding measurements were slightly less than those of the previous year.

As regards the army abroad we must be content to take a few stations as samples and by way of illustration. The health of the troops serving in the Mediterranean during 1890 seems to have been satisfactory. At Gibraltar the death-rate was only 3.22 and 1 had declined by 2.45 per 1000, as compared with the preceding year; and there was also a decline in the admission, constantly sick, and mortality rates, as compared with the corresponding rates for the previous ten years. Enteric fever caused twenty-six admissions and four deaths during 1890, being in the ratio of 5.6 and 0.86 per 1000 respectively. There was, as usual, much inefficiency from a continued form of fever. Some of the cases were severe and suffered frequent relapses; the two deaths recorded under this heading did not present any obvious distinguishing characteristics of enteric fever. Rheumatic complications were frequently met with and convalescence was often very protracted. Influenza appeared in an

epidemic form in the early part of the year and caused a large amount of inefficiency. An elaborate scheme of main drainage and water-supply has been put forward for Gibraltar, which has, however, been the subject of some criticism and opposition on the part of the civil population. The sanitary services effected during the year were very numerous, particularly as regards improvements in drainage, ventilation and the concreting of the floors of barracks and huts. The station hospital having been divided and a part handed over to the navy the accommodation for the sick of the garrison has been found insufficient and a proposal for a new station hospital has been put forward. At Malta the average strength for the year was 7055, and the death-rate 9.77 per 1000. There were sixty admissions and twenty deaths from enteric fever, being in the ratios of 8.5 and 2.83 per 1000 respectively. All the cases returned as enteric fever were of a severe type, and it is probable that many of its milder forms were returned as simple continued fever which caused an admission-rate of 85.5 and a death-rate of 1.28 per 1000 respectively, and was characterised by a tendency to frequent and severe relapses and to be followed by rheumatism, sciatica and prolonged convalescence. The principal medical officer considers that on sanitary grounds no soldier under nineteen years of age should be sent from England to any Mediterranean station for duty. One third of the troops during the summer months slept in tents, as heretofore the practice, and with excellent results as regards their health. A large number of wooden huts sent out in the previous year were taken into use and highly approved of. The civil authorities have contributed towards improving the sanitary state of the towns, in which many of the barrack buildings are situated, by the construction of additional large ventilators to the main sewers and improving the ventilation of houses.

At Bermuda enteric fever was very prevalent among the troops stationed there. There were sixty-two admissions and ten deaths, being in the ratios of 40.1 and 6.47 per 1000 from that disease in 1890. The cases were distributed through the garrisons occupied, with the single exception of Ireland Island. The immunity of this place is attributed to free exposure to the wind and to its having little or no communication with the insanitary towns of the mainland. The senior medical officer considers that until the sanitation of Hamilton and St. George's are radically improved, there will be a great liability on the part of soldiers visiting these towns to contract enteric fever. With this cause of sickness and mortality removed Bermuda should be one of the healthiest of the British colonies. It is a popular winter resort with the Americans. The strength of the British troops serving in Egypt was 3209. The relative sickness in Cairo and Alexandria was as follows:—At Cairo, with an average strength of 2304, the ratio of admissions was 913.2 and of deaths 6.51; at Alexandria, with a strength of 905, the rates were for admissions 1185.6 and for deaths 26.52 per 1000 respectively. Compared with the corresponding rate of the previous year there was a decided decrease in the rates of sickness and mortality at Cairo and a marked increase in both ratios at Alexandria. Much of the sickness at the latter station was attributable to the prevalence of enteric fever in the 2nd Battalion Suffolk Regiment, a newly arrived regiment in Egypt.

## CYCLING AND VITALITY.

It was recently announced in the daily papers that a rider had, on an "ordinary bicycle," covered 413 miles in twenty-four hours. The feat seems incredible; and it would be interesting to know what the philosopher who predicted some thirty years ago that a cyclist could never travel faster on two wheels than he could on his two feet would think of this achievement. Anyway the thing has been done, and, what is more, there are many cyclists, men of experience in the art, who look upon it quite calmly, and predict boldly that good as this "record" is, it has been made to be beaten as certainly as it has beaten those which have gone before it. Where is pace in cycling to end? we exclaim. Well, that is impossible to say. We know a cyclist—a member of our own profession—who declares that if he could be protected from the impeding influence of the wind and could be put on a line of railway—properly laid for the purpose—he could, if placed behind an engine tearing away at the rate of twenty-five miles an hour, keep up with the engine for one hour at

least. At one of the meetings of the Society of Cyclists, over which Dr. B. W. Richardson presided, he gave a new reading to these feats. He saw in them the first true efforts leading to the practical accomplishment of aerial flight. These are subjects for the future. What we have now to do is to accept what is achieved, and estimate the cost at which the present rapid movements on wheels have been secured: the cost of vitality in the efforts of the rider, less the risk of accidents to which he is subjected.

In the month of May in this present year the value of despatch cycle riding was put to the test, in order to show that military messages can be carried by the relay bicycle more rapidly than by horse riding. A despatch was sent by a bicyclist from General Miles in Chicago to General Howard in New York, over a distance of 1000 miles, with the expectation that the work could be done in 100 hours. It was done in 108 hours, a success that could not have been approached by the best mounted rider on horseback. But again comes the question, At what cost? The cost to the rider is, we say at once, altogether unwarrantable, for during the twenty-four hours in which a rider is occupied in covering 400 miles his heart knows no rest from full activity, and the elastic coat of every artery in his body is in full tension. In some instances such is the tension that the man literally propels himself in what may be called blindness. His legs work automatically and his course is directed in a manner very little different. When a bicyclist was unfortunately killed from an accident caused by fast riding, a witness said, on oath, that the rider was going so fast and was so intent on the race he did not hear witness until it was too late, that is to say, until he got within two yards of a cart into which he ran, when he altered his whole position, called out "Oh!" and coming into collision received the fatal injury. In another instance, where one of the long and sleepless rides was carried out, the rider was seized with vomiting, which never ceased during the whole of the effort. He, too, lost the guiding power of his senses, and for some miles tugged on as if he were blind, tearing away, in fact, in a kind of trance, his higher nervous centres paralysed and his body retaining its life and mere animal power, held living by the respiratory centre and the heart, they also being taxed to the very extremity of danger.

When we, in these columns, tell plain and unvarnished facts of this character, we are sometimes accused of being alarmists. We care nothing for that harebrained stigma. We have our duty to perform, and it is our duty to declare, from a knowledge of the bodily powers and function, that the risk implied, even when there is escape from immediate accident, is dangerous up to the verge of insanity. We do not deny that every now and then a young man in the bloom of health and full of vital energy is able, during his short physical prime, to complete these remarkable feats and stand out for the moment the model of physical power in this one direction of it. Watching him in the plenitude of his strength, his companions will jeer at us and will ask us to tell them whether we can detect in him any demonstrable change for the worse. We are prepared to say "perhaps no," for we have not yet at our command the knowledge and means for detecting the first and minor indications of organic injury from physical strain. We admit, further, in all fairness, that a man may one or more times pass through the strain and not be so much injured as to be left bearing, necessarily, a life so shortened that the period of the shortening will admit of correct measurement. But with so candid an admission we must claim to hold with equal candour the facts that, although we may be unable to determine the infliction of injury by our present refined methods of diagnosis, we have the best and most common-sense reasons, derived from experience, for assuming that the body at any age and in the finest condition cannot be exposed to the strains to which we refer without being oppressed beyond the bounds of safety; whilst we are absolutely certain that the oppression often repeated is of necessity a serious cause of organic degeneration. On this last head experience of the clearest kind is our guide and monitor. We have watched the fate of those who, in the brief period of the history of these violent exercises of strength, have excelled and have run through their short day and generation, and we regret to record that no experience is more painful or more instructive for purposes of warning. Man is not an engine of iron and steel, but an organism of flesh and bone and blood that has to be renewed from day to day and from hour to hour, and his energy is not roughly

chemical but vital in its nature; he is constructed for other and nobler purposes than mere engine labour; and if he throws himself into mere engine work he will soon become an engine so disabled that his better self will fall into death before he has reached what in others better trained would be the prime period of vital strength and activity.

## THE AMERICAN MEDICAL ASSOCIATION.

### [FIRST NOTICE.]

THE recent meeting at Detroit was probably one of the most important and best organised which the Association has ever held. Considerably over 1000 medical men were present from all parts of the States, and not only the general meetings, where what may be called medical politics are for the most part discussed, but also the meetings of the various sections, which occupied themselves with matters of purely professional or scientific interest, were conducted with a vigour and energy which showed how intent the members were on the various matters which had to be discussed. There were in all twelve sections, each with a chairman and a secretary of its own, and although occasionally a meeting of one or more sections had to be adjourned out of consideration for the absorbing interest which surrounded a few of the general meetings the amount of work which was accomplished was by no means small.

The meeting was opened in the Detroit Opera House. The stage was beautifully decorated with flowers and palms, and the house was filled with an audience which was evidently keenly interested in all the proceedings. After Bishop Davies had offered prayer and General Alger had in a few appropriate words welcomed the Association to Detroit the President of the year, Dr. Marcy, of Boston, delivered an address, the subject being "Evolution in Medicine." This somewhat technical title scarcely conveys an adequate idea of the scope and bearing of the interesting address which was delivered. It was indeed more a description of the development of the American Medical Association and an indication in outline of the direction in which it should proceed in the future, with the view of drawing closer together the various associations and societies throughout the country and of strengthening the hands of those who are endeavouring to press on reforms in regard to medical matters. One subject was referred to in the address in which the orator evidently carried with him his entire audience—viz., the proposed establishment of a national board of health presided over by a secretary of public health who should be *ex officio* a member of the Presidential Council. Such a board would take cognisance of all that affects the public health of the community, especially of epidemic and infectious diseases, and there seemed to be a universal consensus of opinion that such a central board would, in coöperation with the State boards of health, be the means not only of enforcing sanitary regulations but also of educating the people to recognise their importance and desirability.

A most interesting and instructive address on Surgery was delivered on the second day by Dr. John B. Hamilton. His subject was "The General Principles of the Surgery of the Brain and its Envelopes," and the plan which he adopted of stating concisely the object and the result of numerous cranial operations carried out by various operators was probably the most telling way of putting his arguments for free interference on general principles with the brain and its envelopes. A glance over the cases enumerated by him is sufficient to show the enormous strides which brain surgery has made in the last few years. At the conclusion of his address he strongly advocated the principle which has been laid down by Horsley and Hayes Agnew, that all depressed fractures, slight or severe, ought to be surgically treated with the view of preventing the too frequent sequel of such accidents—viz., traumatic epilepsy. In this way alone, it was urged, will traumatic epilepsy be satisfactorily grappled with.

The address in Medicine on the third day was delivered by Dr. A. L. Gihon of the United States Navy, who discussed in an admirably suggestive way the relation of bacteria and their products to disease, dwelling especially on the views as to protection against the influence of microbes recently brought forward by Dr. Sternberg of the United States Army, and others.

Such were the addresses delivered to the Association as a whole. We reserve for a subsequent notice a short account of the work of the sections.

## PICTURES AND BUSTS IN THE ROYAL COLLEGE OF SURGEONS.

THERE has just been published a catalogue, compiled by Mr. F. G. Hallett, of the portraits and busts in the Royal College of Surgeons of England, with a short biographical notice of each. In the introduction to this catalogue Mr. Hallett writes: "A wish has been expressed on several occasions that a catalogue of the pictures and busts in the possession of the Royal College of Surgeons of England should be compiled, and although from time to time attempts have been made to supply the want, no one has hitherto been able to give the time necessary for searching the minutes and other records of the College. In publishing this catalogue it is hoped that the short biographies may lend additional interest; and although it is not intended that they should be exhaustive, an endeavour has been made to give as complete a record as possible of the appointments held by those who have assisted in creating the history of the College." There is no doubt that the catalogue has not been compiled without considerable research and that the various notices of the distinguished men represented in the College collection are accurate and carefully compiled. There is an index at the end of the catalogue which enhances its value. The catalogue may be looked upon as authoritative as regards dates and events in the lives of those mentioned in its pages. There are some thirty-one busts and thirty-seven portraits in the possession of the College, and various plaster casts of busts, engravings, miniatures, sketches &c. The portrait groups include amongst them one representing His Majesty Henry VIII. granting the Act of Union to the barbers and surgeons, the figures of which are attributed to Hans Holbein; a painting, "The Dissecting-room," by T. Rowlandson, said to represent William Hunter demonstrating to his class in the Great Windmill-street School-dissecting-room; a copy of the picture by Rembrandt, in the national gallery of the Hague, of Nicholas Tulp and his pupils; a group of the Council of the College in 1884, painted by Henry Jamyn Brooks. It will not be surprising to find that the memory of John Hunter has been more honoured than that of any other, and we find there is a life-size statue by Weekes, a portrait by Sir Joshua Reynolds, a copy of this by Muller, a miniature copy in enamel of the same picture by Bone and engravings of it by Sharpe; a medallion by Tassie, busts by Harman and Sir Francis Chantrey, a plaster cast of the above, and a pencil portrait by Sir N. D. Holland, Bart. There are busts of their Majesties George III. and George IV., by Sir Francis Chantrey; of the "Right Honourable Lord Grenville," by Thomas Phillips; and of "Dr. Georg Friedrich Louis Stromeyer," by W. Englehard; but with these exceptions we find none but those whose work has contributed to the fame of the Royal College of Surgeons, the names of the majority of whom are known throughout the world. The catalogue is well printed on excellent paper, and leaves nothing to be desired. We understand that the price of the book was fixed at half-a-crown at the recent Council meeting, so it is within the reach of all taking an interest in the College.

## INTERNATIONAL CONGRESS OF EXPERIMENTAL PSYCHOLOGY.

THREE years ago the first Congress of Experimental Psychology met in Paris. The second Congress was opened on Monday at University College, London, with Professor H. Sedgwick as President. The Vice-Presidents are Professors Bain, Baldwin, Ebbinghaus, Ferrier, Hitzig, Liégeois, Preyer, Delboëuf, Richet and Schäfer. The honorary secretaries are Mr. F. W. H. Myers and Mr. James Sully. The Congress numbers about 270 members, including distinguished representatives from Germany, France, Holland, Roumania and the United States, as well as from this country.

The feature of the first day was the inaugural address of the President. After welcoming the members of the Congress to this country, more especially those who formed a con-

necting link with the Congress of three years ago, he said that the selection of this country for the second Congress, while not in need of any defence, suggested the admission that England rather lagged behind in the matter of experimental psychology—if the term experimental were taken in the narrow but usual sense to denote investigation under artificial conditions. If, however, the term were taken in its wider sense to mean the whole science of mind, so far as it was based upon observed facts, then, looking at the long line of English psychologists from Locke and Hume down to Bain and Spencer, no one, he thought, would contest the claim of England to be regarded as the ancient home of psychology. The term "experimental" for the purposes of the Congress, was to be taken as intermediate in meaning between the stricter and more lax meanings alluded to, so that it included all investigations in which the reasoning was based upon observations methodically pursued for a special purpose, even if they were not in the strictest sense experimental. Reference was made to the connexion between physiology and psychology, and it was pointed out that the antagonism between what may be called the neurological and psychological platforms, which was so strong twenty or thirty years ago, had now to a great extent disappeared, for the crude materialism which refuses any recognition to the results of introspection and the psychology which claims a realm in which psychical processes are unaccompanied by nervous processes are equally out of date. Thus it had now become clear that the issue between materialists and psychologists related to the nature of the causal nexus which linked each successive double fact with physical and psychical antecedents and consequents. But the empirical psychologist might leave this [discussion on one side and content himself with tracing uniformities among the psychical phenomena which he studied with their physical accompaniments, without entering on the question of their causation. For this task physiology was extremely useful, and they recognised this by constituting a section in the Congress for papers mainly physiological in character. There was also a section for "Hypnotism and Cognate Subjects" and they were fortunate in having so many French hypnotists among them and especially from the Nancy school, where the work had been conducted on the broad lines which have been generally followed in Europe.

The first paper was that of Professor Bain. This dealt with the relations of introspection and psycho-physical experiments as mutual aids in psychology. In comparing the two methods it was pointed out that in the qualitative analysis of mental facts introspection must take the lead; while in quantitative analysis, or the mensuration of psychological quantities, the experiments of psycho-physics can render important service. Researches were enumerated in which the two methods concur, and it was pointed out that in all experiment any come as an aid to introspection, but cannot profitably supersede it.

Professor Grüber of Roumania read an interesting paper on Colour Hearing, explaining, however, that his subject was more extensive than the name implied, as it comprehended all cases in which the stimulus of one sense evoked images belonging to another. Reference was made to the careful observations of these phenomena by Mr. Francis Dalton, and the belief was expressed that the inquiry was still one of purely scientific interest, although the persistency of the phenomena suggested the possibility of a law which might in the future have some practical bearing.

A paper by Professor Ribot was read by Professor Richet, and subsequently one by himself entitled "L'Avenir de la Psychologie." It was pointed out that the first problem of psychology was the physiology of the brain and the imperfect character of our knowledge of this was emphasised. The difficulties of the studies were alluded to and it was pointed out that by means of comparative psychology some light might be thrown on the causes of madness and crime, and in conclusion the importance and vastness of the psychological field were alluded to.

At the meeting of the Congress on Wednesday several important papers were contributed in Section A. These were the more strictly physiological papers. They were as follows:—The Visual Centre in the Cortex of the Calcarine Fissure, by Professor Henschen; the Degree of Localisation of Movements and Correlative Sensations, by Professor Horsley; the Anatomical and Physiological Relations of the Frontal Lobes, by Professor Schäfer; and the Functional Attributes of the Cerebral Cortex, by Dr. Waller.

On the third day papers were read in Section A. by Dr.

Verriest, Dr. Mendelssohn, Professor Heymans and M. Binet, and in Section B by Professor Delbœuf, Professor Hitzig and Mr. Myers. In the afternoon Professor Baldwin discoursed on "Sensibility and Will" and reports were given of the Census of Hallucinations. To these we hope to refer more particularly in our next issue.

## THE CENTRAL LONDON DISTRICT SCHOOL.

DR. SYDNEY STEPHENSON presented to the Board of this school at their last meeting his third annual report, in which he states that the new buildings for the accommodation of children suffering from ophthalmia, sanctioned by the Board, had been completed and that they had been now occupied by such patients for two years. The greater number of admissions had come direct to the ophthalmic school from the various institutions belonging to the parish of St. Saviour's. The largest group of children, numbering no less than forty-three, were admitted on Nov. 16th, 1891. He advocates the removal of children affected with ophthalmia from the work-houses and infirmaries of London, because no proper accommodation exists for such cases and the treatment is consequently in many instances rendered nugatory. If granular lids were an affection admitting of rapid cure detention of the cases in the metropolitan infirmaries would be a matter of little moment, but the fact that the disease is very persistent meant serious interference with the proper functions of a workhouse or Poor-law infirmary. The ophthalmic school at Hanwell was built specially for its purpose two years ago, at a cost of nearly £30,000, and has accommodation for 134 boys and the same number of girls and of infants. Now out of fifteen available wards only eight were occupied, and the accommodation designed for 400 children contained only 111 ophthalmic cases. The nursing staff, which consisted originally of seven nurses in charge and fifteen assistant nurses, has been reduced to three charge and five assistant nurses. The education of the children is not neglected, one master being appointed for the boys, one mistress for the girls, and one assistant mistress devoting her mornings to the infants. The present arrangements, which have in great measure been thought out and carried into execution by Dr. Stephenson, appear to be excellent; and his report was regarded by the members of the Board as highly satisfactory.

## METROPOLITAN HOSPITAL SUNDAY FUND.

THE following annual general report of the Committee of Distribution to the Council of the Metropolitan Hospital Sunday Fund has been submitted to and adopted by the Council of the Fund:—

Your committee have the honour to recommend the payment of awards to the 173 institutions enumerated in the appendix to this report (see page 77), being one more than last year, and an increase of sixty-eight since the first awards were made in 1873.

The total amount available for distribution, after allowing for liabilities and the usual current expenses, is £40,228. Of this total £40,118 15s. is now recommended to 120 hospitals and fifty-three dispensaries.

Five per cent. of the total collected—viz., about £2000—is set apart to purchase surgical appliances, in obedience to Law XII., in monthly proportions during the ensuing year.

Your committee recommend that all payments to the Fund after Aug. 1st be carried to the credit of next year's Fund.

In compliance with an Order of the Council, and for the special use of its members, tables of statistics have been prepared as usual, showing an analysis of the number of beds in hospitals, the cost of patients both at hospitals and dispensaries, the proportionate expense of management, as well as other valuable information, and copies are sent to every member of the Council.

The number of deputations representing committees of various hospitals &c. invited to confer with your committee and to offer explanations on matters of apparently unsatis-

factory character was sixteen. Of these, seven elected to leave their awards entirely in the hands of this committee. Nine were invited to send deputations to meet your committee. Of these, one is recommended for award on its full basis, five on a reduced scale, and three are not considered to be entitled to anything.

Awards are therefore recommended to 157 institutions on their full bases, to thirteen institutions on reduced bases, and three institutions which have made applications are not recommended for any award.

DAVID EVANS, Lord Mayor, President and Treasurer.

SYDNEY H. WATERLOW, Vice-President.

JOHN D. ALLGROFT.

OWEN ROBERTS.

H. COSMO BONSOR, M.P.

W. SEDGWICK SAUNDERS, M.D.

HERMAN HOSKIER.

JAMES WHITEHEAD.

ALFRED WILLETT.

Mansion House, July 20th, 1892.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*Worcester Urban District.*—The death-rate for the city of Worcester during 1891 was 21·6 per 1000 living, the excess over the average being largely due to fatal whooping-cough; but there is also an excess of death amongst infants under one year of age. Some satisfactory method of dealing with the refuse of the city is evidently needed, for it seems to be deposited under circumstances calculated seriously to damage health. The arrangement of the report is inconvenient. It is signed by Dr. Mabyn Read on an early page; then follows an account of the census, remarks on statistics, on notification, disease occurrences, the hospital, water-supply &c.; but there is nothing to indicate their authors. We assume, however, they are written by Dr. Read, since other added matter is signed by the inspector of nuisances and by Dr. Horace Swete. Anyhow, we are glad to learn that the state of the river as a source of drinking water is receiving serious consideration, for this has long appeared to constitute a grave element of risk to the city.

*Willesden Urban District.*—Dr. Skinner aids his reader by an excellent table of contents. He discusses in some detail the questions of drainage and water-supply, and explains that offensive sewer emanations have been dealt with by means of high shafts. The general death-rate on a population of over 62,000 inhabitants was 13·8 per 1000 last year, and the zymotic rate was 1·6, a result that may on the whole be regarded as satisfactory. But when the zymotic diseases are considered, it becomes evident that the absence of any proper means of isolation is a source of great weakness in the sanitary circumstances of the place, and Dr. Skinner does not go too far when he foretells that possibly there may be an utter breakdown in consequence.

*Swinton Urban District.*—Dealing with the question of infantile mortality, Dr. Jones refers to the unsatisfactory term "convulsions" in death-certificates, a term which he finds to cover improper feeding, opium poisoning and allied neglect. The report deals mainly with special occurrences of disease and the statistical bearing of these. But it is added that the water-supply is deficient in quantity and not what it ought to be in quality. As so often happens in this neighbourhood, people cling to the antiquated practice of storing up in close proximity to their dwellings and windows heaps of excremental and other refuse to the extent in some cases of "hundreds of cubic feet" per midden. The system is barbarous and some of our northern towns reek with the consequent filthy odour in the neighbourhood of the backs of houses. The general death-rate was 20·1 and the zymotic rate 2·9 per 1000 living, both rates much too high for a small population of under 12,000.

*South Shields Urban District.*—Dr. Eustace Hill points out that during the year 1891 much active sanitary work was carried out. The notification of infectious diseases came into operation, active steps were taken to improve insanitary property, an assistant inspector was appointed, and a number of the abominable midden privies were abolished. Among the more pressing requirements of the borough are further additions to the inspectorial staff, new by-laws as to build-

ings, slaughter-houses, and offensive trades, and means for isolating cases of small-pox. The latter question is one which involves much difficulty; unless, indeed, some of the schemes by which the infected air of hospital wards is consumed within the building turn out to be feasible in practice, the general death-rate was 22.0 per 1000 living. Infectious causes to the number of 139 were isolated in the borough hospital.

*Igham Urban District.*—The population of this district was 4656 at the last census and the death-rate for 1891 was 19.7 per 1000. During the past two years the mortality rate has been excessive, but it is not always right to base too much on a rise, which may be temporary only, in such a small district as this. The zymotic diseases, indeed, caused but little death, whereas epidemic influenza is credited with an excess of deaths. Improvements as to the disposal of sewage are in contemplation and a new mortuary is in prospect. As regards general sanitary administration Mr. A. M. Eason's report must be looked upon as satisfactory.

*King's Norton Rural District.*—According to Mr. Hollinshead's last annual report the general rate of mortality for last year was 12.4 per 1000 on a population of 28,300, the zymotic rate being only 0.7; indeed this district has for many years exhibited a satisfactory saving of life in connexion with careful sanitary supervision. Scarlet fever was somewhat seriously prevalent, 109 cases being notified; but it is especially noteworthy that 95 of the cases in question were removed to the isolation hospital, and that Mr. Hollinshead is able to report a practical cessation of the epidemic. Drainage works are under consideration; much has been done in this matter as regards individual houses and as to local water-supplies; but the "worst of sanitary evils," the filthy midden-privy system of the old type, remains to foul the air and to constitute an incessant risk of disease. We earnestly endorse Mr. Hollinshead's plea for the abolition of these revolting structures.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6589 births and 3374 deaths were registered during the week ending July 30th. The annual rate of mortality in these towns, which had been 17.9 and 17.7 per 1000 in the preceding two weeks, further declined last week to 17.3. In London the rate was 17.5 per 1000, while it averaged 17.1 in the thirty-two provincial towns. The lowest rates in these towns were 6.3 in Burnley, 10.3 in Brighton, 11.8 in Croydon, and 12.9 in Gateshead; the highest rates were 20.5 in Salford, 20.6 in Leicester and in Wolverhampton, 22.8 in Sunderland, and 25.9 in Liverpool. The 3374 deaths included 585 which were referred to the principal zymotic diseases, against numbers increasing from 477 to 625 in the preceding five weeks; of these, 286 resulted from diarrhoea, 127 from measles, 56 from whooping-cough, 54 from scarlet fever, 41 from diphtheria, 18 from "fever" (principally enteric), and 3 from small-pox. No fatal case of any of these diseases occurred last week in Huddersfield; in the other towns they caused the lowest death-rates in Burnley, Hull, Newcastle-upon-Tyne, and Blackburn, and the highest rates in West Ham, Leicester, Sunderland, Cardiff, and Preston. The greatest mortality from measles occurred in West Ham, Croydon, Birkenhead, Salford, Halifax, and Sunderland; from scarlet fever in Preston; from whooping-cough in Swansea and Nottingham; and from diarrhoea in London, West Ham, Derby, Birmingham, Preston, Leicester, and Cardiff. The mortality from "fever" showed no marked excess in any of the large towns. The 41 deaths from diphtheria included 25 in London, 3 in Liverpool, 2 in West Ham, 2 in Norwich, and 2 in Manchester. Two fatal cases of small-pox were registered in Bradford and 1 in London, but not one in any other of the thirty-three large towns; 6 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 3 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2864, against numbers increasing from 1226 to 2671 on the preceding eighteen Saturdays; 382 new cases were admitted during the week, against 323 and 382 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 185

to 158 in the preceding four weeks, further fell to 155 last week and were 23 below the corrected average. The causes of 55, or 1.6 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Portsmouth, Norwich, Bradford, Newcastle-upon-Tyne, and in seven other smaller towns; the largest proportions of uncertified deaths were registered in Croydon, Birmingham, and Liverpool.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17.2 and 18.4 per 1000 in the preceding two weeks, declined again to 17.5 during the week ending July 30th, but slightly exceeded the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13.4 in Leith and 14.3 in Aberdeen to 19.4 in Glasgow and 22.3 in Greenock. The 488 deaths in these towns included 19 which were referred to measles, 14 to whooping-cough, 10 to diarrhoea, 5 to "fever," 3 to diphtheria, 3 to scarlet fever, and not one to small-pox. In all, 54 deaths resulted from these principal zymotic diseases, against 62 and 66 in the preceding two weeks. These 54 deaths were equal to an annual rate of 1.9 per 1000, which was 1.1 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of measles, which had been 13 and 28 in the preceding two weeks, declined again last week to 19, of which 11 occurred in Glasgow and 6 in Aberdeen. The deaths referred to whooping-cough, which declined from 27 to 13 in the previous five weeks, were 14 last week and included 11 in Glasgow. The 10 fatal cases of diarrhoea corresponded with the number in the preceding week and included 7 in Glasgow. The deaths referred to different forms of "fever," which had been 2 and 5 in the previous two weeks, were again 5 last week, of which 2 occurred in Glasgow. The deaths from diphtheria, which had been 7 and 5 in the preceding two weeks, further declined last week to 3, of which 2 were recorded in Leith. The 3 fatal cases of scarlet fever also showed a decline from recent weekly numbers and included 2 in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 71 to 59 in the preceding three weeks, rose again last week to 114, and were 49 above the number in the corresponding week of last year. The causes of 44, or 9 per cent., of the deaths in the eight towns last week were not certified.

### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24.2 and 19.8 per 1000 in the preceding two weeks, rose again to 28.3 during the week ending July 30th. During the first four weeks of the current quarter the death-rate in the city averaged 23.5 per 1000, against 18.2 in London and 16.4 in Edinburgh. The 190 deaths in Dublin during the week under notice showed an increase of 57 upon the number in the preceding week, and included 8 which were referred to measles, 3 to diarrhoea, 1 to whooping-cough, 1 to "fever," and not one either to small-pox, scarlet fever, or diphtheria. In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.9 per 1000, the zymotic death-rate during the same period being 3.7 in London and 1.2 in Edinburgh. The fatal cases of measles, which had steadily declined in the preceding six weeks from 27 to 7, were 8 last week. The 3 deaths referred to diarrhoea were within 1 of the number in the previous week. During the first four weeks of the current quarter the rate of mortality in Dublin from the principal zymotic diseases has not exceeded 2.2 per 1000, while it averaged 4.9 per 1000 during last quarter. The 190 deaths registered last week in Dublin included 35 of infants under one year of age and 41 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons exceeded the number recorded in the preceding week. Ten inquest cases and 9 deaths from violence were registered; and 75, or more than one-third, of the deaths occurred in public institutions. The causes of 21, or 11 per cent., of the deaths in the city last week were not certified.

### CALCUTTA.

According to the latest reports from Calcutta—viz., the health officer's sick return for the week ending May 28th

last—the total number of deaths registered was 206, against 219 and 270 in the two preceding weeks, and lower than the corresponding week of last year. There were 37 deaths from cholera, against 39 and 55 in the two preceding weeks; only 1 death from small-pox and 3 from tetanus. The general death-rate of the week was 23·0 per 1000 per annum against 20·1, the mean of the last five years. The total number of deaths in the amalgamated area of suburbs for the same week was 119. There were 16 deaths from cholera against 44 and 38 in the two preceding weeks; the number is lower than the average of the past three years. There were no deaths from small-pox. The general death-rate of the week was 28·8 per 1000 against 31·2, the mean of the last three years. The general death-rate of the combined area is equal to 24·8.

## THE SERVICES.

### NAVAL PRACTICE IN THE LANDING OF WOUNDED.

OUR contemporary the *Army and Navy Gazette* reports that recently and for the first time in the German Navy there has been a special exercise in the landing of wounded. The experiment took place at Kiel in the presence of the Emperor and the Grand Duke of Mecklenberg-Schwerin. Admirals Von der Goltz and Knorr with Dr. Wenzel, surgeon-in-chief to the Imperial Navy, were officially present. The idea was that the squadron had just suffered heavy loss in an engagement and that four line-of-battle ships had arrived at the port each with 500 wounded. The wounded were transferred to four steam transports and carried, under the care of the naval surgeons and attendants to four appointed places on shore, where they were placed in ambulance waggons and taken to the hospitals. This manœuvre in medico-naval drill is said to have been well and promptly executed.

### MAGAZINE RIFLE FIRE.

The Intelligence Department of the Horse Guards has published a paper giving details of the experiments recently carried out at Spandau to illustrate the effect of German rifles. The experiments were undertaken at the suggestion of the Surgeon-General of the Army and conducted in the presence of a number of army surgeons.

### MOVEMENTS OF THE MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel Ferguson has arrived from Gibraltar and been posted to Portsmouth for duty. Surgeon-Lieutenant-Colonel Barrow has arrived in England on completion of a term of service in Hong-Kong. Brigade-Surgeon Temple has been appointed to succeed Surgeon-Major Roe on the recruiting staff of the London district. The deaths of Surgeon-Captain W. H. Bennet and W. H. Ball are reported. Surgeon-Major Wolseley has arrived at Chester for duty and Surgeon-Captain Wills at Burnley. Brigade-Surgeon-Lieutenant-Colonel Kilroy has been transferred from Limerick to Dublin. Surgeon-Captain Hubbard has joined at Woolwich from the Western district. Brigade-Surgeon-Lieutenant-Colonel Maunsell has left Mauritius for England on being relieved by Brigade-Surgeon-Lieutenant-Colonel Clapp. Surgeon-Major Chester has resumed his duties in Egypt from leave. Surgeon-Captain Swan has reported himself in Dublin on return from temporary duty.

For the first time, as we believe, for many years, the ratio of competitors for the British and Indian Medical Services, severally, is the same, there being two candidates for each appointment. There can be no doubt that the issue of the new rule limiting the number of occasions on which a candidate may compete to two for each Service has kept down the supply of competitors by excluding several who had no chance of success, and probably to this fact rather than to any decline in the popularity of the Services may be attributed the reduction of the aspirants.

### ARMY MEDICAL DEPARTMENT.

Brigade-Surgeon-Lieutenant-Colonel William Johnston, M.D., leaves on retired pay (dated Aug. 3rd, 1892).

### ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major George S. Elliston to be Surgeon-Lieutenant-Colonel (dated Aug. 3rd, 1892). Brigade-Surgeon-Lieutenant-Colonel J. S. MacAdam, Army Medical Staff, attains the age of fifty-five on the 3rd inst., and will be placed on retired pay. The Commander-in-Chief has sanctioned an exchange between Captain J. Flint, 1st Dragoon

Guards, and Captain H. P. Levita, 4th Dragoon Guards. Major G. V. Ames, 1st Dragoons, is, on the completion of seven years' service as a Regimental Major, accepting promotion to a half-pay Lieutenant-Colonelcy. Brigade-Surgeon-Lieutenant-Colonel W. Johnston of the Army Medical Staff, is retiring from the Service. Surgeon-Lieutenant-Colonel C. E. Dwyer, now with the Medical Staff in London, has been ordered to join the staff in Ireland. The following Surgeon-Captains of the Army Medical Staff, having completed, on the 31st ult., twelve years' service, attain promotion to the rank of Surgeon-Major:—G. H. Sylvester, W. J. Macnamara, D. O'Sullivan, E. O. Milward, C. R. Woods, M. F. Macnamara, J. O. G. Sandiford, R. L. Love, H. W. Murray, M. W. Kerin, A. Peterkin, J. Harran, E. L. Maunsell, W. Heffernan, R. W. E. H. Nicholson, J. G. W. Crofts, W. Dugdale, D. L. Irvine, E. R. Cree, M. O'C. Drury, J. H. Nicholas, D. F. Franklin, and H. Saunders.

### INDIAN MEDICAL SERVICE.

Surgeon-Lieutenant-Colonel S. M. Salaman, M.D., and Surgeon-Captain H. W. Stevenson respectively delivered over and received charge of Yerrowda Central Gaol on July 5th, 1892. Surgeon-Captain J. K. Kanga, of the 17th Regiment Madras Infantry, to the officiating Medical Charge of the regiment. Brigade-Surgeon-Lieutenant-Colonel S. B. Hunt, Surgeon, 3rd district, to be officiating Principal Medical Officer, Rangoon district during the absence on furlough of Surgeon-Colonel C. Sibthorpe. Surgeon-Major J. Anderson, M.B., Civil Surgeon, Bareilly, is appointed to be in Visiting Medical Charge of the Budau district during the absence on leave of Surgeon-Major J. C. C. Smith, M.B. Surgeon-Captain H. E. Drake-Brockman, Civil Surgeon, is transferred from Etah to Mirzapur, on being relieved by Mr. W. H. Harding. Surgeon-Captain C. H. Leet Palk is appointed to be, from May 17th, 1892, Civil Medical Officer, Mandalay Shore, in addition to his military duties, vice Surgeon-Captain S. C. Dallas, transferred. Surgeon-Captain W. D. Sutherland is appointed to be, from April 21st, 1892, Civil Medical Officer, Fort White, in addition to his military duties, vice Surgeon-Captain C. L. Williams, transferred. Surgeon-Captain H. W. Pilgrim, Second Resident Surgeon, Presidency General Hospital, is appointed to act as First Resident Surgeon of that institution during the absence on leave of Surgeon-Captain J. H. T. Walsh, or until further orders.

Brigade-Surgeon-Lieutenant-Colonels Flemming and Cullen have been awarded the two extra pensions of £100 per annum allotted to Bengal during 1892-93, both having recently retired from service.

Surgeon-Captain Wilson, Indian Medical Service, died at Mandalay of cholera. This is the third officer who has died at Mandalay within the fortnight.

NAVAL MEDICAL SERVICE.—Surgeon Eric E. Kershaw to the *Nelson*, lent (dated July 26th, 1892).

VOLUNTEER CORPS.—*Artillery*: 6th Lancashire: Surgeon-Lieutenant R. H. Jones resigns his commission (dated July 30th, 1892).—1st Cheshire and Carnarvonshire: Surgeon-Lieutenant D. L. Hubbard resigns his commission (dated July 30th, 1892).—*Infantry*: 2nd Volunteer Battalion, the East Yorkshire Regiment): Surgeon-Captain W. Stephenson to be Surgeon-Major (dated July 30th, 1892).—4th Volunteer Battalion, the Cheshire Regiment): Surgeon-Captain K. Maclean resigns his commission (dated July 30th, 1892).—1st Volunteer Battalion, the Duke of Wellington's (West Riding Regiment): Surgeon-Lieutenant E. D. Wellburn resigns his commission (dated July 30th, 1892).

### THE LATE SURGEON-GENERAL H. W. BELLEW, C.S.I., C.I.E.

We regret to announce the death of this officer of the Indian Medical Service at Farnham Royal, Bucks, on the 26th ult., aged fifty-seven. He was a distinguished Oriental scholar, a man of indomitable energy and industry, a great traveller, and well known as an able political officer and linguist. His career was altogether a remarkable one, and worthy of the Anglo-Indian school to which he belonged. He had a great taste for historical, antiquarian, and ethnological subjects, an aptitude for acquiring languages and a keen appetite for hard work of any kind. The services of a political nature he rendered to the Indian Government were so many and marked that it is surprising that they did not attract more notice and receive greater reward. He was the son of the late Major H. W. Bellew, Assistant Quarter-master-General of the Indian Army. In 1854 he went to

the Crimean war, and in 1856 to India, where he joined the Guides, and was sent on the mission to Candahar, of which he subsequently published an account. He did good service in the Ambeyla campaign. In 1871 he accompanied Sir Richard Pollock on a political mission to Seistan and proceeded to the Persian capital. In 1873-74 he went on the Embassy to Kashghar and Yarkand. Selected for the purpose by the late Lord Lytton, he filled the post of chief political officer at Cabul during the Afghan war in 1879. He possessed and exercised much influence with the hill tribes. He was afterwards Sanitary Commissioner for the Punjab, and in 1885 he published a large volume of nearly 1000 pages on the history of cholera in India, but it was not as a doctor that he won his spurs and his name. His published works were "From the Indus to the Tigris," a narrative of a journey through Belochistan, Afghanistan, Khorassan and Iran in 1872, with a grammar and vocabulary of the Brahoe language; "Kashmir and Kashghar," a narrative of the journey of the Embassy; "The Races of Afghanistan"; and a dictionary and grammar of the Pukhto—or Pukshto—language. The late Surgeon-General was married to a sister of that thorough soldier, General Sir Charles MacGregor, whose relatively early death in Egypt a few years ago was regarded as a great loss to India.

THE LATE DR. JOHN FORBES WATSON.

We regret to announce the death of Dr. Forbes Watson, M.A., M.D., LL.D., on the 29th ult., after a protracted illness. The late officer belonged to the Bombay Medical Service, which he joined in 1850. He was educated at the University of Aberdeen, of which he was a graduate. Whilst in India he served on the Scinde frontier and afterwards filled the post of lecturer on Clinical Medicine at Grant College, but ill-health compelled him to return to England. At home he took up a number of questions—all of some public utility and some of them important. On his recommendation a commission was appointed to inquire into the nutritive value of the food grains of India. A large amount of valuable information was obtained, which led to several practical reforms. In 1858 he was appointed reporter on the products of India and director of the Indian Museum, and he acted as referee to the Secretary of State on all questions connected with Indian products and manufactures. He took an active part in most of the international exhibitions of late years, and his labours in this and other respects connected with India and the Indian Museum prepared the way for the Imperial Institute. In 1879 his department was broken up and he retired from the service. He was a man of scientific attainments and great knowledge of all subjects connected with India, more especially in relation to its industrial, commercial, artistic and ethnological aspects.

GUARDS BARRACKS AT BERLIN.

The Army Medical Blue-book just published contains a paper on the progress of hygiene for the year 1891 by Brigade-Surgeon-Lieutenant-Colonel J. Lane Notter, Professor of Military Hygiene at Netley, in which, among other subjects, allusion is made to the barracks of the 3rd Regiment of Guards at Berlin. The barrack buildings enclose a large square, which serves as a parade ground. They are described as compact and well built and arranged on the corridor system—i.e., all the rooms open on to corridors running the whole length of the building. The rooms are small and do not appear to be well ventilated. The men sleep in cots arranged in double tiers on one side of the room. The only ventilation aperture seems to be in the lower panel of the door opening on to the corridor and the openings of the windows. The allowance of air space for each man is not more than 16 cubic metres.

ARMY MEDICAL SCHOOL, NETLEY.

The sixty-fourth session of this school was brought to a close last week, when the distribution of prizes took place, Colonel Hanning Lee, late Assistant-Adjutant-General, Netley, performing the ceremony. The proceedings were carried out in the Lecture Theatre of the Royal Victoria Hospital, in the presence of a numerous gathering of the staff connected with the hospital, together with the ladies of their families and friends of the Army Medical School, including Colonel H. A. Bushman, C.B., Assistant-Adjutant-General; Surgeon-Major-General G. L. Hinde, C.B., Principal Medical Officer; Sir Joseph Fayer, K.C.S.I.; Sir Thomas Longmore, C.B.; Surgeon-Major-General S. A. Lithgow, C.B., D.S.O.; Surgeon-General Crookshank, Deputy-Surgeon-General

H. Cayley, Surgeon-Colonels Hamilton and Godwin; Lieut.-Colonels Haldane and Stokes and the other members of the Army Medical Staff stationed at Netley. Professor J. Lane Notter announced that all the gentlemen who presented themselves at the recent examination, both for the Indian and British services, had qualified for commissions. He then read the following lists of Surgeons on probation who were successful at both the London and Netley examinations. The prizes are awarded for marks gained in the special subjects taught at the Army Medical School. The final positions are determined by the marks gained in London added to those gained at Netley.

INDIAN MEDICAL SERVICE (Seventeen).

Smyth, W. J. . . . .	4820		

\* Gained the Herbert Prize of £20.

† Gained the Montefiore Second Prize.

Colonel Hanning Lee then distributed the prizes and said he should like to thank the Senate and officers and members of the school for their kindness in asking him to come to present the prizes. He hoped that every officer he saw before him, whom he was sorry to part with and whom he sincerely congratulated, would be far more successful even than they had been at Netley. Dr. Alchin pointed to the different circumstances under which the profession was learnt by the private and the military doctor and alluded to the disadvantages met with in civil practice as compared with military practice. Sir Joseph Fayer also spoke and, in the course of some eminently practical remarks, paid a touching tribute to the memory of the late Sir William Aitken, whose form, he said, seemed to rise before him there. The guests then adjourned to the Medical Staff Mess for afternoon tea.

THE CHAIR OF PATHOLOGY AT NETLEY.

We have already directed attention to the question of the professorships at Netley as affecting the interests of both the Army Medical Service and its school; and we then said that it seemed to us to be distinctly in the interest of the public service that such professorships should be regarded as prizes for medical officers who should be encouraged to develop a high standard of professional knowledge, and qualify themselves for appointments in their own special institutions. If we may judge from the communications we have received on the subject of the appointment of the late Sir William Aitken's successor at the Army Medical School it is causing strong dissatisfaction in the minds of many medical officers. Against the personal, scientific and professional qualifications of the gentleman nominated there is not a word to be said; they are undoubtedly of a high order; but that is not the question; it is one of principle. It is not pathology in its general sense, such as is taught at our medical schools and Universities, that is the point at issue; the appointment at Netley is a special one and has for its main object the consideration of climatic and other forms of disease incidental to military life and service, concerning which, it is urged, army medical officers must be better qualified, from the nature of their duties and personal experience, to speak than a civilian without these advantages. The views of the founders of the Army Medical School were

evidently in accordance, too, with those we have expressed above. At the time the school was moved from Chatham to Netley, early in the year 1863, they reported they were all agreed that the professorships should be held by army medical officers when men of sufficient competence offered themselves, and they trusted that they would all be so held when it could be done with advantage to the school. These views received the approval of the then Secretary of State for War. The question about the successorship to a post at Netley resolves itself, therefore, into whether there are medical officers of sufficient competency in the army or among those who have retired from it. It cannot, surely, be seriously maintained that among the ranks of the Indian and British medical services no one could be found to fulfil all the requirements of the post in question.

### CLASSICAL CULTURE AND THE PROFESSION.

To the Editors of THE LANCET.

SIRS,—I hope it may not be thought captious, as it certainly is not superfluous, to point out an important error into which Professor Cuming has been betrayed in the course of his admirable Address in Medicine at the late meeting of the British Medical Association. "I come to bury Cæsar, not to praise him" is a text which would fairly describe Professor Cuming's attitude towards the two learned languages which for so many centuries have formed the basis and the instrument of intellectual culture throughout Europe, and which are inextricably interwoven with the structure of all scientific language—not least with that of Medicine itself. Still it may be that the tendency of events is, as Dr. Cuming alleges, that the mental condition of our professional successors will be one of complete denudation as regards all knowledge of Greek and Latin, as well as of Chemistry. These are debateable points, and I trust their realisation may be as far distant as the exhaustion of our coal fields or the approach of a glacial epoch; but that to which I desire to call attention is not debateable, though it is unfortunately obscured by certain inveterate and long-standing prepossessions in the minds of the educated public. "Greek seems doomed past recall," says Dr. Cuming: "Latin will make a harder fight to retain its place, and will probably succeed in retaining it." Now, these are certainly very curious *obiter dicta* on the part of a speaker who shows so much evidence of learning and culture as Dr. Cuming, seeing that Latin is a hopelessly dead language, while the tongue of Greece is as much alive and as unbroken in its continuity as that of England. Greek at the present day is not only the national speech of the Hellenic kingdom, but is the universal daily medium of communication throughout the east of Europe and a large part of Asia; in Egypt it is more generally spoken than any language except Arabic; numerous excellent journals possessing a wide circulation are printed in it, and it can boast a considerable current literature both in serial and book form. A distinguished Hellene has lately translated the whole of Dante's "Divine Comedy" into Greek, and this very year the University of Edinburgh has established a fund for the purpose of enabling a certain number of its students to go to Athens to acquire the native tongue. These facts do not look like the symptoms of approaching dissolution, but, on the contrary, betoken healthy growth and vitality; and I hope they may serve as an adequate excuse for my entering a *caveat* against Professor Cuming's too sweeping generalisation that "Greek seems doomed past recall."

I remain, Sirs, your obedient servant,  
Sussex Gardens, July 31st, 1892.

T. FITZ-PATRICK.

### VACCINATION AND PUBLIC SCHOOLS.

To the Editors of THE LANCET.

SIRS,—It may possibly prove interesting to some of your readers to learn the result of an inspection of a large number of children attending the public elementary schools of this

town. The Cardiff board of guardians, having received information that small-pox in an epidemic form had occurred in various parts of the kingdom, instructed the public vaccinators to visit the schools and inspect the children's arms with a view of discovering those who had escaped vaccination. The School Board and the managers of the sectarian schools readily gave their assent to this course, and the various masters and mistresses cordially assisted me in my work. Altogether the number of children inspected by me amounted in round numbers to 8000, and the total number of those children who had no marks whatever amounted to 270. The parents of these were communicated with by the vaccination officer, and most of them have complied with the notices served on them. In addition to those who had no marks of any kind there were at least 15 per cent. of the total number who had either very imperfect marks or only one or two well-defined marks. Although the latter could not be said to be well protected, it was thought advisable only to recommend their parents to have them revaccinated. I apprehend there would have been some difficulty if these imperfectly vaccinated children had been ordered to be vaccinated again. It was an easy matter to distinguish those children who had been vaccinated at a public vaccination station from those who had been done by private practitioners. I am more than ever convinced that all vaccination should be in the hands of gentlemen specially appointed for the purpose and who should at the same time be restricted from practising any other branch of the medical profession. Until some scheme of that kind is adopted we can never expect to find the public properly protected from the ravages of small-pox. At the present time private practitioners are somewhat jealous of the public vaccinators; but if they (the private practitioners) could be assured that there was no chance of their patients being interfered with this jealousy would soon cease to exist. There would not be any great difficulty in carrying out such a scheme if the medical profession were in favour of it. The public must not have any ground of complaint. Their children would not be operated upon unless the sanction of their family doctor had been obtained, and they would have the satisfaction of knowing that the operation had been thoroughly well done. Those who wished to have their children done privately could still do so on paying a stipulated fee, and it would be easy to arrange for vaccination direct from the calf at regular times.

I am, Sirs, yours faithfully,

Cardiff, July, 1892.

T. GARRETT HORDER.

### THE DIAGNOSIS OF HEAD INJURY FROM DRUNKENNESS.

To the Editors of THE LANCET.

SIRS,—In looking over some of the back numbers of THE LANCET I notice an article by Dr. J. H. Waters (Sept. 26th, 1891) regarding the difficulty of diagnosis of head injury in police practice and his method of removing the effects of alcohol sufficiently to permit of a diagnosis. As he suggests, a cell, or even a police station, is not a good place to form a correct diagnosis, and the frequency with which one finds symptoms very much obscured by alcohol is well known to police surgeons. A method which I employed while engaged in a very active emergency service in New York City, and which to-day is in extensive use in this class of cases, answers every purpose desired, and is more easy of application and devoid of the danger attendant upon the inhalation of ammonia. By pressure upon the supra-orbital notches, compressing the nerve, a diagnosis of alcoholism may with absolute certainty be made in a few seconds, thus differentiating on the spot between coma due to alcoholism, injury or disease. Where no result is obtained, one may, with almost positive certainty, look for some other cause of coma. In no case have I failed with this method, and so certain became I of its infallibility that, without waiting to further examine for head injury where no result was obtained, I took the patient to the hospital sure of a "case." A case of alcoholism pure and simple will, upon the application of this pressure, immediately show very evident signs of life, and, be the coma ever so deep, the effect of the alcohol will for a short time be sufficiently removed to permit a thorough and rapid examination. The absence of result from this method should at once cause great suspicion of some cerebral trouble due to injury or disease. I would add, that to quiet hysterical convulsions,

in hiccough, in alcoholic mania and for the detection of emalingerers, there is, to my mind, nothing superior.

I am, very truly yours,

L. L. VON WEDEKIND, M.D., U.S. Navy.

U.S. Naval Hospital, Chelsea, Mass.

## PERFORATION OF INTESTINE IN TUBERCULOUS PERITONITIS.

To the Editors of THE LANCET.

SIRS,—The interesting paper by Drs. Fenwick and Dodwell, which appeared in THE LANCET of July 16th and 23rd has recalled to my mind a paper I read before the Leeds and West Riding Medico-Chirurgical Society two winters ago on "Four Cases of Tuberculous Peritonitis, three being treated by Operation," and some suggestions I ventured to make upon them. Two of the cases, one operated upon by Dr. Kilner Clarke and the other by myself, died, the first some six weeks later of fœcal fistula, which developed before the abdominal incision had healed my own case, some months after operation, rupture of the intestine and of the abdominal wound occurring three months after the latter had soundly healed and the patient had been going about. In my case and another on which I successfully operated about the same time diarrhoea was a marked symptom, which nothing in the way of treatment seemed to control. Immediately I had cleaned out the abdomen, however, the diarrhoea ceased and did not recur, the recovery being uninterrupted. I asked if this was commonly the case and if it was unreasonable to suppose that the presence of pus in the peritoneal cavity had not set up such irritation of the intestine as would encourage a settlement of bacilli in an exhausted area, which would be more liable to fall a prey to the germ under these conditions. That there is a close physiological connexion between the peritoneum and the intestines there can be no doubt, and, directly or indirectly, the bowels remove the fluid collections from the peritoneal cavity as from other parts of the body. The singular and immediate cessation of diarrhoea in these and other cases of the operation, the steady improvement in most up to a certain point, seem to lend plausibility to the idea that the intestine being relieved from its overwork is either protected from the formation of a tuberculous ulcer, or is enabled to throw off the disease and recover itself if the products of tuberculous inflammation are removed from the peritoneal cavity before the process has gone too far. In the two cases first quoted this was evidently not the case, but in the second case it was almost done soon enough.—I am, Sirs, yours truly,

GEORGE A. HAWKINS-AMBLER, F.R.C.S. Edin.

July 20th, 1892.

## "THE SMOKE NUISANCE IN LONDON."

To the Editors of THE LANCET.

SIRS,—So far from an apology being necessary for introducing at this season the subject of the smoke nuisance in London, I think the community should thank you for the timely remarks of your leading article, for it is now that one of the chief remedies indicated can be most easily applied—the substitution, namely, of gaseous for solid fuel in our houses. Everyone who takes an interest in this important question is aware that many methods have been proposed for obviating the intolerable evils of London smoke fogs. But of all these there can be no doubt, it seems to me, that, according to our present knowledge, means and opportunities, the adoption of gas fires is the most feasible, and one which there is no difficulty in applying during the summer months, when fires are not being burnt. If householders are to wait before adopting a new plan till some ideally perfect substitute is invented for the barbarous and wasteful coal fire, the Greek kalends will be here before London is freed from its annually thickening pall of winter filth. I would therefore urge every inhabitant of this great city to combine to relieve it of what is little short of a disgrace to its appearance and a slur on its reputation. This could be done by bringing pressure to bear on the County Council and the metropolitan M.P.'s, whose successful endeavours would stamp them as true public benefactors. It is wonderful that enthusiasm has not been already aroused. The evils of London smoke and smoke fogs are universally admitted and bewailed: the damage to valuable books, furniture and pictures, the grimy appearance of our public edifices, the greasy black mud of

our streets, the flight of wealthy people from town for many months, the gloomy depressing skies, the choking atmosphere, the pallid looks of the regular denizen, the direct injury to health, increased mortality, the interruptions to traffic, the loss to trade, the dangers of accident, the encouragement of crime, the diminution of sunlight, the consequent decrease of animal and vegetable vitality and other almost innumerable bad results. Is it not strange, then, that the community, though loudly complaining, takes no active steps to heal this ever-magnifying sore? London, which from its size, wealth, position and constitution, is the leading city in the world, seems content at the same time to remain, at least during winter, the most hideous and repulsive. I would appeal especially to the medical profession, which in the past has conferred such immense boons on the people by teaching the remedy for various dangers to the public health, to continue its philanthropic efforts in dealing with the nuisance of London smoke. The field may be wide, but it is worthy the attention of scientific men. There is no reason why the metropolis should not all the year round be one of the fairest and most attractive of towns, and it is equally certain, while coal is consumed in our grates, that it will remain the very reverse.

I remain, Sirs, yours faithfully,

Thurloe-place, S.W., July 20th, 1892. H. R. OSWALD, M.D.

## "THE SIGNIFICANCE OF FLY BITES."

To the Editors of THE LANCET.

SIRS,—Having read your annotation on the above subject in THE LANCET of July 23rd, I think the following case may be of some interest to your readers.

S. W—, aged twenty-five, was admitted to the Devon and Exeter Hospital on July 11th, under Mr. Bell, with the following history. He was a compositor by trade. Eight days previously, when at a breakfast, he was bitten on the proximal phalanx of the left index finger by a fly, presumably a gad-fly. No notice was taken at the time, but the finger began to swell and the wound to ulcerate, and for three days before admission he had had great pain. On admission the man looked very ill indeed. Temperature 103.6°; respiration 60; perspiring freely. On the finger was a yellowish sloughing wound the size of a two-shilling piece; the hand was swollen and œdematous; there was well-marked cellulitis up the arm; no swelling in the axilla. Examination showed pleurisy at the left base of the lungs. Mr. Bell made free incisions into the arm and wound and ordered copious stimulation; but in spite of all efforts the patient died within eleven hours of admission, apparently of acute septicæmia. Post-mortem examination showed a very fluid condition of the blood and all the organs macroscopically healthy, with the exception of the lungs, which were riddled with very large infarcts and where there was extensive pleurisy at the base. The case is interesting in view of the sad occurrence reported in a former number of THE LANCET.

I am, Sirs, yours faithfully,

Exeter, July 26th, 1892. G. STEWART ABRAM, M.B., B.C.

## "CURES" FOR INEBRIETY.

To the Editors of THE LANCET.

SIRS,—Since Dr. Keeley's letter in your issue of July 30th utterly fails to deal with the real question at issue, I fear that most of your readers will consider it unworthy of any reply. As, however, he has introduced my name rather prominently therein and as entire silence on my part might under the circumstances seem strange, perhaps you will be good enough to grant me space for a few words. What I would say to Dr. Keeley is this: If his remedy is a genuine cure for inebriety, and on his own showing it has been used for thirteen years, why does he not prove its efficacy to the satisfaction of the profession in Great Britain by submitting it fairly and openly to the opinion of a committee of British physicians? Does he imagine for one moment that such a committee would refuse to recognise his work or the merits of his drugs, providing the claims he aims at establishing are sustained? Let Dr. Keeley approach the leaders of the profession here in a proper spirit, and he may rest perfectly assured of fair and unbiased treatment. Either his remedies are really useful and deserve praise, or they will not stand the light of investigation.

With regard to the latter alternative I need not proceed further. If the remedies are valuable, then the maintenance of the secrecy now shrouding them is, both professionally and scientifically, indefensible. Analyses, reported here and in America, have failed to detect gold in the composition of the mixtures sold, so that a lack of confidence in the whole system has arisen.

With regard to the charges of inaccuracy which he endeavours to advance as to the narrative of my visit to Dwight, I may mention that I propose dealing with that matter in my work on "Alcoholism and its Treatment," which will be published in a few days. Without bandying words with him, however, I beg to say that it is entirely incorrect that I have said that "three eastern physicians visited Dwight while I was there," &c., or "that I went there to purchase the right of using his remedies in Australia." If I had found that a new and successful treatment was in use there under the same circumstances of openness and professional rule as elsewhere, I should have been quite prepared to bring such treatment before the profession in Great Britain and Australia. I went to the place with that purpose in view and was disappointed with what I found. During the conversation with Dr. Keeley at Dwight he intimated that he would get his nephew (Dr. Keeley) to take me to the treatment hall. A little later we passed into the main building and met Dr. Blaine, "chief of staff," to whom Dr. Keeley introduced me. I accompanied Dr. Blaine to the treatment hall, the nephew having gone out. If Dr. Blaine was an "Irish bottle washer," he deserves praise for the position he has attained to. On the other hand, if he still is entitled to be called a "bottle washer" and fulfils the functions of "chief of staff" as well, he is to be congratulated on the infinite variety of his talents.—I am, Sirs, your obedient servant,

J. E. USHER.

Wimpole-street, W., Aug. 3rd, 1892.

\*\* A continuance of this correspondence would be as unsatisfactory to the disputants as it would be unprofitable to our readers. We have already, in our desire to be fair, accorded more space to these unprofessional methods of treatment than we had intended, and, so far as we are concerned, the correspondence must now definitely terminate.—ED. L.

## THE CHOLERA IN PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

DR. DAREMBERG, the well-known correspondent of the *Journal des Débats*, has had the courage to declare that genuine cholera prevails in Paris and the neighbourhood. A summary of his article has been telegraphed to the English press, and it completely confirms the information I had already forwarded some weeks ago. Dr. Daremberg says (and this was not mentioned in the telegraphic summary of his article) that Dr. Netter, working in Dr. Proust's laboratory, Dr. Chantemesse in Dr. Cornil's laboratory, and Dr. Roux at the Pasteur Institute, have all found, in the dejections of the Paris cholera patients, the comma bacillus which Dr. Koch discovered in India, which Dr. Straus found during the cholera epidemic at Toulon in 1884 and which Dr. Calmette is now cultivating in Cochin China. It is difficult to see what better proof is required than this; but it is urged that in some case the comma bacillus has not been present. Dr. Daremberg replies that this only shows that other microbes can produce the same choleraic symptoms. In this respect it may be mentioned that Dr. Peter, of the Necker Hospital, has also made bold to defy the authorities in their attempt to conceal the true character of the present epidemic. To him political and administrative considerations are of no concern—he has to deal exclusively with the scientific aspect of the question, and as a man of science he is bound to say that the cases described in official documents as "choleraic diarrhoea" present very clearly marked characteristics of Asiatic cholera. In Dr. Peter's laboratory the comma bacillus was discovered some time before it was found by Dr. Netter. It was on July 5th last that I wrote stating that the comma bacillus had been seen in the dejections of the patients; and in those days it was little short of high treason to make such an assertion. Now, however, its truth can no longer be denied.

Dealing with the cause of the epidemic Dr. Daremberg propounds a theory which is open to question. On the one hand he adopts the germ theory, and yet he condemns the irrigation works at Gennevilliers, where a third of the Paris sewage is utilised for agricultural purposes. He seems to think that sewage farms may become mere cholera beds; but the water of the Paris sewers, after it has been utilised for the fertilisation of Gennevilliers, is collected by underground drains and falls into a brook. On analysis this water is found to be absolutely free from microbes. It is drunk by the visitors who go to Gennevilliers. I have drunk the water and have seen hundreds of other people drink it. The water the people receive who have had the cholera is the water of the Seine and there the sewage has no means of purification, but mixes with the water or forms heavy deposits on either bank. Not only the present epidemic, but the epidemics of 1884 and 1866 commenced in the suburbs of the west of Paris; that is to say, in the districts situated near the portion of the river receiving the principal outfalls of the Paris sewers. The river, it seems, rather than the sewer farm, is the cause of contamination, particularly if we consider that this contamination occurred before the sewer existed.

The number of deaths from cholera in and about Paris are now supposed to exceed 400, yet the epidemic has not yet taken root in Paris itself. In the suburbs it exists only in the north and west of Paris, just by that bend of the Seine which seems to be especially contaminated; but within the walls of Paris the cases are scattered in every direction. For instance, there has been a death from cholera at No. 11, Rue des Isles in the Goutte d'Or district—that is the extreme north—and another at 63, Rue Blanche. This latter is in the centre of Paris and to the south of the other case. A man aged twenty-nine died in the Rue Tiphoin, at Grenelle (S.W.), and another in the southern centre of Paris, Rue Notre Dame des Champs. There have been deaths at 3, Rue Rennequin in the Ternes (N.W.); impasse Boudran in the extreme south of Paris; 31, Rue Francois-Gérard, at Auteuil, extreme S.E.; another at Grenelle in the same direction, but not so far. Then there were deaths at Clignancourt, Necker, Porte Dauphine, and Combat, districts which are respectively to the north, the south, the west and the north-east of Paris. I could continue the list, but I have mentioned a sufficient number of cases, all of them ending fatally, to show how scattered is the disease. It has not as yet created in Paris any particular focus, and the cases are as widely spread out in respect to time as they are geographically. This is very different to the experience of the epidemic of 1884 when once it got within the walls of Paris. The disease ran its course in the following manner:—On November 3rd, 1884, there was 1 death, on the next day 3 deaths and the day after 18. The number of deaths for each of the following days was as follows:—On the fourth day, 14; on the fifth, 28; and then, for each succeeding day, 76 deaths, 94, 97, 78, 83, 66, 70, 45, 36, 47, 28, 34, 26, 17, 19, 10, 14, 8, 3, 11, 2, 7, and after that at intervals, a few more cases bringing the total number of deaths up to 955, which, with the cases brought into Paris from the outskirts, made a grand total of close upon a thousand deaths. On that occasion the first cases in Paris occurred in the central districts of the Arsenal, near the Bastille; the Art et Metiers, close to the Boulevard Sebastopol; and the Halles. After that the asylum, or Hôpital Breteuil, in the south-west of Paris was infected and the rag-pickers' quarters in the Cité Jeanne d'Arc.

Warned by the past, the authorities have been looking sharply after the rag-pickers, and have discovered a nest of rag-sorters in the Clichy district, who were living in such conditions of filth and overcrowding as to seriously endanger the public health. These unfortunate people have received peremptory orders to quit their present quarters, and they have only been allowed ten days to remove. But they cannot find any other lodgings. No one will take rag-pickers as tenants; also their trade does not bring in sufficient profit to enable them to pay high rents. As it is, they only pay from 1s. to 2s. a week for a room and some 3s. a week for a ground floor of two rooms, where they accumulate and sort the rags, paper and the other refuse they pick up in the streets. It is difficult to blame these rag-pickers for their endeavours to utilise waste products; but undoubtedly they render the houses in which they live filthy and unhealthy. Such people fall ready victims to any epidemic—they were the principal sufferers at the last cholera epidemic—and it is only natural and right that the authorities should take measures against them. At the same time their lot is a hard

one, and it is with much pleasure that I am able to announce Baron Rothschild has sent £200 for their relief. The rag-pickers are certainly suffering for the public good, and it is only fair the public should come to their assistance.

Paris, Aug. 2nd.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

### *Sunderland Infirmary.*

THE ninety-third annual report of the Sunderland Infirmary has been issued. It states that 2065 in-patients were treated during the past year; of which number 1206 received surgical treatment (394 being from accidents of a serious nature) and 857 were medical cases. The mortality was 5.1 per cent. The number of out-patients treated (such as minor accidents &c.) was 2649. The total subscriptions received from the working classes amounted to £4403. The Sunday schools collection shows a gratifying increase of £39. The expenditure during the year was over £9260, an increase of £417, caused chiefly by certain alterations rendered necessary by the erection of the isolation block.

### *The New Infectious Diseases Hospital at Wallsend.*

The building of this hospital is being rapidly pushed forwards. The site of the new building which is being erected in accordance with a mutual agreement between the joint authorities of Wallsend, Willington Quay and Howdon, is on a breezy eminence about a mile on the north side of Wallsend and is equidistant from the joint townships named above. The erections within the enclosure cover two acres. I hope in a future letter to give you a fuller description of the hospital, which comprises four blocks of buildings.

### *The Walker Hospital.*

The annual meeting of the Walker Hospital has been held. This is principally a workmen's hospital, treating about 500 cases in the year, and it is pleasant to record that more than one-half of the income is derived from working men's collections.

### *Darlington.*

A great demonstration of the Darlington Friendly Societies was held on Sunday last in the public park, in aid of the Convalescent Home at Grange-over-Sands, which was in every way a success. I think, however, that the *Northern Echo* made the following remarks upon somewhat insufficient information, asking—viz.: "Where were the Darlington medicos yesterday? No doubt some had 'part work' to do. It seems odd that the good object sought to be attained by the gathering in the park was not better patronised by those who remained at home. I believe that very few got home from the meeting from such distant points as Darlington to commence their work on Sunday. Many on the other hand made Nottingham the starting point for their short and well-earned holiday. At a late meeting of the sanitary authority a letter was read from the Local Government Board with regard to a resolution passed by the authority asking the Board to withdraw measles from the list of infectious diseases (Notification Act), which stated that it appeared to the Board that the sanitary authority had not taken full advantage of the opportunity of repressing measles, and of instructing the people how they may themselves assist in checking its spread. The Board could not but think that if that had been done more satisfactory results would have been obtained.

### *Middlesbrough.*

The Middlesbrough Friendly Societies' demonstration in aid of the North Riding Infirmary, Ormsby Cottage Hospital and the Middlesbrough Nursing Association had to be abandoned owing to the inclement weather on Sunday last so far as the usual procession went, but a large and successful meeting was held in the Town Hall; so it is to be hoped that the local charities will not suffer.

### *Poisoning Cases.*

A fatal case of poisoning by carbolic acid has occurred

at Consett. A nurse, wishing to give a patient a dose of medicine (in the dark), gave carbolic acid instead. Death took place after much suffering in a few hours. A child aged six died in Newcastle the other day from hemlock poisoning. She and another child aged four were playing in a lane in one of our suburbs, where they saw some hemlock lying and, picking it up, ate a little of the flower; they became rapidly ill and the elder child expired in one hour. The other child fortunately vomited freely and was soon brought round. I do not remember a more rapid case than the above, but of course the plant is at its period of activity at present.

### *Asylum Accommodation in Yorkshire.*

At the latest meeting of the West Riding County Council Alderman Woodd moved that the Asylum Committee be empowered to provide additional accommodation at the Menston Asylum, in view of the increase in the number of pauper patients requiring care and treatment in the West Riding. The committee in its report expressed its belief that, though the number of such patients had risen from 3272 in 1890 to 3394 in the last year, "it would not be safe to assume an abnormal increase in lunacy in the West Riding." Mr. Woodd's resolution was adopted.

Newcastle-on-Tyne, Aug. 3rd.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

### *Congress of Sanitary Association of Scotland at Aberdeen.*

THIS annual Congress was held at Aberdeen on July 27th, 28th, 29th and 30th. The meeting on Wednesday was formal. On Thursday the Marquess of Huntley, honorary president of the Association, occupied the chair and delivered the opening address. He referred to the question of grants in aid of public health, holding that, in fairness to Scotland, such grants should be continued and even increased. He believed that if the powers conferred by the Housing of the Working Classes Act were more generally known, they would be taken advantage of by district committees and proprietors in removing insanitary dwellings and substituting good cottages in their place. He attributed a good deal of the immigration of rural labourers to the towns to the condition of their dwellings. Resolute progress had been made in sanitation; but the feeling that more could and ought to be done was spreading, and when really called into action would become an irresistible force. Four papers were read and discussed: Consumption in Relation to Public Health, by Dr. Neil Carmichael, Glasgow; The Period of Infectiousness in Scarlet Fever, by Dr. R. M. Beattie, Aberdeen; Worm Nodules in the Lungs of Sheep, by Dr. J. T. Wilson of Aberdeen University; and Diseases transmissible from the Lower Animals to Man, by Mr. J. McL. Young, M.R.C.V.S. of Dundee. On Friday, papers were read by Dr. Macdonald (Aberdeen) on Tuberculosis in Common or Barn-door Fowls; and by Dr. Rennet, (Aberdeen) on the Progress of Typhoid Fever in Aberdeen and other Principal Scotch Towns. After addresses by Mr. Gilbert Thomson (Glasgow) and Mr. K. Cameron (Aberdeen) a paper was read on the Progress of Cremation, by Mr. John Mann (Glasgow). This led to a motion being carried to the effect that cremation of the dead, especially in cases of infectious disease, was a rational hygienic process, and that local authorities should be empowered by Parliament to build crematoria. Saturday was devoted to the inspection of places and appliances of interest.

### *Aberdeen Medical Staff Corps.*

Last week fifty men of the 7th (Aberdeen University) Company, Volunteer Medical Staff Corps, left Aberdeen for a week's training at Aldershot. They were under the command of Surgeon-Captain MacGregor and presented a smart soldierly bearing as they marched from their new headquarters to the railway station.

### *Public Health Prosecutions at Aberdeen.*

A house proprietor was convicted last week of permitting drains to remain foul in his houses after repeated notices from the sanitary staff to get them cleaned. A light fine was imposed. Another householder at Torry was convicted of having failed to notify to the authorities the existence of cases of measles in his house. The magistrate dwelt on the

dangerous nature of the offence and imposed a fine of five shillings.

#### *The Health of Aberdeen.*

||The following is a return of the zymotic cases noted last week:—Town: Measles, 29; scarlet fever, 21; diphtheria, 2; whooping-cough, 25; erysipelas, 6; total cases, 83; being an increase of 31 as compared with last week. County: measles, 2; scarlet fever, 20; typhoid fever, 3; erysipelas, 1—total 26.

#### *Aberdeen University Medical Graduation.*

The ceremony of "capping" the successful students was performed on July 27th, when twelve gentlemen proceeded to the degree of M.D. and thirty to those of M.B. and C.M. Three gentlemen received the D.P.H. and one the degree of B.Sc. In addressing the graduates Principal Sir William Geddes spoke of the extension of the University buildings scheme. He mentioned that over £70,000 of the £80,000 required was already promised and that soon the scheme would be workable. He sketched the history of the scheme and warmly eulogised the various friends of the University who had furthered its interests.

#### *Graduation Ceremonial at Edinburgh University.*

Mr. Robert Murray Leslie, M.A., B.Sc., M.B., C.M., was awarded the Ettles Scholarship as the most distinguished graduate in Medicine, and the Stark Scholarship of £100 in Clinical Medicine. Mr. Leslie previously graduated M.A. and B.Sc., with the highest honours and obtained the Baxter Biennial Science Scholarship (of £142) as the most distinguished graduate in science.

Aug. 3rd.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

#### *Royal College of Surgeons.*

A MEETING of the Fellows will be held on Thursday, pursuant to the provisions of the Supplemental Charter, to witness the election of six examiners for the diploma in dentistry—viz., three Fellows of the College and a similar number of registered dentists.

#### *Death of Henry Croly, Sen., M.D., J.P.*

This gentleman died at his residence, Greenfield, Rathfarnham, on Sunday last, at the ripe age of eighty-six years. He was of a kind and genial disposition and enjoyed the respect and esteem of all with whom he came in contact. He practised for over half a century at Rathfarnham, where he was for many years medical officer of the district, and retired some years ago on superannuation. He enjoyed wonderfully good health and looked hale and hearty until shortly before his death. For some years he examined in midwifery in the Royal College of Surgeons. The deceased leaves two sons, both members of the profession—Henry Gray Croly, the well-known Dublin surgeon and late President of the College of Surgeons, and Albert Croly, medical officer to the Rathfarnham Dispensary.

#### *North Dublin Union.*

At a meeting of the guardians last week a communication was submitted from the Local Government Board enclosing a copy of orders which they had put in force, prohibiting the importation of rags into Ireland from France, the ports of the Black Sea, the Sea of Azov, and parts of Turkey in Asia. They requested the Board to see that the orders were carried out by the medical officers of the union.

#### *Health of Dublin for June Quarter.*

The births registered in the Dublin registration district for the June quarter numbered 2625, or 30 per 1000, while the deaths amounted to 2730, or 31·2, the rate being 4·6 over the average for the quarter. Zymotic diseases caused 502 deaths, or 23 above the previous quarter, the rate being 4·1 above that for the corresponding quarter of last year. Over 64 per cent. of the total number of deaths from zymotic diseases was due to measles, which caused 322 deaths, the disease being far more fatal in the city than in the suburbs. Whooping-cough caused 60 deaths, against 73; enteric fever 14, a decided decline; typhus fever 4, or an increase of 3; while scarlet fever only caused 1 death, against an average of 23. Among the remaining deaths from zymotic diseases were 27 from influenza, 4 from

diphtheria and 18 from diarrhoea and dysentery. In 249 instances the cause of death was not certified and of these 180, or 72 per cent., were deaths of children under five years of age, these 180 deaths forming 17·5 per cent. of the total number of deaths of children of that age. Of the deaths of 115 children under one month old registered, there were 55, or 48 per cent., in which the cause was uncertified.

Sir W. Stokes has been appointed surgeon-in-ordinary to the Queen in Ireland, in the room of Mr. Colles, deceased.

The Local Government Board will hold an inquiry in Drogheda next week regarding the alleged insanitary condition of Chord burial ground.

Aug. 3rd.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *Artificial Feeding of Infants.*

M. BUDIN has lately conducted some experiments on the above subject in his wards at the Charité Hospital, and communicated the results to the Académie de Médecine on the 19th ult. The system followed in his practice is to administer to all the newborn children, for the first three days, cow's milk sterilised by means of Soxhlet's apparatus; this sterilised milk supplementing or replacing the maternal supply according to circumstances. The milk is given undiluted with water. Should the quantity of the mother's milk be sufficient the artificial product is not given. If the maternal supply is deficient, or absent, the sterilised milk is continued wholly or partially. Notes were taken of these three categories of infants under observation from April 1st to June 28th, 1892. Of 89 fed exclusively at the breast after the third day the average daily gain of weight was 28 grammes 17 centigrammes. The average daily gain of weight from the second day of 91 infants submitted to the mixed diet was 18 grammes 16 centigrammes, the corresponding average in 11 infants fed on sterilised milk only being 14 grammes 24 centigrammes. The average daily increase in weight for the 191 infants, taken together was 22 grammes 59 centigrammes. Of the 89 breast-fed children 6 had diarrhoea, whilst 7 such cases occurred amongst the 91 mixed-diet infants and none amongst the 11 artificially fed. In no instance was the diarrhoea severe, and all the little patients recovered. It will be noticed that the development of the nursing, as judged by the daily increase in weight, was most marked in the case of the breast-fed, less in the partially breast-fed and least of all in the artificially fed. The total absence of gastro-enteric complications amongst the children brought up exclusively on sterilised cow's milk is an important feature of M. Budin's communication. That physician is, however, very emphatic in his preference for breast feeding and pronounces strongly in favour of daily weighings as being the most reliable means of ascertaining its physical progress.

#### *Treatment of Fractures of the Patella.*

M. Berger related to the Société de Chirurgie the details of an operative procedure for procuring osseous union in fracture of the knee-cap. The subject of the operation was a little girl whose patella was fractured transversely, the upper fragment comprising four-fifths of the bone. The limb was put up in a plaster-of-Paris splint and maintained in a raised position. No union having taken place at the end of forty days, suture of the fragments was decided upon. Unfortunately, after the opposed surfaces of the parts had been pared, the lower and very diminutive piece broke into two unmanageable portions in the attempt to bore through it for the passage of the silver wire. M. Berger very ingeniously surmounted the difficulty by encircling the patella with a silver wire, which, after traversing the triceps tendon, at the level of its insertion into the bone, was taken along the sides of the bone and finally brought to the point of departure after having transfixed the ligamentum patellæ. The periosteum and the skin wound were then sutured, and the limb fixed in a gypsum apparatus. The results were admirable, all the joint movements being perfect and the union all that could be desired.

#### *The Cholera in France.*

The cholera epidemic appears to be making no further progress in the suburbs situated to the north of Paris. At Clichy blocks of buildings, which sheltered about 300

families of ragpickers have been condemned on account of their insanitary state and the wretched denizens have been promptly evicted. The brothers Rothschild have, with characteristic kindness, forwarded a sum of 5000 francs to be distributed amongst these victims of sanitation. The epidemic at the lunatic asylum of Bonneval, in the Department of Eure-et-Loir, which broke out on the 17th ult., is almost extinct. It is a curious fact that, although the male and female inmates lived under identical hygienic conditions, only the women were attacked, every man escaping. In the first few days of the outbreak the symptoms were exceedingly violent, and were sudden in their invasion. They consisted of nausea and vomiting, colics, pains in the extremities, with cramps, pale, profuse and involuntary stools. Then came algidity with blueness, slight œdema of the extremities, and an imperceptible radial pulse. From the very onset the features were drawn and the choleraic physiognomy was quite characteristic. A fatal result ensued in from twenty-five to thirty-six hours—sometimes in twelve or fifteen hours, in one instance in only four hours and a half. In a few days after the beginning of the outbreak the disease assumed a milder type, and recovery or death took place after some days of illness. Up to Saturday last the number of inmates attacked was forty-one, no less than twenty of these succumbing. Cases as they occurred were promptly isolated in a special building and every drop of water consumed or used for toilet or domestic purposes was previously boiled. As your readers know, Seine water has been very generally held responsible for the epidemic which has been creating such havoc since April in the suburbs of Paris. The following facts lend support to this theory. The faubourg of Mazagrán is situated partly in the town of Argenteuil, partly in the village of Sannois. The houses touch, all the inhabitants belong to the working classes and the sanitation is equally bad in all the habitations. On the Argenteuil side, the Mazagránais are supplied with Seine water, whilst the people living at the other, or Sannois end, drink only water derived from the River Oise. Amongst the first class numerous (and often fatal) cases of cholera have occurred, while the people who drink Oise water have hitherto remained immune.

Paris, Aug. 3rd.

## BERLIN.

(FROM OUR OWN CORRESPONDENT.)

### *The Cholera.*

THE Prussian Ministry of Ecclesiastical, Educational and Medical Affairs has caused the following statement to be published in the papers of what it is most necessary for all and sundry to know regarding cholera, an example well worthy of imitation by all similar authorities throughout the world: "1. The virus of cholera is in the evacuations of the patients, and can be transferred with them to and into other persons and in the most various things with them and be carried about. Such things are, for instance, linen, clothes, articles of food, water, milk and other drinks; and with all of them, even if only the slightest traces of the evacuations, not perceptible to the natural senses, exist on or in them, the pestilence can spread. 2. It easily happens, therefore, that the contagion is carried from place to place by persons who are or have been ill of cholera or have come into contact with such, and who leave their places of residence in order, as they think, to escape the danger that threatens them there. This is all the more to be warned against, as, on the one hand, one may be already infected before departure, and, on the other, one can protect oneself better at home than elsewhere, especially when travelling, by taking the following precautions. 3. People should not be received into houses from places where cholera exists. As soon as cases of cholera have occurred in a place, persons coming from it must be regarded as possible bearers of the germ of the disease. 4. Lead as regular a life as possible. Experience teaches that all disturbances of digestion make one specially susceptible to cholera. Be on guard, therefore, against whatever can produce such disturbances, such as excessive eating and drinking and indigestible foods. Avoid especially whatever causes diarrhoea or irritates the stomach. In case of diarrhoea, however, consult a doctor at once. 5. Eat and drink nothing coming from a house where cholera is present. Things by which the disease can easily be transmitted—for instance, fruit, vegetables, milk, butter, fresh cheese—must be avoided or taken only after being boiled. Especially the drinking of

unboiled milk is to be avoided. 6. All water which may be polluted by excrement, urine, kitchen refuse, or other dirt must be most rigorously avoided. Water taken from the ground under inhabited places, or from swamps, ponds, drains or rivers, is suspicious, because impurities generally flow into them. Water polluted in any way by the excrements of cholera patients is especially dangerous. Special care must be taken that water that has been used in cleaning vessels or dirty linen does not get into or even near wells or standing and running waters. The best protection against the pollution of well water is afforded by iron tube wells driven straight and sufficiently deep into the earth (Abyssinian wells). 7. If it is impossible to get free from suspicious water, it must be boiled, and only boiled water drunk. 8. All this applies not to drinking water alone, but also to all water used for domestic purposes, because germs of disease can be communicated to the body by water used in cleansing kitchen utensils, cleansing and cooking food, washing, bathing, &c. In general, the belief that drinking water alone is to be regarded as the bearer of the virus and that one is completely protected if only unexceptionable water is drunk, is urgently to be warned against. 9. Every cholera patient may become the starting-point for the further spread of the disease, and it is therefore advisable to send such patients to hospitals. If this is impossible, nobody must be permitted to approach them without necessity. 10. Never enter a house with cholera in it except at the call of duty. Never visit places where many people are assembled in cholera times. 11. Never eat, drink, or smoke (even for one's own sake) in rooms in which there are cholera patients. 12. As the evacuations of cholera patients are specially dangerous, clothes and linen soiled with them must either be burned at once or disinfected in the manner stated in the instructions for disinfection published simultaneously with this. 13. The most scrupulous care must be taken that cholera evacuations do not get near wells or rivers serving as sources of water-supply. 14. All articles coming into contact with patients which cannot be destroyed or disinfected must be rendered harmless by means of hot vapours in special disinfecting establishments or not used for at least six days, during which they are kept in a dry and airy place exposed as much as possible to the sun. 15. Persons who come into contact with a cholera patient or with his bed or clothing should wash their hands at once, especially if soiled with the excrement of the patient. Do not touch food with unwashed hands or put into the mouth eating and drinking utensils, cigars, or anything else that may have been soiled in the sick room. 16. In case of death the corpse must be removed to a mortuary as soon as possible. If it cannot be washed there it ought not to be washed at all. The funeral should be as simple as possible. The guests should not enter the house of death or take part in any funeral feast. 17. Articles of dress, linen and other things that have been used by cholera patients or been in contact with the corpses of such patients must on no account be used or given to others till they are disinfected. Especially they must not be sent to other places unless disinfected. The receivers of packages containing such articles from cholera places are urgently advised to send them at once, if possible, to a disinfecting establishment, or to disinfect them themselves with the necessary precautions. Cholera linen ought not to be received for cleaning till it has been disinfected. 18. No other preservatives against cholera are known, and the public are advised not to use the medicaments—cholera-brandy &c.—which are always puffed in cholera times."

Berlin, Aug. 2nd.

## Obituary.

W. F. CUMMING, M.D. EDIN.

A TYPICAL specimen of the accomplished physician has just passed away in the octogenarian Dr. Cumming, who died on Wednesday, July 27th, at Loch Baa, Mull, Argyshire. A cadet of the clan Cumming of Altyre, he was born on the banks of the Findhorn on Oct. 26th, 1805, and like his two brothers—one of whom was a distinguished colonel of the 21st Fusiliers and the other an able and much-employed surgeon—he was destined to make his mark in the world. He

studied medicine at the Edinburgh School, graduated as doctor and shortly thereafter entered the medical department of the East India Company's service. His health, at no time robust, declined in the tropical climate. He came back to Scotland, and in 1836, after consultation with his professional friends, set out on a prolonged tour which included Italy, Greece and the Ottoman Empire as far as Egypt. A record of his travels is embodied in his once popular and even now eminently readable "Notes of a Wanderer in Search of Health," of which the first volume was inscribed to his chief, Sir W. G. G. Cumming, Bart., of Altyre, and the second to his accomplished fellow traveller, V. F. Campbell, Esq., of Islay. The book, which teems with a racy sagacity characteristic of the author, is notable for its anticipation of the now general opinion as to the value of Egypt as a resort in chest disease, from which he himself was a sufferer. Coupled with this shrewd appreciation of the steady, dry, pure, restorative air of the desert was his not less emphatic recommendation to study prudence under medical advice—the two conditions of real and lasting benefit derivable from any climate whatever. He was in himself a striking confirmation of the soundness of this rule, and, though more than half an invalid till long past middle life, he kept himself in health of body and mind sufficient for all the requirements of a physically and mentally active life. Later in his career he visited Germany and Belgium and—always a keen observer—he made their lunatic asylums an object of special study. His experience fructified in a work of high merit entitled "Notes on Lunatic Asylums in Germany and other parts of Europe"—a work which contributed effectively to the introduction of the non-restraint system now so largely and so profitably practised at home and abroad in the treatment of the insane. Dr. Cumming's connexion with the Argyll family led to his acting as body physician and as travelling companion to the Marquis of Lorne (the present duke)—a post which none could have filled better than he, having regard to the cultured and refined tastes which he divided with his accomplished pupil. The friendship then formed and cemented drew still closer the intimacy between them, and when the duke became Lord Privy Seal in the Earl of Aberdeen's cabinet Dr. Cumming was made his private secretary, a post he again took when his Grace accepted office under Lord Palmerston. Not long after the second of these appointments the doctor, who was a keen angler, paid the penalty of his enthusiasm by contracting a paralytic affection of the lower extremities due to prolonged exposure in an open boat to cold and wet. This he never got over; but he did not allow it to lessen his indulgence in sport. In his summer quarters on Loch Baa, Mull, from the door of his lodge to the shore of the loch, he had a tramway constructed, and along this he was conveyed in a basket-carriage, from which he was easily transferred to a boat in which he landed quite as many salmon as in his prime. With all this passion for open-air life he was a reading man of fine taste and exemplary assiduity, his favourite authors being Milton and Johnson among the English and Burns and Scott among his compatriots. "He never passed the Scott monument in Prince's-street," writes one who knew him well, "without lifting his hat and insisting that anyone with him in the carriage should pay the same homage to the Wizard of the North." His independence in matters of opinion political and religious made him indifferent, as Byron says in "Don Juan":

"To Trojan or to Tyrian,  
And, like his sires, a moderate Presbyterian."

For his *alma mater* he retained to the last an overflowing affection—appropriately typified in his donation of the fountain which adorns the University quadrangle. For many years he was the guest of his sister Lady Coxe (wife of Sir James Coxe, the accomplished Commissioner in Lunacy for Scotland) whose beautiful residence at Kinellan he occupied after their death, making it in turn the scene of much kindly and cultured and highly appreciated hospitality. To the last he took a lively interest in political contests, in the Midlothian election of 1880 being "lifted from his carriage into a basket-chair, which was wheeled into the polling station. But," adds the friend to whom we are indebted for most of the above details, "the chair could not be got into the polling booth." In this dilemma an appeal was made to the polling sheriff, who, at his wit's end to meet a contingency not provided for under the Ballot Act, yielded at last to the doctor's insistence and had a ballot-paper brought out to him. The doctor then made his "X" on the crown of his hat.

He was never married, and his lovely suburban residence at Kinellan passes into the possession of Sir J. Coxe's daughter, Mrs. Rose-Innes. Dr. Cumming's funeral, starting from Kinellan, took place at Edinburgh on Tuesday, August 2nd, and was attended with every mark of respect by a large number of professional friends and of the general public.

## THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

At an ordinary meeting of the Council of the Royal College of Surgeons, held on Monday, the 1st inst., the minutes of the quarterly meeting of the Council held on July 14th were read and confirmed.

The Secretary reported the death on July 19th of Mr. Frederick Le Gros Clark, F.R.S., past president, past member of the Council and of the Court of Examiners of the College. A resolution of condolence was unanimously passed and directed to be sent to Mrs. Clark and the family on their sad loss.

The museum and library will be closed as usual during the month of September for the purpose of a general cleaning.

Sir W. Mac Cormac was re-elected a member of the Court of Examiners in Surgery and Mr. J. C. N. Davies-Colley was elected an Examiner in Surgery in the vacancy caused by the retirement of Mr. Bryant.

Dr. H. J. Campbell was elected a Professor of Comparative Anatomy and Physiology in the vacancy left over from the last meeting. A letter from Dr. Liveing reporting the proceedings of the Royal College of Physicians on July 28th was received and read.

It was agreed that the annual meeting of Fellows and Members of the College should be held on Thursday, Nov. 3rd, at 3 P.M., and that the usual notices should be issued.

A committee was then appointed to consider and report on the standing rules and to submit a revised copy to the Council; also to consider any resolution of the Council at present extant on the proceedings of the Council. The members of this committee are the President and Vice-Presidents, Messrs. Macnamara, Rivington and Tweedy.

Mr. Macnamara moved, and Mr. Langton seconded, the following resolution, which was agreed to:—"That it be referred to the Nomination Committee to consider and report to the Council whether any, and if so what, alterations are desirable in the arrangements for the museum and other lectures." The next meeting of the Council will be held on Thursday, October 13th.

## Medical News.

**EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.**—The following gentlemen, having passed the necessary examinations, have been admitted by the two Royal Colleges Diplomates in Public Health:—

Armin, Henry Charles Laffler, L.R.C.P., M.R.C.S., Surgeon Captain  
Indian Medical Staff (Charing-cross), Hyde-street, W.  
Bailey, W. Henry, M.B. Lond., M.R.C.S. (St. Barth.), East Dulwich.  
Best, William Jenner, M.R.C.S. (London), Louth, Lincolnshire.  
Coates, Henry Honiton, L.R.C.P., M.R.C.S. (St. Barth.), Soho sq., W.  
Gay, John, L.R.C.P., M.R.C.S. (St. Barth. and King's Coll.), Putney.  
Gibson, James Hill, M.D. O.U.I. (Dublin and Belfast), Maiden-vale.  
Hall, John Moore, M.B. R.U.I. (Belfast and King's), Old Ford road.  
Hoyle, James Collings, L.R.C.P., M.R.C.S. (St. George's), Homerton.  
Mann, Harold Edward, L.R.C.P., M.R.C.S. (St. Barth.), Homerton.  
Orr, William Young, M.B. Edin. (Edinb. and King's), Putney.  
Preston, George, L.R.C.P., M.R.C.S. (Manchester), Saltash, Cornwall.  
Priest, James Damer, M.R.C.S. (St. Barth.), Waltham Abbey.  
Ricketts, Thomas Frank, L.R.C.P., M.R.C.S. (Guy's), Cheltenham.  
Schorstein, G. Isidore, M.B. Oxon. (Oxford and Lond.), Portland-pl.  
Scott, Sack Roy, L.R.C.P., M.R.C.S. (Charing-cross), Lushington.  
Tratman, Frank, M.B. Lond., L.R.C.P., M.R.C.S. (Lond. and Bristol),  
Bristol.  
Wilkie, John, M.B. Lond. (Univ. Coll. and St. Barth.), Buckingham-  
street, Adelphi.

Eight candidates were referred.

**ROYAL COLLEGE OF SURGEONS OF ENGLAND.**—The following gentleman, having previously passed the necessary

examinations and having now attained the legal age (twenty-five years), has been admitted a Fellow of the College:—

Drew, Douglas, M.B., L.R.C.P. Lond., Gloucester-place, W.; diploma of Member dated July 28th, 1890.

The following Licentiate of the Royal College of Physicians of London, having previously passed the necessary examinations and having conformed to the by-laws and regulations, have been admitted Members of the College:—

All, Subban, Islington.  
 Acherley, John, Leeds.  
 Baker, J. Charles, Kentish Town.  
 Ballance, H. Ashley, Hampstead.  
 Banham, C.W.R., Snifron Walden.  
 Barnes, H. Cooper, Philpot-street.  
 \*Blake, H. Elliot, Guy's Hospital.  
 Bliss, E. W., Brerley Hill, Staffs.  
 Bond, W. Ernest, Little Britain.  
 Bowie, R. Arthur, Store-street.  
 Brimacombe, R. Wm., Worcester.  
 Brown, H. Corser, Tipton, Staffs.  
 Bull, Stanley Arthur, Kensington.  
 Bunch, F. V., Gloucester crescent.  
 Buttar, Charles, Stratford-place.  
 Carwardine, Thomas, Willesden.  
 Cazale, Grenville W., Guilford-st.  
 Charles, B., South Hampstead.  
 Cross, Geoffrey, Brixton.  
 Cutcliffe, M., Witheridge, Devon.  
 Darker, Geo. F., St. George's-sq.  
 Davies, Richard, Hereford.  
 Dixon, Charles Arthur, Leeds.  
 Dove, Frank, Colchester.  
 Dunderdale, R. H. W., Blackpool.  
 Eames, E. T. Philip, St. Johns.  
 Edwards, Frederic W., Forest Hill.  
 Fowler, Jas. Stewart, Edinburg.  
 Fraser, Herbert St. John, Sutton, Surrey.  
 French, H. C., Shoeburyness.  
 Fyfe, Reginald J., Forest Hill.  
 Gaskell, Arthur, Dartmouth.  
 Gedgo, A. Syd., South Clapham.  
 Girdlestone, Howard E., Brixton.  
 Gladstone, R. J., Old Aberdon.  
 Goodwin, T. H. J. C., Paddington.  
 Graydon, A., Philbeach-gardens.  
 Griffiths, R. C., Upper Woburn-pl.  
 Griffiths, S. A. R., Corinne-road.  
 Hague, John, Ashton-under-Lyne.  
 Hainworth, E. M., Blackheath.  
 Hamlen-Williams, T. R., London.  
 Harris, Frank Drew, Clapham.  
 Hartnell, E. Bush, Borough.  
 Harvey, J. Harold, Little Haven, Pembroskshire.  
 Heath, Arthur Douglas, Exeter.  
 Hemsted, E. Spencer, Whitchurch, Hants.  
 Henry, Robert, Putney.  
 Hepburn, M. L., New Kent-road.  
 Hessey, Jas. D., Mornington-pl.  
 Hogg, R. H., Albert-street, N.W.  
 Jaffé, C. S., Westbourne-terrace.  
 James, R. B., Stratford-on-Avon.  
 Jenkins, John E. M., Wimbledon.  
 Jones, John, Mornington-cresc.  
 Kent, Sydney, Sevenoaks.  
 Killery, St. John B., Chiswick.  
 Knapp, M. Henry, Paddington.  
 Langford, Morris Chas., Padstow, Cornwall.  
 Lightfoot, J. Parker, Brixton.  
 Loos, W. Chris., Upper Norwood.  
 McCormack, C. Vincent, Liverpool.  
 Mackeson, Guy, Courthope-rd.  
 Milnor, A. E., Lansdown-place.  
 Milton, A. R. Octavius, Lambeth.  
 Morley, G. Frederic, Sinclair-rd.  
 Morton, J. Leyden, Kilburn.  
 Musgrave, C. B. T., Notting-hill.  
 Nellen, G. F. Marshall, Brighton.

Newton, H. W., West Hampstead.  
 Nicol, James Main, Leeds.  
 Ortlepp, Albert J., Harrow-rd.  
 Osborn, Francis A., Falmouth-rod.  
 \*Parker, William, Holloway.  
 Parrott, Albert Geo., Chingford.  
 Perry, S. Herbert, Frederick-st.  
 Perry, W. Arthur, Bournemou-th.  
 Pethybridge, W. Ley, Plymouth.  
 Pickering, R. Neville, Lewisham, Upper Berkeley-st.  
 Posnett, Edward, Leeds.  
 Potter, Walter, York.  
 Powell, W. A., Batterssea Rise.  
 Randall, Martin, Hendon.  
 Ransome, H. F., Altrincham.  
 Renny, Eustace Geo., Pimlico.  
 Rock, Cecil Howard, Lewisham.  
 Russell, J. Ronaldson, Dartford.  
 Savers, J. Lorimer, Blackheath.  
 Shearer, J. Geritt, Highbury-park.  
 Scotson, Fredk. C., Warrington.  
 Selby, E. W., Albert-street, N.W.  
 Selby, William, Croydon.  
 Shaw, A. Band, Wandswoth.  
 Sims, J. Hadley, Osborn-terrace.  
 Smith, Edwin, Wandswoth.  
 Smith, Norman Ireland, Windsor.  
 Smith, Wm. Robt., King's College Hospital.  
 Spencer, Chas. Geo., Norland-sq.  
 Spront, Jas. Hugh, Birmingham.  
 Squibbs, R. E. P., Albert-street.  
 Staddon, Henry Ernest, Ipswich.  
 Steggall, S. L. J., Queen-square.  
 Stewart, Jas. Allan, Notting-hill.  
 Strange, A., Knebwoth, Herts.  
 Sutcliffe, Wm. G., Larkhall-lane.  
 Swabey, Maurice, Bath.  
 Sylvester, H. Mayris, Caroline-place, W.C.  
 Templeton, George, Kilmarnock.  
 Thomas, R. S., Starcross, Devon.  
 Tipping, Henry Hubert, Alcester, Warwickshire.  
 Toller, Neville Percy F., Lambeth.  
 Tweedy, R. C., Redruth, Cornwall.  
 Vincent, Wm. James Nathaniel, Newcastle-on-Tyne.  
 Vinaco, M. H., Birmingham.  
 Wall, Frank, Totteridge.  
 Walter, E. Arthur, Woburn-sq.  
 Walters, A. Radclyffe, Reigate.  
 Walters, F. Wilfred, Sydenham.  
 Watkins, W., Turner-st., Mile End.  
 Wesley, F. W., Burlington House.  
 West, W. Goldsborough, Thaxted.  
 Wheatcroft, E. Woodiwiss, Derby.  
 White, Jas. A. H., Birmingham.  
 Williams, George C. Waldemar, Peckham.  
 Williams, H. J. E. Hutchins, Lee.  
 Williams, Herbert Whitley Skey, Holywell, North Wales.  
 Wilcock, E. Hulse, Norwood.  
 Willson, J. Wherry, Bernard-st.  
 Windsor, Frank N., Manchester.  
 Winter, Laurence A., Woodford.  
 Withers, F. Ernest, Reading.  
 Wright, S. F., Bickley, Kent.  
 Wroughton, Wm. Chas. Haulton, Highbury-hill.  
 Wysard, Alex. T., Denmark-hill.

The following gentlemen have also been admitted Members:—

\*Austin, J. H. E., L.R.C.P. Edin., Chiswick.  
 \*Council, Richard Watson, L.S.A., Lorrimore-square.  
 \*Hancock, H. R., L.R.C.P. Irel., Burslem, Staffordshire.  
 \*Hawley, Frederic Hulme, L.S.A., Timberland, Lincolnshire.

\*Miche, W. A., M.B., C.M. Aberd., Greenwich.  
 \*Soden, T. Armand Bourne, L.S.A., Newcastle-on-Tyne.  
 \*Soilloux, Garnet, M.B. Moll., Clements-lane.  
 \*Young, John C., M.D. New York, Bernard-street.

\* Candidates who have not presented themselves under the Regulations of the Examining Board in England.

**VICTORIA UNIVERSITY.**—The degrees of M.B. and Ch.B. were conferred by the Vice-Chancellor of the Victoria University at Owens College on July 30th:—

*First Class Honours:* J. H. Crocker, Owens. *Second Class Honours:* C. R. Marshall, Owens. *Pass, First Class:* J. C. Buckley and F. J. H. Coultis, Owens; W. E. Davies, University; A. Greenhalgh, Owens; W. M'Lolland and J. B. Mawdsley, University; Alfred Murgatroyd, Owens; A. J. Partridge, University; O. H. G. Ramsbottom, Gruner Stowell, W. H. Waddington, and W. A. Williamson, Owens.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.**—At the July sittings of the above Conjoint Board the following candidates passed the Final Examination:—

Janet M. C. Gray, London; John C. Edwards, Oswestry; Joseph M. Roche, Liverpool; Hugh N. A. Taylor, B.A., Cambridge; Daniel MacCarthy, Cork; Robert A. Potterton, Dublin; Jas. G. Willis, Portarlinton; William P. Willis, Shettleston; Geo. Ellis, Ossett; John James Brennan, Kilkenny; William R. Thrower, London; Henry C. Darby, Stourbridge; James P. T. Burke, Thurles; Cuthbert Rutherford, Glasgow; Alexander Wheeler, Edinburgh; Henry J. Cosgrove, Dumfries; Samuel E. Jones, Mold; Thomas Young, Irvine; Thomas W. Bartlett, London. *Division I.*—W. C. Alexander, C. R. Huxley, *Division II.*—W. Owen, R. T. Clark, W. W. Forrester, W. C. Alexander. *Division III.*—L. Burges, Wm. Owen, C. R. Huxley, A. A. D. Parke.

**UNIVERSITY OF GLASGOW.**—The following gentlemen received the degree of M.D. on July 28th:—

\*Hugh Highet, M.B., C.M.; \*Alexander Glen Park, M.B., C.M.; James Duncan, M.B., C.M.; Peter Fraser, M.B.; Robert Alex. Morton, B.Sc., M.B., C.M.; James Muir, M.B., C.M.; J. F. Muir, M.B., C.M.; John Stewart McConville, M.A., M.B., C.M.; Alex. Shanks, M.B., C.M.; John Pollock Simpson, M.B., C.M.; John Somerville, M.B., C.M.; William Callender Taylor, M.B., C.M.; Andrew Stewart Findlay, M.B., C.M.

\* Received commendation.

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.**—The following have passed the Third Professional Examination:—

G. H. Ayres, Jeremiah Behane, A. C. Callaghan, Henry Carre, W. J. Coneys, L. F. Corbet, J. J. Dolan, C. P. Haman, R. J. Harvey, E. L. Hunt, H. Hunt, P. K. Joyce, H. H. Moffat, C. E. Murphy, H. McDermott, J. G. Lanahan, M. J. O'Brien, W. F. Pigott, T. A. Poitrot, J. H. Power, W. F. Roe, C. R. Rothwell, R. Somerville, H. Sweeney, W. Taylor, Elizabeth A. Tennant, and H. G. Thompson.

**NEW CONVALESCENT HOME.**—Mr. Passmore

Edwards having given a convalescent home to his native county, Cornwall, it was formally opened by Mrs. Edwards on the 1st inst. It is located at Perranporth, about nine miles from Truro, on the north coast and near to Blackwater. The home contains twenty beds for patients. Besides building and furnishing it Mr. Edwards has given £3000 towards its endowment. Mr. Edwards was present, and formally handed it over to the Governor of the Royal Cornwall Infirmary, Truro.

**DEATH UNDER CHLOROFORM.**—An inquest was

held at Uxbridge-road, on the 2nd inst., on the circumstances attending the death of Mr. J. M. M. Bishop, which took place in St. Bartholomew's Hospital whilst undergoing an operation for the removal of a deep-seated abscess of the liver. The deceased was put under the influence of chloroform previously to the surgical procedures, and all went well until the operation had been almost completed, when the respiration suddenly ceased and all the means adopted to restore animation were found unavailing. The jury returned a verdict of "Death by misadventure."

**THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY, LIMITED.**—At a meeting of medical men

residing in the north of London, held at Tottenham on Thursday, June 30th, it was resolved to establish a division of this Society for the north of London. The following officers and council were elected subject to confirmation by the Central Council:—Divisional President: E. Hooper May, M.D., F.R.C.S. Vice-Presidents: D. Fairweather, M.R.C.S.; Frank Godfrey, L.R.C.P., L.R.C.S.; Frank Greaves, M.R.C.S., L.S.A.; G. Greenwood, L.R.C.P., M.R.C.S.; George Henty, M.D.; Charles P. Langford, M.R.C.S., L.S.A.; T. Boswall Watson, M.D.; W. T. Watson, M.D., M.R.C.S. Council: W. B. Benjafield, M.B., C.M.; J. B. Cook, M.R.C.S., L.R.C.P.; James Dawson, M.D., L.R.C.S.; W. Donston, L.D.S., R.C.S.I.; L. Grant, M.D.; Arthur Greenwood, L.R.C.P., M.R.C.S.; James Heath, M.D.; G. T. Penny, M.A., M.D., M.R.C.S.; J. J. Pitcairn, L.R.C.P., M.R.C.S.; G. H. Vos, M.B., M.R.C.S.; A. O. Ward, M.D., M.R.C.S.; E. Wood, L.R.C.P., M.R.C.S. Hon. Secretary: Lloyd G. Smith, M.D., C.M. It was resolved that three ordinary meetings of the Divisional Council should be held each year in the months of January, May and October, and that the annual meeting of the members of the division should be held in June of each year. Instructions were given for the issuing of circulars to all medical men residing in the district, inviting them to join the Society. The secretary was directed to lay the names of all applicants for membership before the Divisional Council previously to their being submitted to the Central Council for election, in order to assure the eligibility of the candidates.

**DR. R. J. WHITE (Brentwood)** has received notice that the Local Government Board have awarded him the Government grant for public vaccination for the third time.

**HOSPITAL FOR THE LUDDENDENFOOT DISTRICT.**—The local boards of Midgley, Luddendenfoot and Warley have agreed to jointly establish a hospital for infectious diseases. Each authority is to contribute to the cost and expenses of the hospital on the basis of the population.

**OPEN SPACES.**—The Trustees of the London Parochial Charities, at their last meeting, resolved to grant £2000 towards the fund for the acquisition of Hackney Marshes, and £1000 to the fund for the acquisition of the Paddington Recreation Ground.

**DR. THOMAS N. BRUSHFIELD** has been elected President of the Devonshire Association for the Advancement of Science, Literature and Art at the annual gathering to take place next year at Torquay. Sir S. Bowring, S. A. Froude, and the Rev. C. Kingsley are in the list of past presidents.

**ST. BARTHOLOMEW'S HOSPITAL.**—On July 28th, at a meeting of the governors of the hospital, at which Mr. Wire presided, the Lord Mayor proposed and Sir William Savory seconded the nomination of Sir Trevor Lawrence as treasurer of the hospital, in the room of Sir Sydney Waterlow, who has retired. There being no opposition, Sir Trevor Lawrence was elected.

**BASINGSTOKE COTTAGE HOSPITAL.**—The thirteenth annual meeting of subscribers to this institution was held in the Town Hall, Basingstoke, the Rev. A. G. Barker, president, being in the chair. The report stated that during the year seventy patients had been treated at the hospital, forty of whom were discharged cured and seventeen more or less improved. The balance-sheet, which was also submitted, showed the income to amount to £441 16s.

**THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN.**—On July 30th the Lady Mayoress handed over to Mr. Edwin Lawrence, the chairman, and Mr. R. G. Kestin the secretary, of the Royal Hospital for Children and Women, Waterloo-bridge-road, a cheque for £1028 9s. 9d., being the net profits from the rose show recently held at the Mansion House in aid of that institution. The committee have presented the Lady Mayoress with an illuminated address of thanks inclosed in a handsome album, and have elected her an honorary life governor of the hospital.

**PRESENTATION.**—A testimonial consisting of a claret jug and spirit stand has been presented to Dr. Robert Jones, medical superintendent of Earlswood Asylum, by the officers and staff "as a token of their admiration of his brave act in saving the life of a little child at the risk of his own." Dr. Jones sucked the tube in a case of tracheotomy for diphtheria in the child of an asylum employé, when an obstruction threatened the death of the patient. This heroic act was happily accomplished without contracting the disease.

**FOOD ADULTERATION IN SHEFFIELD.**—The health department of this borough is taking active steps for the protection of the public against adulteration of food, especially in respect to milk. Last week four milk-sellers were fined, in sums varying from £6 and £1 each and costs, for selling impoverished milk. A farmer was amerced in a penalty of 10s. and costs for want of cleanliness in the cow-shed in which his milk vessels were kept. In two cases for selling butter which contained a large percentage of margarine fines of £1 each and costs were inflicted.

**PUBLIC HOSPITAL AND DISPENSARY, SHEFFIELD.**—The work of this institution during the past year shows a satisfactory increase. The in-patients treated were 51 in excess of the previous twelve months. The expenditure had exceeded the ordinary income by £1058. The capital account had by legacies been increased by £3048 14s. 5d. After deducting the aforesaid deficiency the net increase was reduced to £1990 13s. 7d. The anticipated commencement of the new hospital had been delayed entirely from a desire to comply with the express wish of the corporation; but the difficulties had now been overcome and steps would shortly be taken for building the first block.

**SANITARY INSTITUTE, LONDON.**—The Duchess of Albany distributed, at the Parkes Museum, on Wednesday, the certificates to the ladies who had passed the examination following the lectures delivered at this institute on domestic hygiene. Sir Douglas Galton, the chairman, presented the report of the examiners, which spoke satisfactorily of the work accomplished.

**ANCOATS HOSPITAL, MANCHESTER.**—The annual report for the past year records a steady and increasing interest in the institution on the part of friends and subscribers. The number of beds available have been increased by the opening of No. 5 Ward, which leaves one ward only (the Memorial Ward) empty. This too could be filled, thus utilising the whole of the ward space in the Albert Victor wing, but the state of the funds forbid the committee incurring further expenditure. The small convalescent home at Wilmslow has been a boon to over 100 women patients. The financial statement shows a balance due to the bankers of £690. But the treasurer has received since the accounts were made up, a check for £1000 in memory of the late Mr. Oliver Heywood, and also a check for £1000 from Mr. Jardine.

**PROPOSED NEW INFIRMARY, ISLINGTON.**—On the 28th ult., at a meeting of the Islington guardians, the proposal to acquire a site for a new infirmary for the parish in Tollington-park came up for discussion. The chairman (Mr. J. S. Furlong) said a new infirmary was urgently needed, and the proposed site was a good one. It was objected to on the ground that the property in the neighbourhood would be depreciated, and he explained his reasons for deeming the objection a mistake, adding that in other parts of London such buildings did not damage the neighbourhood. Some discussion ensued, which resulted in a postponement of the further consideration of the question until the committee appointed by the opponents of the scheme could see the plans and lay their views before the board.

## Appointments.

*Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST AND THROAT.—Honorary Assistant Medical Officer.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer, for one year. Salary £150 per annum, with board and residence.

MESSRS. MUNK & ADIE, Solicitors, 27, Clement's-lane, E.C.—Medical Man to act as Director on the Board of a small Provident Company.

MOULSFORD ASYLUM, near Wallingford, Berks.—First Assistant Medical Officer. Salary £130, rising by £10 per annum to £150, with rooms in Asylum, and board.

ROYAL UNITED HOSPITAL, Bath.—Honorary Physician.

STOURPORT MEDICAL AID ASSOCIATION.—A qualified Assistant. Salary £120 per annum (out-door). (Apply to Mr. Bourne, Station House, Stourport.)

STURMINSTER UNION.—Medical Officer and Public Vaccinator for the Hinton District. Salary £40 per annum, with fees for Vaccination; the ordinary Midwifery cases, attended under orders, 10s., and extra medical fees for treatment of fractures &c. (Apply to the Clerk, Poor-law Offices, Sturminster Newton.)

SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds. House Surgeon. Salary £100, with board, lodging and washing.

THORNBURY UNION.—Medical Officer for the Almondsbury District. Salary £70 per annum, with extra fees for midwifery cases, and for the operations and services specified in the Orders of the Local Government Board, and also at per case for public vaccination, under contract. (Address to the Clerk to the Guardians, Thornbury.)

YORK RETREAT.—Senior Assistant Medical Officer. Salary £150 per annum, with board and lodging.

## Births, Marriages, and Deaths.

### BIRTHS.

BEACH.—On July 30th, at Darenth Asylum, Dartford, the wife of Fletcher Beach, M.B., F.R.C.P., of a son.

COPNER.—On July 21st, at Capstone Lodge, Ilfracombe, the wife of Arthur L. Copner, M.R.C.S., of a son.

DAVENPORT.—On June 5th, at Chung-King, W. China, the wife of C. J. Davenport, F.R.C.S., prematurely, of a son, stillborn.

HORDER.—On or about July 28th, at Pak-how, S. China, the wife of Dr. E. G. Horder, C.M.S., of a son.

ORMEROD.—On July 26th, at Greenhill, Bishop's Waltham, the wife of Joseph Arderne Ormerod, M.D. Oxon., F.R.C.P. Lond., of a son.

ROCKLIFFE.—On Aug. 2nd, at 9, Charlotte-street, Hull, the wife of William Craven Rockliffe, M.A., M.D., of a daughter.

STONE.—On July 25th, at Sandfield, Belgate, the wife of Dr. Stone, of a daughter.

VACHER.—On July 28th, at Glamford, Birkenhead, the wife of Francis Vacher, late Medical Officer of Health, Birkenhead, of a son.

WESTON.—On July 31st, at Groveley House, Handsworth, the wife of S. T. Darby Weston, of a son.

WOMACK.—On July 30th, at Dennington-park-road, West Hampstead, the wife of Fredk. Womack, M.B., of a son.

### MARRIAGES.

BATTERHAM—CAMPBELL.—On July 23th, at All Souls', Clive Vale, Hastings, John Williams Batterham, M.B., F.R.C.S., to Mabel Caroline, only daughter of the late Bruce Campbell, Esq., of the Inner Temple, Barrister-at-law.

BIDEN—GRUMMANT.—On July 30th, at St. Saviour's, Denmark-park, S.E., George Henry Biden, L.R.C.P. Lond., of Plas-y-n-dre, Newtown, Monk., to Kate Sarah, youngest daughter of John Grummant, of Bavens, Champion-hill, S.E.

BOOTH—SHAW.—On July 28th, at the Parish Church of St. John's, Pinner, Middlesex, by the Rev. Marcus Rainsford, James Mackenzie Booth, M.A., M.D., C.M. Aberd., to Margaret Mackenzie, daughter of the late James Shaw, Esq.

MACKEITH—GADD.—On July 23th, at St. David's Church, Exeter, Alexander Arthur Mackelith, M.B., C.M., of St. Thomas, Exeter, to Alice, eldest daughter of Henry Gadd, J.P., St. David's-hill, Exeter.

MUSPRATT—KNOX.—On Aug. 3rd, at the Church of the Ascension, Balham-hill, Charles Drummond Muspratt, M.D., F.R.C.S., of Bournemouth, to Mabel, daughter of Ralph Henry Knox, C.B., of Trouville-road, Clapham-park.

MOXEY—TYSON.—On Aug. 2nd, at Vienna, near Washington, U.S.A., David Anderson Moxey, M.D., M.E.C.P. Lond., to Anna M. Tyson.

ROBERTS—PARKER.—On July 20th, at Enderby Parish Church, Dr. Hugh Leslie Roberts, of Rodney-street, Liverpool, to Kate A. C. Parker, daughter of the late S. Parker, Esq., Royal Engineer Department of Mandeville, Gosport.

THOMAS—SPENCE.—On July 27th, at Huntly, N.B., by the Rev. Dr. Semple, W. Thelwall Thomas, F.R.C.S., of 75, Rodney-street, Liverpool, to Anabel Roxburgh, youngest daughter of A. Spence, Esq., Huntly.

WAKELAM—LUPTON.—On Wednesday, Aug. 3rd, at St. Peter's Church, Ashton-under-Lyne, by the Rev. J. Gouldie French, M.A., assisted by the Rev. J. M. Muzzell, B.A., Edgar Wakelam, L.R.C.P. &c., Waterhead, Oldham, late of Willenhall, Wolverhampton, to Emma, youngest daughter of James O. Lupton, Esq., of Richmond House, Ashton-under-Lyne.

### DEATHS.

BARRETT.—On Aug. 1st, at Merchiston-place, Edinburgh, William Barrett, M.B., Surgeon-Major, late 71st Regiment, aged 70.

BELL.—On July 28th, suddenly, at Preston, William Howard Bell, M.R.C.S., Surgeon-Captain in the Army Medical Staff, aged 31.

BELLEW.—On July 20th, at his residence, Farnham Royal, Bucks, Henry Walter Bell, Surgeon-General, C.S.I., C.I.E., aged 57.

BENNETT.—On July 20th, at Longford, Surgeon-Captain William Halloran Bennett, M.B., Army Medical Staff, second son of the late Major-General R. Bennett.

CUMMING.—On July 27th, at Benmore Lodge, Mull, William Fullarton Cumming, M.D. (Logie, Morayshire), of Kinellan, Murrayfield, Edinburgh, aged 87.

FORBES-WATSON.—On July 29th, at Belvedere-road, Upper Norwood, John Forbes-Watson, M.A., M.D., LL.D., late Reporter on the Products of India to the Secretary of State for India and Director of the India Museum, aged 65.

LANE.—On Aug. 2nd, at St. Mary's, Madoley-road, Ealing, Samuel Armstrong Lano, F.R.C.S., in his 91st year.

SOUTER.—On July 28th, at Cumberland-terrace, Finsbury-park, N., Mansfield Collier Souter, M.R.C.S., A.K.C. Lond., aged 48.

VASEY.—On July 31st, at Cambridge-gardens, North Kensington, Chas. Vasey, L.F.P.S., L.D.S. R.C.S. Eng., Consulting Dental Surgeon of St. George's Hospital, in his 70th year.

### IN MEMORIAM.

In loving memory of Edmund Overman Day, M.R.C.S., L.S.A., who was suddenly called to his rest on the 4th August, 1891, interred at Flamstead, Herts, on Aug. 10th, 1891, and reinterred at Norwood Cemetery on the 6th July, 1892.

N.B.—A fee of 6s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Leotures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### THE STUDENTS' NUMBER.

WE beg to call the attention of the Deans of Medical Schools and the Secretaries of Hospitals to the announcement that the Students' Number of THE LANCET for the session 1892-93 will be published on Saturday, Sept. 3rd. We also invite from them and from the members of the profession information regarding hospitals, institutions for medical education &c.—such particulars as are of importance to students generally, both in connexion with the general medical qualifications, the dental qualifications, and the qualifications in public health. This should be sent to the Sub-editor, THE LANCET Office, Strand, not later than the 25th inst.

### THE FRENCH HOSPITALS AND THE TAX ON BETTING.

THE only form of betting sanctioned on French racecourses is that of the *pari-mutuel*. This form of betting is organised by agencies duly recognised by the police. The speculator purchases a ticket indicating the horse he has backed. If the horse wins, the money placed on other horses is given over to the winner, with a deduction, however, of 7 per cent. Two per cent. is kept by the agent as his commission for organising the *pari-mutuel* and the remaining 5 per cent. is handed over to the Assistance Publique—that is to say, the Government administration for the relief of the poor. By this means, out of the pleasures (perhaps we should add the follies) of the public, a considerable sum has been obtained for the promotion of useful or charitable works. Recently a sum of £39,160 has been distributed, which was thus derived from the *pari-mutuel*. It may be of interest to mention what institutions profited from this tax on betting. This is the list:—For the Released Prisoners' Help Society and the creation of an asylum, 24,000 fr.; for a *crèche* in the Rue de l'Ouest, 4000 fr.; for the assistance of the poor and the creation of a workshop for the unemployed of the Batignolles district, 15,000 fr.; for female prisoners and children morally abandoned, 40,000 fr.; for a workshop to train apprentices at Tracy (Oise), 10,000 fr.; to help workmen and create a workshop in the Sixth District of Paris, 10,000 fr.; to the free fund for the purchase of workmen's tools, 3000 fr.; to the building of a new pavilion for the Maternity of Rueil, 50,000 fr.; and to the Society for the Assistance of the Blind, 400,000 fr. The above are, it will be seen, Parisian institutions. The blind come in for the largest share (£10,000), and a lying-in hospital gets £2000. A much larger share of the money given in the provinces goes to purely medical institutions. For the hospitals of Montbelliard and La Force (Dordogne), 50,000 fr.; for the new hospital at Bagnières de Luchon in the Garonne, 100,000 fr.; for the Hospital of Pour-le-Pin in Isère, 40,000 fr.; for the Rouen Asylum, 12,000 fr.; for the d'Aumale Asylum in the Seine Inférieure, 15,000 fr.; for the Labour Assistance Society of Lyons, 50,000 fr.; for the Nérat Asylum in the Lot et Garonne, 6000 fr.; for the poor of the town

of Chaulonay, 15,000 fr.; and for the Maritime Hospital of Pen Bron, Loire Inférieure, 40,000 fr. These gifts, with one or two other items, make a total of 978,500 fr., or nearly £40,000. But there is still more money in hand. There is the question of creating on the shores of the Mediterranean a hospital where the scrofulous children from Paris may enjoy seaside treatment during the winter months. The decision as to what should be given for this purpose has been postponed. Considering the mischief that results from excessive betting on English racecourses many persons will be tempted to inquire whether, as we have frequently suggested, some means could not be devised by which this evil could be turned to the advantage of hospitals and similar institutions.

C. W.—Our correspondent's question is not a medical one and we are unable to reply to it. He had better inquire of the clerk to the authority.

### SMALL-POX AND CHICKEN-POX.

*To the Editors of THE LANCET.*

SIRS,—The cases of small-pox at Saffron Walden bring to my recollection a somewhat similar occurrence when I was practising many years ago in the country. I was sent for late one evening to see the son (aged seventeen) of a farmer, about four miles from my residence. I found him suffering from a well-marked eruption of what I considered to be "chicken-pox." Just as I was leaving the house I accidentally discovered that he had returned from London that day, where he had been a clerk in a large establishment for about three weeks. As small-pox was then very prevalent in London I immediately corrected my diagnosis and on inquiry as to vaccination I found that none of the children—five in number—had ever been vaccinated, as the father had a rooted objection to vaccination. Fortunately I had two tubes of vaccine in my pocket-case and I quickly vaccinated every person in the house. (It may be worth mentioning that to eke out the vaccine I mixed it with a little glycerine.) The wrath of the father on his return home was great, and I was duly threatened with all sorts of legal horrors. The poor boy had a severe attack of confluent small-pox and succumbed on the eighth day. A small panic took place in the village, the house being situated in the very middle of the one street, and it was difficult to get proper help, but I proposed to revaccinate the six bearers engaged to carry the coffin to the church, about a hundred yards from the house. All but one consented and, singular to state, this man contracted the disease in a mild form. The rush of villagers after this to be revaccinated was startling and reminded me of my grandfather's days, when the votaries of venesection waited in a row outside the surgery door for their annual "blood-letting," a custom, by the bye, sadly abused, but one that in some cases might well be employed even in the present day. Exactly a fortnight after the burial of the boy, the father, who had attended the market at the neighbouring town on the previous day, and was noticed then to be in a "queer state," was seized with the complaint in its most malignant form and died from variola hæmorrhagica after forty-eight hours' illness in a comatose state. He was a man of enormous size, weighing over eighteen stone, a free liver and a spirit drinker, and I had literally to roll him from the bed into the coffin, no one save the nurse (who was pitted with small-pox) daring to touch him. It was not a pleasant office. No other case of small-pox occurred. All this happened before the laws of sanitation existed, but I have thought it worth recording.

I am, Sirs, yours faithfully,

London, July 23rd, 1892.

B.

### "BIRTH OF A CHILD WEIGHING FOURTEEN POUNDS."

*To the Editors of THE LANCET.*

SIRS,—A similar case to the one recorded in last week's issue of THE LANCET under the above heading has recently occurred in my own practice. The patient was well known to me and nothing unusual was noticed during pregnancy. She was confined within a few days of the expected date (June 10th), the labour being perfectly normal in every respect. The child (a girl) appeared of excessive size and weight. I did not take any measurements. The weight reached thirteen pounds and a half. The mother and child have progressed excellently. I may add that previous children have been unusually large. Another case, occurring on June 24th, is worthy of remark. The child three days after birth weighed twelve pounds—normal labour and recovery.

I am, Sirs, yours faithfully,

Bexhill-on-Sea, Sussex, July, 1892.

RICHARD WATTS WHITE.

### MICROSCOPY: SARCINÆ.

*To the Editors of THE LANCET.*

SIRS,—Would some microscopist give me a few directions how to mount "sarcina" as a permanent preparation for the microscope. I have tried mounting them in Canada balsam, but they shrivel up; then a coll was made with dammar varnish and filled with Boate's syrup and glycerine, the sarcina mixed and, when the cover-glass was put on, edged round with Holler's glue. Here, again, their contour was broken up. Finding all my efforts fruitless, some were tried in an ordinary glass cell, but again they were all spoiled. It is stated that they can be stained with fuchsin, but I cannot succeed with the red. They would be very beautiful if stained. Any suggestion will be a great favour.

I am, Sirs, yours faithfully,

July, 1892.

A NOVICE.

## QUARANTINE A CENTURY AGO.

AMONG the terrors of the deep enumerated by Horace in his famous address to the ship which conveyed his friend Virgil to Athens quarantine has no place any more than sea-sickness. We know that the latter was familiar to seafaring antiquity, while the former existed, if at all, only in an occasional and arbitrary guise and was enforced against other visitations than those of disease. But practised as it was down to the most recent date, not only on ships of great tonnage, but on the small coasting craft peculiar to Mediterranean waters, it was found to be vexatious in the last degree. A light fishing smack, for instance, the *San Nicolò*, hailing from Hydra, one of the Cyclades, Zuanne Mechze, master, on its way from Naples to the Romanian coast, underwent in 1793 a quarantine of four months and ten days' duration off the island of Poveglia in the Adriatic. During that time ten of its crew died of *pestis bubonica*, but its cargo, consisting of nine thousand cheeses, was unloaded immediately and conveyed to the neighbouring Venice without the diffusion in the city of contagion of any kind. The date, 1793, is noteworthy; for not long after, and certainly during the nineteenth century up to its last decade, quarantine was enforced on cargo as well as on crew, to the very serious prejudice of commercial interests. In fact, in the decennium 1876-85 Italian trade was paralysed, and that country is now congratulating herself on the "Ordinanza," whereby, even in presence of cholera, the restrictions on the unloading of cargo are minimised—reduced, in fact, to little more than a medical inspection, followed, if need be, by disinfection. For this happy change the *Opinione* thanks the Sanitary Congress lately held at Venice.

## "FRIENDLY MEDICAL AID SOCIETIES."

To the Editors of THE LANCET.

SIRS,—Allow me to contribute a page from the life history of a very dear friend of mine, who, like some of your correspondents, held a somewhat erroneous view as to the incompatibility of holding an appointment under a friendly society and a due regard for the "dignity of the profession." In July, 1852, he passed his finals and left his *alma mater*, having graduated with honours. With a view to getting a good insight into general practice, he engaged as an in-door assistant at £70 a year to one of the largest firms of general practitioners in —shire. In a few months he was put in charge of a branch practice at a distance of nine miles from town. In two years' time he had worked it up from £150 a year to £350, when it was sold from under him and he was politely discharged. At this time he had some thoughts of applying for an appointment under a friendly society in the adjacent town of —, but was persuaded that such an engagement would be *infra dig.* In 1855 he obtained an out-door assistantship in the south of England at £140 and an unfurnished house. He married and spent his little savings in furnishing the house, only to hear in six months' time that he must make way for the nephew of his principal, who had recently qualified as L.S.A. Selling up his furniture at a loss of £40, he incurred a further expense of £20 in obtaining and removing to a new situation in —, at the magnificent salary of £100 out-doors, plus half midwifery fees. Refurnishing his little cottage with what remained of his slender capital he enjoyed eighteen months' peace and hard work, only to be then told that his principal was about to retire and to sell his practice. Again breaking up his little home, he, with wife and child, had to seek another situation, and eventually found himself the accepted out of fifty-seven candidates for the position of manager of an East-end practice at the salary of £100 a year, out-doors, plus 5 per cent. on all takings. He recently died of acute rheumatism, brought about by exposure to severe weather in the fulfilment of his duty. Who dares to say that the subject of this brief sketch—alas, typical of hundreds of others—would not have acted more wisely in accepting the fair salary offered by the "Friendly Society" than by slaving himself to death in order to enrich the various "principals" whom he served. Sirs, I affirm that so long as qualified assistants are only offered the equivalent wage of a coachman, a third-rate French cook, or a gouty butler, they are perfectly justified in accepting appointments that will at all events ensure them bread and cheese. A young practitioner who has spent his all in obtaining his degrees or diplomas has to choose between perpetual slavery as an assistant (getting possibly 4 or 4½ per cent. on the proceeds of his work) or the tolerably good wage and free hand of a "club doctor."

I am, Sirs, yours obediently,

Aug. 2nd, 1892.

COMMON SENSE.

## MUSHROOM "POISONING."

To the Editors of THE LANCET.

SIRS,—Never does a mushroom season come round but one meets with cases of so-called poisoning. The best treatment seems to consist in the exhibition of copious draughts of warm water, which provoke easy vomiting; and, then, what does one see? Almost invariably that true mushrooms have been swallowed in chunks unbiten. These large flabby masses cannot be coaxed through the pylorus so must return through the œsophagus. And this is a case of "poisoning"! Let those of us who delight in the delicious ocellated fungus attend to the detail of well biting before swallowing and we run small risk of being poisoned by mushrooms.—I am, Sirs, your obedient servant,  
McKisham, Wilts, July 23rd, 1892.

S. GROSE.

## BOYS WITH FIREARMS.

It is sincerely to be hoped that the magistrates will deal seriously with boys in the possession of firearms. For that matter the possession of firearms by irresponsible adults of all kinds has long become a question of great importance, but in the case of boys the offence is without excuse.

*Mr. C. B. Statham* (Battersea-park).—The best way would be for our correspondent to apply to the Military Secretary, India Office, for the information. We have occasionally published samples of the questions put at the examination.

## MEDICAL ETHICS.

To the Editors of THE LANCET.

SIRS,—Hitherto the medical "gentlemen" practising their profession in the town in which I reside have always borne a high character for their gentlemanly conduct towards their professional brethren; but I am sorry to say it appears that we are now on the eve of losing our previous unblemished reputation, as the following will show. I have been for a long time medical officer to one of the largest railway clubs in — and have always tried to do my duty to its members when requiring my assistance. Of course, in club practice (as in private) it is not always possible to please every member, and sometimes it is not always policy for every member to consult their club doctor. But when that is the case, and when another practitioner is consulted, surely it is most unprofessional on his part to say, "If any of your members have a wish to change their doctor I will be glad to take his place." "Several members of your club appear anxious to have a change, as they are not satisfied with Dr. —," and so on. Conduct of that kind is reprehensible, and I hope you will mark your sense of its injustice in the usual manner.

I am, Sirs, yours truly,

Aug. 2nd, 1892.

M. D. &c.

ERRATUM.—In the letter which we published under the heading of "Cures" for Inebriety the word "vindicate" in the last line but five of Dr. Keeley's communication ought to be *indicate*.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Astley, Portobello; Dr. J. G. Adami, Cambridge; Mr. W. S. Andrew, Brixton Hill; Mr. Argo, Warrington; Mr. Anderson, London; Dr. G. Stewart Abram, Exeter; Mr. H. Andrews, Exeter; Mr. Armstrong, Walker-on-Tyne; Mr. Bonner, Suffolk; Mr. Behnke, London; Messrs. Bishop and Sons, London; Mr. Birchall, Liverpool; Messrs. A. P. Bush and Co., Boston; Dr. Brimacombe, Bristol; Mr. C. Beesley, Waltham Abbey; Dr. Bourke, London; Mr. Byrne, Wortham; Messrs. Burgoyne and Co., London; Mr. James Base, London; Dr. James Bays, South Hampstead; Mr. Alfred Browne, Osmotherly; Messrs. Challis and Co., Brighton; Mr. E. H. Collins, London; Mr. W. Watson Cheyne, London; Mr. Chibnall, London; Mr. Cotman, London; Mr. Thomas F. Chavasse, Birmingham; Mr. Bruce Clarke, London; Mr. Edward Cornish, Walthamstow; Mr. Carruthers, India; Mr. Cornish, Manchester; Mr. Davies, Birmingham; Mr. Eddington; Messrs. Eason and Sons, Dublin; Dr. Frank, Germany; Dr. Fitzpatrick, London; Professor Gafrdnor, Glasgow; Dr. S. Grose, Wilts; Mr. A. Gordon, Dublin; Mrs. Horn, Folkestone; Mr. Hutchinson, London; Dr. A. D. Hughes, Pembroke; Mr. Heywood, Manchester; Messrs. Hopkinson and Co., Nottingham; Messrs. Humphreys, London; Mr. Hunt, Manchester; Mr. F. G. Hallett, London; Mr. Jahucke, London; Dr. L. E. Keeley, London; Mr. Langley, Waterford; Dr. Lambert, British Columbia; Mr. W. Arbutnot Lane, London; Mr. Loveland, New York; Dr. Mackay, Devizes; Dr. W. V. McVey, Boston; Mr. Jabez Hogg, London; Mr. G. L. Morrigan, Weybridge; Messrs. Matthews Bros., London; Dr. B. G. Morison, London; Messrs. Mabbett and Edge, London; Mr. J. H. Morgan, London; Messrs. Medical Diary for the ensuing Week.

Monday, August 8.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.  
 Tuesday, August 9.  
 KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.

Wednesday, August 10.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Obstetrical Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 3 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, August 11.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.  
 Friday, August 12.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, August 13.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

SUBSCRIPTION.

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ..... £1 12 6 | Six Months ..... £0 10 3

TO THE CONTINENT, COLONIES, UNITED STATES, INDIA, CHINA, AND ALL PLACES

ABROAD ..... One Year 1 14 8

\* In consequence of the new postal arrangements, the Annual Subscription for India, China, and all foreign countries will now be reduced to £1 14s. 8d., instead of £1 16s. 10d. as formerly.

Post Office Orders and Cheques should be addressed to The Publisher, THE LANCET OFFICE, 423, Strand, London, and crossed "London and Westminster Bank, St. James's-square."

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance. Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

ABSTRACT OF A PAPER ON  
**EXCISION OF THE BREAST  
 FOR CANCER.**<sup>1</sup>

By **W. WATSON CHEYNE, M.B. ED., F.R.C.S. ENG.,**  
 PROFESSOR OF SURGERY AT KING'S COLLEGE; SURGEON TO  
 KING'S COLLEGE HOSPITAL, ETC.

[REFERENCE was in the first instance made by Mr. Cheyne to work done on this subject, especially from the pathological side, by various writers, notably by Dr. L. Heidenhain<sup>2</sup> in Germany and Mr. Harold Stiles<sup>3</sup> in Edinburgh, the methods advocated being based in the main on Mr. Stiles' work. A few remarks having been made on the question of the constitutional or local origin of cancer, Mr. Cheyne went on to discuss the exact nature and mode of spread of a cancer of the breast as follows:]

The view which I think is generally held is that the carcinoma begins as an overgrowth of epithelium in the acini or ducts of the breast, and that it spreads partly by epithelial projections from these acini or ducts pushing their way into the surrounding tissues and partly by fresh infection of neighbouring ducts or acini; and further, that the same overgrowth of gland epithelium which produced the original disease is liable to occur in other parts of the breast, giving rise to multiple breast tumours, and that it is to this fresh overgrowth that local recurrences are most commonly due where portions of breast tissue are left behind. The latter part of this view is, I believe, incorrect. No doubt the earliest commencement of a cancer must be in connexion with the gland epithelium, but I believe that once the disease has commenced the epithelial overgrowth soon pushes its way through the wall of the duct or acinus and passes then into the lymph channels and vessels surrounding it, and that having arrived there the subsequent growth of the tumour occurs entirely by multiplication of the original epithelial cells and their derivatives along these lymph channels. The cancerous tumour is, in fact, a growth in lymphatic canals, and the alveolar spaces are in the main dilated lymph vessels and spaces. Hence the cancer cells are in direct communication with the lymph stream from a very early period of the tumour formation, and are constantly liable to be carried away with the fluid lymph; and may either stick further on, giving rise to secondary nodules in the breast or surrounding fat and fascia, or may be carried to the nearest lymphatic glands, causing infection and tumour formation there. The neighbouring acini around a tumour do not form fresh growth; but, as can be frequently seen in microscopical specimens, they are simply pushed aside, undergo atrophy, and disappear. It can also be readily seen in recurrences in connexion with remnants of breast tissue left behind that although the glandular epithelium shows irritative changes, the cancerous growth has begun in the lymphatic vessels around; and Mr. Stiles has in a number of instances found plugs of cancer cells in lymphatic vessels in apparently healthy breast tissue far away from the primary tumour. Hence the main point to be considered in connexion with the spread of a cancerous growth in an organ is the disposition of the lymphatic vessels in that organ and the paths along which the lymph leaves it.

According to M. Sappey, the mamma is supplied with extremely numerous lymphatics. They commence in connexion with the acini in the form of a plexus around them; they then collect on the surface of the lobule, completely enveloping it in a close plexus, and the plexuses of neighbouring lobules communicate. From the lobules they run along the ducts, still in a plexiform arrangement around them, and so they pass from all parts of the breast towards the nipple. Under the areola the vessels, now of considerable size, form a plexus, called by M. Sappey the sub-areolar plexus, which is also joined by the vessels from the skin of the areola and its neighbourhood. From this sub-areolar plexus the lymph is carried towards the axillary lymphatic glands by larger

vessels, of which he describes four, two from the centre and one from the upper and lower part of this sub-areolar plexus respectively. According to M. Sappey, the whole of the mammary lymph follows the above-mentioned course, but subsequent observers have stated that there is also a plentiful return from the under surface of the gland through the pectoral fascia, and this corresponds with the pathological facts, which leave no doubt on that matter. It follows, however, from Sappey's investigations that at whatever part of the breast a cancerous tumour is formed, though some of the infective material will be carried directly in the pectoral fascia and fat to the axilla, part may also pass through the gland itself towards the nipple. Even where the tumour is at the extreme axillary end of the breast—under which circumstances some surgeons advise removal of the tumour alone, although there may be direct flow towards the axilla—there is also a flow backwards through the mamma towards the nipple and infective material may thus very readily be left behind if the tumour alone is removed. Hence, I believe, that in the case of the breast it is absolutely necessary to remove the whole organ wherever the tumour be situated, because it is quite impossible to say what parts are free from the disease and what are not, and I see no reason for running any risk of recurrence by leaving portions of the breast behind. It is, however, easier to speak of complete removal of the breast than to do it, for it turns out that the breast is a much more diffuse and extensive organ than has been supposed. This has been demonstrated by Mr. Stiles by a very simple method, which I must refer to as it is one of great practical value in determining during the course of an operation not only whether the whole breast but also whether the whole disease has been removed. Mr. Stiles found that when a cut surface on which masses of cells—e.g., epithelial masses—were present was first washed free from blood, then immersed for five minutes in a 5 per cent. solution of nitric acid and then washed under the tap for five minutes, the epithelium was readily differentiated from the other tissues by the naked eye, presenting the appearance of dull white spots or masses, while the fat became yellow and the fibrous tissues welled up and became semi-transparent. By treating the breast in this way after removal it is easy to determine whether lobules of the breast or nodules of cancer have been cut through. In practice, as soon as the breast is removed, it is handed over to an assistant, who puts it through the above process while the operator is going on with the dissection of the axilla. By the time the axilla has been thoroughly cleared out the breast is ready for inspection and can be carefully examined before closing the wound, and if any portion of breast tissue or of disease is detected the remaining part is at once sought for and freely removed. I have always used this plan since Mr. Stiles told me of it; and in one very advanced case I found by means of it that I had cut through a nodule of disease in the fat at the outer border of the axilla, which I would certainly have overlooked otherwise, and on searching I found the rest of the nodule and removed it. Mr. Stiles' nitric acid method is also applicable to tumours elsewhere; and in one case, where I was removing an epithelioma on the inner side of the cheek, and involving the lower jaw, I detected by means of it a narrow strand of disease running backwards beneath the ramus of the jaw, which I had not observed on dissecting away the growth. I consider this method a very valuable addition to our operative means, the only objection to it being, I think, the length of time that it takes. In the case of the breast it is necessary to cut off the breast from the axillary fat before clearing out the contents of the axilla in order to have it tested, whereas I find that I can get the axillary fat and glands away much more readily by leaving the breast attached, the weight of the mamma hanging over the side pulling down the axillary contents more easily than can be done by the hand. This is, however, a minor objection, and Mr. Stiles may perhaps be able to meet it.

To return now to the extent of the breast, it is found to reach laterally in all directions, especially upwards and towards the axilla, much further than has been supposed, and it is impossible to remove it completely by the small elliptical incision figured in the older text-books. In order to take away the breast completely it is necessary that the incisions should extend well beyond it at each end and that a large amount of skin, I believe an amount coextensive at any rate with the bulging portion of the breast, should be removed. For another reason it is necessary that large portions of skin should be included between the in-

<sup>1</sup> Read at the Nottingham Medico-Chirurgical Society on April 20th, 1892.

<sup>3</sup> Edinburgh Medical Journal, June and July, 1892.

cisions—viz., in order to ensure the removal of the sub-areolar lymphatic plexus and the vessels proceeding from it towards the axilla, and also to take away as far as possible the bands of fibrous tissue which pass from the breast to the skin, the suspensory ligaments of the mamma, which have been found very frequently to contain breast tissue as well as lymphatic vessels coming from the breast, and which are therefore a source of risk. Further, the skin over the tumour wherever situated should be widely removed, even although it is not actually involved in the disease, and that for the same reason—viz., that the bands of fascia running from the neighbourhood of the tumour to the skin are very likely indeed to be infected with the disease. Where the skin has itself become involved in the disease—to however small an extent—it must be very freely removed; I should say, some three or four inches clear on each side of the nodule, for the lymphatic plexuses in the skin are very numerous, especially at the deeper part, where the vessels are largest. Hence, as regards the skin incisions, no absolute rule can be laid down; they must be planned so as to ensure complete removal of the breast and to get wide of the disease, and must usually be irregular in shape. As I said before, they should include practically all the prominent part of the breast and when the growth is above or below the centre of the breast further incisions must be made at right angles, so as to include it. As a rule, even where the removal of the skin has been very extensive, I have generally succeeded in bringing the edges together and thus getting union by first intention by undermining the skin widely and by using button stitches and relaxation sutures of silver wire. Where, however, the skin cannot be brought together at all, or where the patient is very spare and the traction is likely to lead to sloughing, the wound can be readily closed by Professor Thiersch's method of skin-grafting, as described by me in THE LANCET last summer, the grafts being either applied at the time or, if the patient is at all collapsed, after an interval of about ten days.

Although Mr. Sappcy was of opinion that the whole of the mammary lymphatics ran forwards and joined the sub-areolar plexus, it seems clear from the researches of Mr. Langhans, Dr. Heidenhain, Mr. Stiles and others, and also from clinical experience, that many lymphatics must leave the breast on the under surface and run in the pectoral fascia, generally along with bloodvessels, towards the axillary glands; some, however, I believe, also go towards the anterior ends of the intercostal spaces, where they pass into the thorax and join the anterior mediastinal glands, communicating also, I think, with lymphatics about the sternum. Hence it is essential to remove the pectoral fascia thoroughly coextensive with the mamma and right on to the sternum. Besides the presence of lymphatics Dr. Heidenhain and Mr. Stiles have found that many lobules of the breast are intimately connected with the pectoral fascia, and would certainly be left behind if the breast is simply torn off as is sometimes done. Indeed, so intimately is the pectoral fascia connected on the one hand with the breast and on the other with the pectoral muscle, that Dr. Heidenhain states that it is necessary in all cases not merely to try to dissect the fascia off from the muscle, but also to remove a thin layer of the surface of the pectoral muscle. This is certainly necessary under the tumour and under the central mass of the breast; I doubt if it is so necessary under the peripheral parts of the breast. Dr. Heidenhain found that where the skin was freely removed the recurrences practically always took place in connexion with the pectoral fascia.

If the tumour has become adherent to the pectoral muscle the free removal of the affected part is of course indicated, but we must bear in mind that the majority of the lymphatics in muscle run parallel with the muscular fibres, and hence the mere cutting a circular piece out of the muscle will not suffice; the whole strip of affected muscle must be removed. Dr. Heidenhain points out that the muscular contractions tend to force on any infective material along the lymphatics, and he holds that once a muscle is attacked, even at one place only, the whole muscle should be looked on as diseased, and should therefore be removed. I doubt, however, whether with a small involvement of the pectoralis major it is necessary to remove the whole muscle. I should in such a case only remove a quantity of muscular tissue on each side, being careful, however, to take the whole length of the fibres as far as possible. The spread of cancer in muscle is a matter of great importance in cases of the malady affecting muscles elsewhere, especially in the case of the tongue, where, as we know, recurrence is extremely apt to occur, mainly, I

think, because the whole of the muscles affected is not removed.

In the axillary space the main lymphatics run in the fat towards the glands, but some also, I think, run in the fascia over the serratus magnus, and some upwards between the pectoralis major and minor to enter the axillary space above the latter muscle. It is well, I believe, always to remove the fascia over the serratus as far back as the latissimus dorsi, where I have more than once found nodules of cancer, and also to remove the layer of fat and fascia which one finds between the pectoralis major and minor towards the outer part, where also I have found disease. Lastly, it is imperative in all cases to remove all fat and glands from the axilla whether there is any noticeable disease or not, for the glands are usually very early affected, and the mere absence of hardness does not necessarily imply absence of disease. Further, it is not sufficient simply to pull out the glands which are felt to be enlarged, the fat and glands must be removed completely by careful dissection, and that for three reasons. In the first place, as I have mentioned, in the early stage the infected glands are not noticeable, and the removal only of enlarged glands does not necessarily mean removal of all the disease; in the second place, if only the glands are taken away, the lymphatic vessels are left in the fat and these are often found plugged with cancer cells some distance from the glands; and thirdly, it is advisable to remove all the fat, because Mr. Stiles has shown that fresh formation of lymphatic tissue frequently occurs around certain fat lobules under the irritation from the breast disease, and these new lymphatic glands may subsequently become the seat of disease. These fat lobules arc, according to Mr. Stiles, lymphatic glands which have undergone fatty involution and again become lymphoid in consequence of changes in the mamma set up by the presence of the tumour.

To sum up: in all cases there should be free removal of the skin, especially over the tumour, very free indeed if the skin is actually the seat of disease; complete removal of the breast, bearing in mind its great extent; removal of the pectoral fascia coextensive with the breast and right on to the sternum, along with a thin layer of the muscle behind the tumour and the main part of the breast; removal of the fascia over the serratus magnus in the axillary region and of all glands and fat from the axilla, not by pulling out the glands, but by clean dissection; further, if the tumour is adherent to the pectoral muscle, removal of large strips of that muscle. This may seem a very extensive operation where the tumour is small, but the object of the operation is not to remove the tumour but to rid the patient of her disease, and that can only be done by removing, as far as possible, all the probable seats of recurrence. The operation is fortunately one in which, if performed aseptically, the question of mortality does not come into play, and the results of this very free removal seem to me to promise well. Although I have been brought up to deal more freely with these cases than used to be the fashion, my impression is that there has been an improvement as regards recurrences since I began to act closely in accordance with these recent pathological researches. During the last two years I have operated in this free manner in over twenty cases, and, so far as I am aware—and I know about the majority of the cases—recurrence has only as yet taken place in three instances, in one case being intra-thoracic, and in another—the second of the cases of skin grafting which I published in THE LANCET of last year—in the form of a small nodule in the skin over the angle of the scapula, three inches and a quarter away from the edge of my former incision in the skin—a striking instance of the necessity of free removal of the skin once it has become involved in the disease.

**THE PROPOSED ISOLATION HOSPITAL AT EPSOM.**—Mr. Jacob, the medical officer of health, has reported on the respective merits of the two proposed sites for the isolation hospital intended to be erected at Epsom. Of these, that in the Dorking-road is, in Mr. Jacob's opinion, inferior to that in Kingston-lane, and this view was adopted by the local board.

**SEWERAGE OF ST. ANNE'S-ON-THE-SEA.**—The Local Board has adopted plans for an extensive new sewerage scheme, which includes all that part of the town not built upon and likely to be utilised for building purposes for some years to come. The central authority has sanctioned the borrowing of £9783 for carrying out the scheme.

# Post-graduate Lecture ON ABORTION.

Delivered at Charing-cross Hospital,

By WILLIAM DUNCAN, M.D.,  
OBSTETRIC PHYSICIAN TO THE MIDDLESEX HOSPITAL.

GENTLEMEN,—As the subject I have chosen for this lecture is one of such great importance, both to the community at large as well as to us medical practitioners, I feel it is unnecessary for me to apologise for bringing it before your notice to-day. Unfortunately, however, the time at my disposal will not permit me to treat of it exhaustively, but I shall endeavour to discuss it in a practical manner. Abortion may be defined as the separation and expulsion of the contents of the gravid uterus at any time before the seventh month (i.e., before the viability of the fœtus). It is said to occur more often in young girls; also in women approaching the climacteric. Multiparous women are more liable to abort than primiparae, and women who have once aborted are prone to a recurrence at the same period in subsequent pregnancies. This is accounted for either by (a) the recurrent death of the fœtus or by (b) the persistence of the cause which produced the first (as flexions, uterine tumours, or endometritis). In some cases no local cause can be found, and then it is thought that some undefined constitutional irritability exists, which only permits the uterus to reach a certain degree of development. Abortion is said to occur most frequently between the ninth and sixteenth weeks; doubtless, however, many unrecognised early abortions take place when a woman misses a period, and then has an excessive one, accompanied by clots, she probably has been pregnant without knowing it.

The causes may conveniently be arranged under the headings "pathological" and "accidental," as follows:—

Abortion	Pathological	Reflex	Lactation, gastric irritation, neuralgia, toothache, rectal irritation, operations.
		Systemic	Scarlet fever, typhus fever, typhoid fever, relapsing fever, small-pox, cholera, syphilis, chorea, noxious gases inhaled, plumbism, pertussis.
	Local	Uterine flexions, fibroids, polypi, endometritis and cervicitis, lacerations of cervix, pelvic adhesions, diseases of the ovum or its membranes.	
	Accidental	Physical	Blows, falls, excessive coitus &c.
Psychical		Fright, anxiety, fear, anger &c.	

Most of the causes under the first head act by inducing the death of the fœtus. The reflex causes act by irritation of the excito-motor nerves. Lactation is a common cause, as about 17 per cent. of the women who suckle whilst pregnant abort. According to Tyler Smith, this is due to the double excentric irritation of the diastaltic function proceeding from the uterus and the breast; doubtless the woman's anæmic condition is also a factor. Gastric irritation giving rise to obstinate vomiting may end in abortion, so also may severe neuralgia. Strong purgatives causing rectal irritation have been known to produce expulsion of the uterine contents. The same result may follow operations performed during pregnancy, especially if done on the genito-urinary organs, and at a time corresponding to what would have been a menstrual period. The result is due to shock, and not to pyrexia following the operation. On the other hand, it must be remembered that many operations (even single and double ovariectomy) have been performed on the gravid woman without interfering with gestation; but care should be taken to choose a time between the menstrual epochs. I have operated on an extensive perineal rupture when the patient was two months pregnant; she did not abort, neither did the new perineum give way during the subsequent parturition.

Many systemic diseases (as seen from the table) are liable to produce abortion, but the most potent of all is syphilis, especially if both father and mother be syphilitic. The effects of syphilis are so far reaching and long continued that if the general public had any idea of them it can hardly be

doubted but that they would demand that the Contagious Diseases Act (which was repealed owing to the agitation of some sentimentalists and would-be upholders of the "liberty of the subject") should be again put in force. The effects of lead on the gravid state are interesting, for the pregnant woman is liable to abortion not only when she suffers from plumbism, but also, when being herself free from the taint, her husband is a lead worker. Any local disease which interferes with the proper development of the uterus or its lining membrane may cause abortion—retroflexion more often than pathological antelexion, as in the latter condition the woman is frequently sterile; if, however, she does conceive, abortion is likely to follow. A series of early abortions is due to either retroflexion or syphilis. Endometritis and endocervicitis are, according to Whitehead, common causes of abortion. Out of 378 abortions he traced 275 (nearly 73 per cent.) to disease of the lower part of the uterus; hence the importance of treating well-marked endocervicitis during pregnancy. Extensive laceration of the cervix in a former labour is given as a cause, and there is no doubt that pelvic adhesions (the result of a peritonitis) which bind down the uterus in the pelvic cavity may prevent its growth and evolution.

With regard to the accidental causes, there is no doubt that a great mental shock may bring on an abortion, not only by inducing uterine contraction, but also by causing the sudden death of the fœtus. In bygone times, under the influence of terror and pain, martyred women are said to have aborted at the stake, and condemned women have been known to abort prior to execution; indeed, in some women the dread of a miscarriage may bring it about (Priestley). Up to the end of the third month the ovum comes away in its membranes, but after that time in the usual way with pains, escape of the liquor amnii, then expulsion of the fœtus followed by the placenta. The symptoms are essentially two—hæmorrhage and pain. In the first two months the hæmorrhage is like a profuse menstruation; the pains are due partly to uterine contraction and partly to the expulsion of clots through an imperfectly expanded cervix. These symptoms may last three or four days, and, as the ovum either passes in pieces or is surrounded by clots, these early abortions are often looked upon as merely retarded and profuse periods. After the second month other symptoms are met with, as bearing-down pains in the pelvis, a watery discharge takes place, and then the hæmorrhage and pain set in. The hæmorrhage may be slight and soon stop, or it may gradually increase in amount. In some cases it stops for a short time and then recurs; the uterine contractions become more and more severe until the ovum is expelled. Sometimes the pain precedes the hæmorrhage. In other cases there may be no pain; and these are more hopeful with regard to checking the threatened abortion. When the abortion occurs in the early months and the fœtus has died some time previously, there is often no trace whatever of it to be found. When the extravasation is considerable it sometimes breaks through the decidua vera and gets between it and the decidua reflexa, or it may take place outside the reflexa, dissecting it up. The pressure upon the ovum causes rupture of the sac and escape of the amniotic fluid; then, if the uterine contents be not expelled, the fœtus and membranes surrounded by coagulated layers of blood form what is called a "mole"; when the coagula are fresh it is called a "blood mole"; but when they have undergone more or less organisation it is called a "fleshy mole." These moles are seldom bigger than the fist and are usually expelled between the third and fifth months.

If in any case there be abnormal adhesions between the decidua and uterine wall, when abortion occurs the ovum escapes and then it frequently happens that retraction of the uterus on its contents takes place, the cervix closes and the patient has an incomplete abortion. In a case of this kind the following terminations may result: (a) The hæmorrhage continues and the retained products of conception are gradually thrown off by being loosened from the uterine wall owing to retrograde changes taking place in them; or (b) the hæmorrhage may cease altogether for days or weeks, and then sudden uterine contractions with profuse hæmorrhage take place and the uterus is emptied. (c) Putrid decomposition of the retained products sets in, especially when they are completely separated from the uterine wall. This decomposition is brought about either by the entrance of air by the introduction of the finger, or when part of the ovum hangs through the os uteri, the decomposition extending upwards from the vagina. Septicæmia does not often occur,

as the decomposition usually takes place late when there are granulations on the uterine surface and the sinuses are closed. In these cases high and irregular temperature with perhaps attacks of flooding set in, and these continue until the uterus is emptied either naturally or artificially; sometimes pelvic peritonitis and cellulitis occur. Numerous examples of this result of incomplete abortion have come under my care at various times. (2) Lastly, there may be formed a so-called "placental polypus." In these cases a bit of placenta or decidua remains firmly attached to the uterine wall and has some fibrin deposited upon it from the extravasated blood, or the fibrin may be deposited on the rough placental site, and thus form a polypus. These polypi give rise to sudden floodings, or they may decompose and set up septic absorption. After an abortion the uterus undergoes involution as after labour at term; and as women take little care of themselves after an abortion, as a rule, this accident often results in chronic uterine disease.

The diagnosis of abortion is made from the hæmorrhage, pain and dilatation of the cervix; perhaps part of the ovum may be felt; this might be mistaken for a soft polypus, but in the latter there is no history of pregnancy. All clots passed should be carefully broken up in water, because the embryo may be inside one, and thus be easily missed without a thorough examination. If there be no clots to examine and we find the hæmorrhage and pain have ceased, then we cannot be certain whether the uterus is empty or the threatened abortion has been staved off; but if later on hæmorrhage recurs and the uterus has not gone down in size, or an offensive discharge sets in, then we know an incomplete abortion has taken place.

The prognosis of abortion (when not criminal) is very good if it be properly managed. Death, however, may result from hæmorrhage, septicæmia or peritonitis. Two hundred and thirty-four cases were treated at the Rotunda Hospital with only one death, which was due to heart disease. After criminal abortion death is common; thus of 116 such cases collected by Tardieu 60 women died.

The treatment of abortion may be considered under the following heads:—(1) The Prophylactic Treatment; (2) the Treatment of Threatened Abortion; (3) the Treatment of Inevitable Abortion; and (4) the Treatment of Incomplete or Neglected Abortion. The prophylactic treatment is most important. Whenever a patient gives a history of having had one or more previous abortions a thorough investigation of both her and her husband must be undertaken, and if any constitutional disease be found it must be carefully treated. Syphilis is the most frequent and important disease, and whenever it is suspected both husband and wife should undergo a thorough course of antisiphilitic treatment before the risk of pregnancy is again incurred. The results are often most gratifying. A patient contracted syphilis from her husband and had four miscarriages within the first two years of her married life. She had marked endometritis, which I treated by the local application of the acid nitrate of mercury. At the same time she and her husband underwent a six months' course of treatment, with the result that she now has two healthy children. Diday maintains that it is not sufficient to give mercurials before pregnancy takes place, but that they should also be administered during each successive pregnancy, even though the woman shows no signs of syphilis. Personally I believe in combining iodide of potassium with perchloride of mercury in these cases, and even if there be no syphilis the above combination exerts a beneficial action on the uterine mucous membrane.

If a patient be gouty or rheumatic, treatment appropriate for these conditions must be ordered. Anæmia requires iron in some form or other. A course of water and baths at Schwalbach or Kissingen often proves most beneficial. Any local malcondition should be remedied. If there be uterine displacement it must be set right and a suitable pessary introduced. This should be removed after the fourth month, when the uterus has risen out of the pelvic cavity. Marked endocervicitis with erosion of the os uteri should be treated by the careful application of carbolic acid or nitrate of silver. In some diseases of the placenta causing intra-uterine death of the fœtus, the late Sir James Y. Simpson thought that the administration of twenty grains of chlorate of potash three times a day during pregnancy averted abortion by increasing the oxygen in the mother's blood. In women who abort at the same period in several successive pregnancies, and in whom no disease of

ovum or uterus can be discovered, absolute rest in bed at the approaching period of danger must be enforced, whilst nerve sedatives such as bromide of potassium and tincture of sumbul should be administered. When abortion is threatened a vaginal examination must always be made in order to find out the state of the uterus. If any portion of the membranes has been passed it is hopeless to attempt to check the abortion, so also if any portion project through the os uteri or be in the vagina. If we can touch the ovum with the finger in the cervical canal, the case is desperate but not hopeless; if the os uteri be closed, the hæmorrhage slight and the pains mild or disappearing, the case is very hopeful. The patient must be kept absolutely at rest in bed in the horizontal position; no pillow under the head but one under the pelvis helps to drive the blood away from the pelvis. The room is to be kept cool; the patient should be given liquid food, to be taken cold; no stimulants must be given; and the bowels are to be regulated by a gentle laxative, such as cascara sagrada or a drachm of glycerine injected into the rectum. The practice of applying cold to the lower abdomen and the vulva is not a good one, as it is likely to bring about what we wish to avoid—viz., uterine contraction. With regard to drugs, my rule is that if both hæmorrhage and pain be present I give a mixture to be taken every three hours, each dose consisting of liquor morphia hydrochloratis, 20 min.; compound tincture of chloroform, 20 min.; acid infusion of roses to 1 oz. If, however, there be no pain whatever, but simply the hæmorrhage, I find the liquid extract of ergot given in ten-drop doses every two or three hours to be of the greatest use in causing gentle tonic contraction of the uterus and controlling the hæmorrhage. The American physicians largely use and believe in the efficacy of one-drachm or two-drachm doses of the liquid extract of viburnum prunifolium (or black haws) given every few hours. If the treatment adopted stops the threatened abortion the patient should be kept in bed for a week after all symptoms have disappeared. If, however, the hæmorrhage becomes more copious with clots, and accompanied by pains increasing in severity, together with a dilated cervix and the escape of the liquor amnii, or if the ovum or pieces of the decidua be found in the vagina or in the clots passed, then it is almost certain we cannot prevent abortion taking place. It is, nevertheless, remarkable how in some cases the gestation may go on when one would imagine it could hardly possibly do so.

At the present moment a patient is daily expecting her first confinement; when she was between two and three months pregnant she had severe hæmorrhage, with pains. On examination the os uteri was dilated to the size of a shilling and the ovum was readily felt by the finger inserted through the os uteri. As rest and sedatives for two days caused no change I concluded nothing could stave off abortion, so I gave drachm doses of ergot every three hours, expecting this to be followed by the expulsion of the uterine contents, instead of which the hæmorrhage ceased, the os uteri closed and the patient has gone on to full term. Last year I saw a lady in consultation with my friend, Mr. Walker of Willesden. When between three and four months pregnant she was seized with hæmorrhage and pain, and had a profuse watery loss, so that it was thought the liquor amnii had escaped and that of course the abortion was inevitable. As, however, there was no dilatation of the os uteri, we decided to keep the patient absolutely quiet and to give sedatives. This treatment was carried out for some weeks, and the patient ultimately was delivered by Mr. Walker of a fine, healthy child by means of forceps. Scanzoni mentions the case of a woman who, when three months pregnant, had profuse hæmorrhage with clots; as all hope of staving off the abortion was abandoned, large doses of ergot were administered; the vagina was plugged for thirty-six hours, the sound was passed and the uterine contents stirred up. Lastly, at the end of three weeks' flooding a solution of perchloride of iron was injected into the uterus; but notwithstanding all this the woman quickened two months later.

The treatment of inevitable abortion depends on how far the gestation has advanced. In the first two months it is rarely necessary to do more than keep the patient at rest and give one-drachm doses of ergot three or four times a day. If, however, the hæmorrhage continues, showing there is incomplete detachment of the decidua, it is essential to dilate the cervix (in the manner to be presently mentioned) until the forefinger can be introduced into the uterine cavity and the uterine contents removed. During this manœuvre the uterus must be held steady by

the other hand placed over the abdominal wall. In cases where the decidua are very adherent it is necessary to curette the uterus carefully and completely with every antiseptic precaution. After the second month the ovum is either thrown off entire or the sac ruptures and the ovum escapes; the treatment in either case is to empty the uterus. If the cervix be dilated one or two fingers (thoroughly cleaned and dipped in a perchloride solution) are passed through the os. In order to do this it may be necessary to introduce the whole hand into the vagina, but this is a painful procedure and, as a rule, requires anæsthesia. Having got one or two fingers into the uterine cavity, they are gently insinuated along one side up to the fundus and then down the other, so as to completely surround the ovum and effect its expulsion, all the while keeping up steady pressure on the uterus externally. If the cervix be undilated (and this is one of the difficulties) it must be dilated. A very good plan is to tampon the vagina; by this means the hæmorrhage is checked, and in seven cases out of ten, on removing the tampon in about twelve hours, the os uteri will be found dilated and the ovum projecting. Plugging the vagina, to be of any use, must be done properly; on an emergency a soft towel, handkerchiefs, or strips of linen will do, but sponges are bad. The best method is as follows: Tie about a dozen pieces of cotton wool (each the size of a Tangerine orange) on a piece of string, each plug being about six inches from its neighbour; put them in a 1 in 3000 perchloride or 1 in 50 carbolic solution. Next irrigate the vagina with some of the solution, and with the patient in the left semiprone position pass a Sims' speculum. Take the plugs out of the antiseptic solution, squeeze them dry and then pack the vagina, first of all packing carefully all round the cervix in the cul-de-sac and then the vagina below the level of the cervix, using more plugs if necessary. The tampon is removed after twelve hours, and if then the cervix be undilated some recommend re-tamponing once or twice more, but to this there is the grave objection that the plugs may become offensive and the patient runs the risk of septic poisoning. The tampon is exceedingly useful if the patient is collapsed from excessive hæmorrhage, as it gives her time to rally, and stimulants as well as nourishment can be administered; but if there be no collapse, or if after using the tampon once the cervix be still undilated, I am confident that no plan of treatment can compare with rapid dilation by means of Hegar's dilators. This is done as follows: the dilators, speculum and vulsellum forceps are placed in a perchloride solution; the patient is then placed either in the semiprone or lithotomy position, and it is not absolutely necessary, unless she be very nervous, to give an anæsthetic; next Sims' speculum is passed and given to a nurse or assistant to hold, the anterior lip of the cervix is seized with a pair of vulsellum forceps, and a douche given; then one dilator after another is passed with perhaps a minute's interval between each, until the cervical canal will readily admit the finger; then the uterine contents are carefully removed either with the finger or a curette, the cavity is well douched with the perchloride solution by means of a double catheter, and a pencil consisting of twenty grains of iodoform is passed up the cervical canal, the vulsellum removed from the cervix, and a couple of cotton-wool plugs soaked in glycerine pushed up the vagina; the speculum is removed and the patient put back to bed. As a rule she suffers practically no subsequent pain, and it is rarely necessary to give a one-third of a grain of morphia suppository; the plugs are allowed to remain in about twelve hours, then removed and an iodine douche given night and morning for about a week after. Having carried out this routine treatment in dilating the uterus and removing its contents in (I may say) hundreds of cases, I feel justified in asserting that it is practically devoid of risk. The use of tents is, if possible, to be avoided as they may set up septic trouble and they have been known to cause death from tetanus as well as from septicæmia. If ever employed, the tents should have been previously soaked in an ethereal solution of perchloride of mercury. The use of the ovum forceps is, I think, dangerous, but careful and gentle curetting is, in my experience, quite safe.

In the treatment of incomplete abortion, when the uterus has been completely emptied all hæmorrhage ceases, but if after the patient begins to get about she suffers from recurrent losses of blood, and especially if the discharge be at all offensive, it is pretty certain that some foetal product remains behind. Sometimes the remains may be removed by disintegration or suppuration, but the patient runs great risks

of septic absorption with pelvic inflammation and a fatal result may ensue; but even in cases where there is nothing but repeated losses the patient's general health and strength becomes seriously impaired, so that in all cases of hæmorrhages continuing after an abortion has taken place, and where a week's trial of ergot in one-drachm doses every three hours with perfect rest does not effect a cure, the proper treatment is to dilate the cervix in the manner already described and to remove the retained products either with the finger or curette. It is remarkable how an extremely small bit of placenta left adhering to the uterine wall will give rise to profuse hæmorrhage. I have treated several cases where the piece was not larger than the little finger nail. An excellent example of the kind I saw a few weeks back in consultation with my friend Dr. Waterhouse of West Hampstead. A patient of his in her second pregnancy aborted about the third month (during his absence from town); the ovum and membranes were not found, and notwithstanding rest and ergot the hæmorrhage persisted on and off for some weeks. When Dr. Waterhouse first examined the patient he found the os uteri closed and the uterus only slightly larger than normal. On my examining her I found the condition exactly as above, but looking at the fact that the hæmorrhage recurred sharply I thought most likely something remained behind and I recommended dilatation and curetting. This I did with Dr. Waterhouse's help, and we removed a distinct but small bit of placenta about half the size of a hazel nut. All hæmorrhage ceased from that day and the patient was well in a week. It is well to remember that in the fourth month of gestation two fingers can be introduced, at the sixth month half the hand, and after the seventh month the whole hand, into the uterine cavity.

### DANUBIAN (?) FEVER.

By T. OLIVER, M.D. GLAS., F.R.C.P. LOND.,  
PHYSICIAN TO THE ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

THE interesting paper which appeared in THE LANCET of June 18th upon "Fever prevalent on the Shores of the Mediterranean and Red Seas" has suggested to me the advisability of bringing under the notice of the profession a type of fever which sailors and others who have recently visited the Danube have exhibited either when there, during the voyage homewards, or after reaching this country. The important point which Dr. Hutchinson Milnes in the paper just alluded to wishes his readers to remember is that the same kinds of fever occur in all parts of the basins of these two seas—in other words, "a case of fever at Sawakin or Massowah will not present features essentially different from those of a case treated at Malta or Naples. These fevers, excluding the exanthemata, typhus fever and influenza, comprise typhoid and malarial fevers as well as a febrile disease which is called by some local name in every district of the area under consideration, and is regarded by the inhabitants as peculiar to each locality, but which," Dr. Milnes feels convinced, "is actually the same throughout the whole region. This is the Malta fever of Malta, the Rock fever of Gibraltar, the Cretan fever of Crete and the local fever of the Red Sea ports, including Massowah. It has been thought by many to be malarial, by some to be closely allied to typhoid fever, or, indeed, to be typhoid fever in a masked form, and by others to be a compound of typhoid fever and malaria which they have called typho-malaria." Dr. Milnes' long service as a naval surgeon in the Mediterranean and Red Sea has given him an experience of this particular kind of fever which is neither typhoid nor malarial, and allows him to speak with authority upon a subject to which he has given considerable attention.

Within the last few months six or seven cases of fever contracted upon the Danube have come under my observation, which for brevity's sake when demonstrating them to my clinical class I have spoken of as Danubian fever. The first case I saw was in South Shields in consultation with Dr. James Drummond of that town, and was that of a young gentleman aged twenty-five, who had undertaken a voyage up the Mediterranean, the vessel ultimately making its way to the Danube, where it remained a few weeks. Here the patient was seized with an illness which was regarded as "fever and ague," and on reaching Malta he was transferred to the

hospital, where he lay for a few weeks, there being at this time vomiting and diarrhoea. Frequently the stools contained small quantities of blood. He recovered sufficiently to sail to South Shields, where he was seen by Dr. Drummond. At our consultation two days afterwards we found him bathed in perspiration. There had been rigors. The temperature was 104° and 105° in the evening. There were œdema, hæmaturia and an enlarged spleen, the other organs being apparently healthy. The case was not one of acute nephritis. There was something about it which made us both regard it as a type of malarial fever. We gave him large doses of quinine every three hours, and in a few days afterwards liquor arsenicalis. Within ten days blood and albumen had entirely disappeared from the urine, the temperature had fallen to the normal, œdema had disappeared, and the patient was quite well. Since then Dr. Drummond has had a similar case from the same river with more pronounced ague-like symptoms, accompanied by hæmaturia, in whom, although badly borne at first, the symptoms rapidly subsided upon the administration of small but increasing doses of quinine.

My second case is that of G. L.—, aged twenty-seven, a seaman, who was admitted into the Newcastle-on-Tyne Infirmary complaining of pain in the abdomen with giddiness and sickness of five weeks' duration. His father died of heart disease, his mother from an illness the name and cause of which are unknown, whilst a brother died at the age of twenty-six of phthisis and a sister of the same disease at the age of twenty-four. Eight weeks before admission the patient was on the Danube at Ibraila. The drinking water was very impure; it had a peculiar taste. The ship had run short of water, so the tanks were filled from the Danube. Twelve days after drinking this water the patient was seized with a colicky pain in the abdomen; a few hours afterwards he became delirious, and remained thus for two days. This attack lasted eight days, vomiting as a symptom being absent from first to last. Two weeks after his recovery he landed in England. Within the next few days he had a return of the fever and suffered much from pain in the front and back of the head. He was extremely prostrated by it. Vomiting now occurred, and during it he brought up a small quantity of blood. There was diarrhoea, accompanied by the presence of blood now and again in the stools. He recovered fairly well from this, but felt extremely weak. He could not walk without feeling as if he were going to fall, owing to vertigo. It was in this condition that he was admitted into the infirmary. There was considerable sallowness of the skin, but this, he said, was natural to him. The tongue was furred, the appetite good, the bowels irregular, sometimes as many as three stools daily and then perhaps no stool for a day or two. The highest temperature was 100°; the pulse ranged from 60 to 72. The heart and lungs were healthy. The area of hepatic dulness was normal, whilst that of the spleen was much increased. The urine was acid, but did not contain albumen.

The only other case that I shall mention is that of O. I.—, a Swede aged thirty-two, admitted into the infirmary a few days after the last patient, complaining of pain in the abdomen, of weakness and loss of flesh. On board the ship he had partaken freely of vegetable food and lime juice. Seven weeks before admission he had "fever" whilst at Ibraila on the Danube. There were diarrhoea and vomiting. He sailed to Gibraltar, where he was admitted into the hospital, and after a short residence there he came to the Tyne. When I saw him his tongue was very furred, he was sallow and anæmic; the bowels were regular, his gums were spongy, but had not bled; the liver dulness was enlarged and the area of splenic dulness was very much increased. On microscopical examination the blood did not exhibit any peculiarity except that the red cells did not form rouleaux. The urine contained albumen. In a few days after the administration of quinine the albumen disappeared from the urine and the patient was soon well.

The patients whose histories I have briefly recorded were seen by me some time after the original attack had been passed through, so that it is impossible to be perfectly accurate in regard to the exact nature of the illness at its commencement; but when observed later on it was clear that whilst they presented symptoms suggestive of malarial poisoning, the disease was neither pure malaria nor was it typhoid fever. In one of the cases, if not in all, the drinking water was apparently the cause of the illness; but the interesting point is that all the patients had been for some time, longer or shorter, on the Danube, and when they came under observation

they presented some of the symptoms of malaria, accompanied in almost every instance either by hæmaturia or albuminuria and presenting enlargement of the spleen. The tongue, too, as in Dr. Milnes' cases, was very furred. Whether they are to be regarded as cases of local fever to which the term "Danubian" may be applied, just as we speak of Malta, Gibraltar, or Cretan fever, will depend upon the experience of the profession and their record of a sufficiently large number of cases drawn from the same area and presenting symptoms similar to my own. The largest number of cases came under my notice in October of last year. That they were due to the entrance into the system of some poison there can be no doubt and the success of the treatment, it seemed to me, depended in very large measure upon the fact that they were regarded as a peculiar form of malaria and received quinine.

The hæmaturia which was present in four of the cases deserves more than simple mention. Davidson<sup>1</sup> speaks of hæmorrhages and spongy gums as sometimes met with in the relapsing fever of Cyprus—the spongy gums, he will remember, in cases of genuine relapsing fever, where scorbutus was out of the question. Many of these cases, however, were attributed by Davidson to malarial poisoning. Hirsch<sup>2</sup> draws attention to the Danubian basin as the seat of malaria. At certain places along the river malaria, it would appear, is always endemic. In what is called "remittent" malarial fever there is hæmaturia and in some instances jaundice. Besides, there is another form of malarial fever—the typho-malarial. It occurred among the American troops during the War of Secession. Woodward, whilst stationed with the army on the Potomac, noticed the peculiar form which malarial poisoning assumed amongst the soldiers, and drew attention to a series of symptoms not unlike those met with in typhoid fever—viz., diarrhoea, abdominal tenderness, meteorism, delirium and dry brown tongue. The cases did well as a rule when treated by quinine. In the few that died post-mortem examination showed only a catarrhal condition of the mucous membrane of the intestine with swelling of Peyer's patches. The spleen was enlarged to a greater extent than in typhoid fever; so also was the liver. His description of the disease might apply to some of my own cases, but in using the term typho-malaria we would be now, as then, no nearer a solution of the question. It is quite possible that impure drinking water induced illness and developed symptoms of an enteric type, upon which was grafted malarial infection. I am more inclined to regard these cases, however, as simply hæmorrhagic forms of malarial poisoning, there having been in nearly all of them blood in the urine and stools, and in one spongy gums. This is just the form of malarial poisoning in which we may or may not have typical ague seizures. Febrile exacerbations may not occur, and yet malarial hæmaturia in certain localities and in certain seasons of the year may be so severe as to prove fatal.

Newcastle-on-Tyne.

## THE SKIN ERUPTIONS WHICH OCCUR IN SEPTICÆMIA FOLLOWING SCARLET FEVER AND DIPHThERIA.

BY N. S. MANNING, F.R.C.S. IRELAND,  
MEDICAL SUPERINTENDENT OF THE CITY HOSPITAL, BIRMINGHAM.

IN 2.1 per cent. of nearly 6000 cases of scarlet fever and diphtheria treated under my care in the City Hospital, Birmingham; and in 4.8 per cent. of the cases under five years of age a condition supervened which was accompanied by a characteristic skin eruption, increase of temperature, wasting of the tissues and loss of power, and which, on account of the high mortality that followed it, may well be considered one of the most important complications that can become superadded to these diseases. The exciting cause of the condition or disease appeared to be the absorption into the system of a toxic agent or poison which was engendered by tissue necrosis taking place in septic surroundings; and though in the cases at present under consideration it followed the process of ulceration which took place in the throat, nose and nasal cavity in scarlet fever and diphtheria, it may also be brought about by many other conditions, such as sloughing

<sup>1</sup> Geograph. Pathol., vol. i., p. 206.

<sup>2</sup> Geograph. Pathol., vol. i., p. 210 (New Sydenham Society).

and suppurating burns or other wounds, in the puerperal state, in the third week of enteric fever, or, broadly speaking, by purulent infection from any cause. The following figures show in a tabular form some particulars as to the numbers, ages and mortality in the cases under notice.

Age.	Total number of cases treated in the hospital.	Number of cases of septic rash that occurred.	Number of deaths.	Percentage occurrence on the total numbers treated.	Percentage mortality of the cases attacked.
Under 1 year .. ..	64	12	11	10.0	91.6
"  2 years .. ..	391	41	35	10.4	85.3
"  3  "  " .. ..	587	33	27	5.6	81.8
"  4  "  " .. ..	577	15	14	2.6	93.3
"  5  "  " .. ..	671	9	3	1.3	33.3
Total under 5 years	2200	110	90	4.8	81.8
5 years and upwards	3022	18	12	0.5	66.6
Total .. ..	5912	128	102	2.1	79.6

As will be seen in the above table the age of the patient exerted the most powerful predisposing cause in determining the disease; nearly 60 per cent. of the cases were under three years old. The reason of this is very obvious when we consider how difficult it is to keep the throat lesions in patients of such tender years in anything like an aseptic condition, and how prone they are to swallow the discharge that exudes from the ulcerated surfaces. The attack came on usually during the second week of the scarlet fever illness; in 80 per cent. of the total cases it was noticed from the seventh to the fifteenth day, but it may appear as early as the fifth day or as late as the thirtieth. The invasion was gradual rather than sudden, and in many cases was even insidious in its onset. As a rule, however, in severe cases from twelve to twenty-four hours before the eruption came out there was an increase of temperature, with restlessness, sleeplessness, and an exacerbation of the throat lesions. The eruption appeared as red or dark pink coloured spots or blotches with well-defined margins in the skin over prominent bony points, such as the ankles, finger-joints, elbows, outer sides of the feet, and the extensor surfaces of the toes; occasionally a crop of small red papules on the arms and legs preceded the blotches. The spots or blotches when first seen varied in different cases from about the size of a sixpenny piece to large irregular-shaped patches; they disappeared on pressure and quickly reappeared when the pressure was removed. In about 80 per cent. of the cases the eruption appeared in the order given above, but sometimes it was first seen on the face, in which situation the most usual distribution was the upper eyelids and malar eminences. I might remark here that I have found this distribution of the rash so uniform in its early stages and so characteristic of the disease that in cases where I suspect its occurrence I look most carefully in these situations for its existence.

In many cases, after the appearance of the rash, what seemed a halt in the progress of the disease took place; no manifest change occurred for some days or the spots faded and again appeared, and in some slight cases the disappearance was permanent. In severe cases this check, as a rule, was not seen. The rash extended rapidly over the limbs, in some instances as large irregular-shaped maculæ, red or pinkish in colour and slightly raised above the level of the skin; in others in the form of diffuse patches of various shapes and sizes. It usually invaded the trunk on the second or third day from its first appearance, in which situation the macular or blotched form was replaced by a diffuse erythema. About this period of the eruption—second or third day—it also became diffuse on the limbs by the rapid increase in size and confluence of the spots. In a less numerous class of cases the eruption remained macular for a longer period; but if the attack were severe and the patient survived long enough, the tendency always was for the rash to become general. The time which the eruption took in reaching its maximum point of development is thus seen to have varied considerably in different cases, and when this was attained a decline or fading took place, which was followed by a profuse desquamation of the cuticle; this subsidence, scarcely ever permanent, was quickly followed by a recrudescence; the temperature, which usually declined with the fading of the rash, again went up, and in from twelve to twenty-four hours

a second eruption came out, which more rapidly than the former spread over the body. There was also an aggravation of all the local and general symptoms, and the cycle was completed by another desquamation of the cuticle. In this way I have been able to raise three distinct parchment-like layers of the epidermis on the hypothenar eminence of a child's hand which could be turned over like the leaves of a book—(1) scarlet fever desquamation, (2) septic fever, (3) relapse of septic fever.

The temperature was essentially irregular and was seen to vary much in different cases. Usually, however, the temperature curve was within the limits of from 100° to 104° F., but even in the same case the extreme limits often varied from 98° to 105°; the diurnally up and down or "spiked" temperature seen in enteric fever or hectic conditions was never observed. As already mentioned, a defervescence took place in many cases with the decline of the rash, which was followed by a rise before each recrudescence, and at this point, which one might term the invasion of the relapse, death frequently occurred. The heart's action was rapid, beating from 130 to 200 per minute. Nervous disturbance indicated by such symptoms as restlessness, sleeplessness and muscular tremors was commonly met with, and in some instances marked drowsiness prevailed. The progress of the disease was always accompanied by rapid wasting, in a few days the sufferers presenting quite an emaciated appearance. In cases where the urine could be obtained for examination albumen was sometimes found. Septic pneumonia, diarrhoea, or obstinate vomiting frequently supervened where the patient survived beyond four or five days, and rapidly proved fatal. To the welfare of the patient the condition of the throat was most important all through the attack; the ulceration spread over the tonsils, pillars of the fauces, pharynx and soft palate, and in many cases to the tongue and gums, engaging the deep tissues in the region of the throat, and often producing large ragged perforations of the soft palate. There was also a profuse discharge of muco-pus from the throat and nostrils and a foul-smelling colourless otorrhoea. In fatal cases, as the end approached, the secretions of the mouth dried up, sordes formed on the teeth, the tongue became glazed, the lips cracked and bled on the slightest touch; there was also suffusion of the conjunctive and more or less fixation of the eyeballs, which gave the eyes a staring expression, the patient finally lapsing into a marked ataxic condition. When this stage was reached the sufferers presented a very repulsive appearance and in addition a sickly odour pervaded their immediate vicinity. The duration of the attack varied greatly, the extremes in fatal cases being from two to thirty days; but between 70 and 80 per cent. died during the first week. In non-fatal cases the eruption disappeared in over 80 per cent. within five days, in 15 per cent. from five to ten days; in one case it remained until the fourteenth and in another until the twenty-second day. The most constant morbid appearance found post mortem was an inflammatory zone one or two lines wide round the attached margin of the mitral and tricuspid valves of the heart; in this situation in many cases the endocardium was found thickened and injected. The post-mortem coagulation of the blood seemed to take place in a normal way. More or less congestion of the lungs was seen in every case, and in cases where pneumonia was present the anatomical appearances of that disease were found; the kidneys also were usually congested and, where microscopic examination was made, "cloudy swelling" was seen. In the other organs no changes were noticed.

The treatment may be divided into prophylactic and curative. In the former much can be done by careful attention to the state of the throat; the removal of the exciting cause by keeping the ulcerated parts in as clean and aseptic a condition as possible is all important. This, in my experience, can best be attained by irrigation. The use of caustics or other irritants during the inflammatory stage cannot be too strongly deprecated. Healthy surroundings, proper diet and good nursing are of course most essential. In the way of curative treatment little can be done except to follow up the lines already indicated and support the patient's strength by every means possible. The administration of drugs, except for the relief of special symptoms, I have not seen attended with any beneficial results.

The question of diagnosis is most important, but want of space prohibits me going into the subject fully. The disease with which this condition is most frequently confounded is scarlet fever, and indeed its occurrence even during an attack of this exanthem is regarded by most authorities as a relapse of the disease. The invasion, the distribution of the rashes in

the early stage and the course which the two diseases run are so entirely different that a diagnosis is easily made; moreover, in cases that arise in the course of other diseases, in addition to the differences just stated, there is an absence of the throat lesion and that characteristic condition of the tongue—signs that should guide us almost more than any other in determining an attack of scarlet fever. There is no doubt but that the eruption, when fully developed, resembling so closely as it does the intense or blotched rashes often seen in scarlet fever, and the subsequent desquamation combine to render a correct diagnosis difficult if the primary symptoms have not been carefully observed. It is also confounded with measles, röteln, eruptions produced by drugs, urticaria, crupelias, &c., and although the rash sometimes resembles that of measles and röteln, by careful attention to the invasion, the early distribution of the eruption, and the absence of the catarrhal symptoms found in these diseases—more especially measles—it is always easy to arrive at a correct diagnosis. In the other conditions named the differences are so many and so manifest that a diagnosis should present no difficulty.

Birmingham.

## TWO CASES OF RETRO-PHARYNGEAL ABSCESS IN INFANTS.

By W. F. BROOK, F.R.C.S. ENG.

THE notes of the following two cases may be of interest, as they not only closely resemble the cases which form the basis of Mr. Bilton Pollard's paper on the above subject in THE LANCET of Feb. 13th, but also bear out his remarks as to their etiology and treatment. I believe I am right in saying that these were the only two cases of the kind which presented themselves at the Hospital for Sick Children, Great Ormond-street, during the fourteen months that I was house surgeon there.

The first case—M. G—, a female child aged one year and seven months—was brought to the hospital on Oct. 13th, 1890, suffering from difficulty of breathing and swallowing and a "lump" in the neck. The history given was that a swelling had been noticed in the neck a fortnight previously, which gradually increased in size. Breathing and swallowing became difficult and continued to get worse until admission. She had had whooping-cough the previous February, since which she had suffered from discharge from the nose. There had been no pain or stiffness in the neck before the swelling was noticed. Four months previously she fell from a chair, striking her head. On examination, in the right side of the neck was a diffuse non-fluctuating swelling, situated behind but extending under the sterno-mastoid and pushing it and the carotids forwards, with a more defined lump in the centre, apparently a gland rendered prominent by the subjacent swelling. The right tonsil was seen to be pushed towards and beyond the mid line, obscuring the view of the parts beyond. Chloroform was given, with a view to making a more thorough examination and doing what might be required. A gag was introduced into the mouth for the more complete examination of the pharynx, when the breathing suddenly stopped, the child becoming cyanosed. The trachea was immediately opened and the patient brought quickly round by artificial respiration. With the tube in the trachea, the swelling in the pharynx could be examined at leisure. It extended from the right tonsil across the back of the pharynx nearly to the left. Its upper limit was at the base of the skull, its lower limit below the level of the glottis. It was so tense that fluctuation could barely be made out. Although, had the abscess been opened from the pharynx, the presence of the tracheotomy tube would have removed the danger of asphyxia, the impossibility of keeping the cavity aseptic under these conditions led me to prefer to drain it from the neck. Accordingly a small incision was made along the posterior border of the sterno-mastoid and the dissection continued beneath it until a wave of impulse could be distinctly felt between a finger at the bottom of the hole thus made and another on the swelling in the pharynx. With a blunt director and a pair of dressing forceps the abscess was then speedily emptied, the swelling in the pharynx at once subsiding. No bare bone could be felt by the finger introduced into the abscess cavity. The latter was washed out with perchloride of mercury (1 in 2000), a drainage tube introduced, and the incision closed at

the ends with sutures. The tracheotomy tube was removed and the wound sutured also. The breathing was now in every respect normal. The temperature, which on admission was 98·8°, on three occasions within the next few days reached 100° F. With a view to keeping the injured parts at rest the patient was fed for the first twenty-four hours per rectum. The discharge from the wound in the neck was slight and the tube was gradually shortened and removed entirely on the seventh day. The tracheotomy wound did not heal by first intention, but gave no trouble. The child was discharged on Nov. 3rd, with both wounds healed and no sign of spinal caries.

The second case was that of W. L—, a male child aged six months. He had been ill a fortnight with a "swelling in the neck and wheezing." There had been a slight discharge from the nose during the previous week, but not any discharge from the ear. The history did not suggest spinal caries or syphilis, but there was a history of phthisis on the father's side. On admission on Dec. 23rd, 1890, the notes describe him as an emaciated and rickety child, breathing with some effort. The crying was feeble. There was retraction of the lower ribs and to a less degree above the clavicles. In the neck on the left side was a fluctuating swelling beneath the sterno-mastoid. In the upper part of the pharynx, on the left side, was a fluctuating swelling extending up behind the soft palate and across the middle line. As the sterno-mastoid muscle seemed unusually wide and thin and pus was evidently immediately beneath it, I opened the abscess by a small vertical incision through the muscle. The finger introduced through the opening passed behind the carotid sheath and the pharynx beyond the middle line, and could feel the base of the skull above. There was no bare bone to be felt. An inch and a half of small drainage-tube was inserted and the cavity washed out with perchloride of mercury (1 in 2000). Immediately after opening the abscess breathing was relieved and the cry became stronger. In three days' time the tube was removed and the child was discharged on Jan. 4th, 1891.

In both these cases there was a history of irritation and inflammation of the nasal or naso-pharyngeal mucous membranes, and in neither was the abscess associated with cervical caries or of tonsillar origin. The analogy between this form of retro-pharyngeal abscess and subacute or chronic ischio-rectal abscess so common in feeble and cachectic subjects is very striking. Both occur in weakly and debilitated individuals and seem to result from apparently slight irritation of the adjacent mucous membranes, and in each case, too, it is in the submucous tissue that the suppuration occurs and not in glands (or at all events those demonstrated in naked-eye anatomy) which drain the corresponding area of mucous membrane.

The above cases were under the care of Mr. Morgan and Mr. Owen respectively, to whom I am indebted for permission to publish them.

Swansea, S. Wales.

## ANGEIO-LEUCITIS AND DEATH FROM INFECTION BY MICRO-ORGANISMS DERIVED FROM THE ADHESIVE SURFACE OF BUNION PLASTER.

By A. S. MYRLE, M.D. EDIN.

Mrs. —, aged forty-nine, enjoyed good health and led an active out-door life since childhood; regular in all functions; she had seven children, the youngest being aged thirteen. About the 16th of May, to protect a bunion on the right foot, she applied a felt plaster; this was worn for a fortnight, when the bunion got red and painful, and a small ulcer was found on the great toe, where the hardened gelatine had worked its way through the skin. The sore was a quarter by one-eighth of an inch. About the end of May she felt "seedy," listless and nervous; her appetite had failed, and her nights were disturbed. She then consulted me. I found her, as I thought, very much below par; she was worrying herself about going to the Continent. I advised her to remain at home and prescribed a tonic, and, as the bunion was inflamed and painful, ordered lead and opium lotion. The ulcer, which looked sluggish and void of healthy granulations, I covered with iodoform and salicylic cotton-wool, and ordered the foot to be kept at rest.

On June 6th my son saw her. She complained of pain in the centre of the right patella, slight pain and swelling on the inside of the left wrist, and pain in the palmar aspect, first phalanx, of the forefinger of the left hand. She looked and felt ill, but there was no constitutional disturbance and the temperature, pulse and functions were normal. He thought the symptoms indicated either rheumatism or gout as their cause. He saw her again on the 7th; the symptoms were then unchanged. On the 8th I visited her and could discover nothing fresh. I inquired about the sanitary condition of her surroundings, and these were thought to be perfect, but she admitted she had felt that the stable in which some pet ponies were kept was in a most vile state and that the stench, when she had been there for ten minutes, almost made her sick. On the 12th she came to Harrogate. She was much exhausted by the long drive and complained of severe pain in various groups of muscles, in the calves, the soles of the feet, the hips and intercostal muscles on the right side. Pulse 72; temperature 98.5°. Any attempt at movement aggravated pain; and on the 14th this was so great that she took to her bed. On closer examination I found the lower extremities much wasted. I could almost wrap the skin of the calf round the shin-bone. This I attributed to trophic nerve disturbance. She was able to take food well. As the ulcer was still unhealed I applied creolin lotion. On the 17th the ulcer had healed, but the nurse called my attention to a slight redness on the left great toe and the dorsum of the foot; this was clearly erysipelatos; and on examining the leg I found it greatly swollen, the skin cool but tense, the swelling, elastic and involving the whole leg and thigh, did not pit on pressure. I told the patient she had what is usually called a white leg, and that I had never met with such a case.—18th: Pains more severe than ever.—19th: Much the same.—20th: Slight erysipelas on the back of the left thigh; pulse and temperature normal; taking plenty of nourishment, with brandy and champagne.—21st: Patient worse. I called Dr. Eddison of Leeds in consultation, but told him nothing, as I wished to have his own opinion unbiased by mine. He examined her most carefully, got her out of bed, but as soon as her feet touched the ground the pain was so severe we had to put her back. Dr. Eddison admitted he had never seen or read of such a case. He saw her again on the 22nd, when she was in much the same condition. As to treatment, excepting morphia hypodermically, nothing proved of the slightest use.—30th: The upper and posterior left thigh looked as if pus was forming, the erysipelas had extended, and I put her on solution of perchloride of iron, chlorate of potash and boric acid, and wired for Mr. Jessop, as I wished for a surgical opinion. At 4.30 he saw her, pronounced the case to be one of inflammation of the lymphatics, and thought it most critical.—July 1st: All pain gone from the left limb; also erysipelas abated; but pain and swelling in the right thigh had developed; pulse 84; temperature 100°. I doubled the amount of brandy and continued the iron mixture and morphia.—2nd: Mr. Jessop came again; everything seemed to be going on as favourably as we could expect, so much so that he proposed to meet me on the 4th.—3rd: She had passed a restless night and rambled slightly; still she took plenty of nourishment; pulse 90; temperature 100.3°. At 8 p.m. I found her in the same state, and administered the usual dose of morphia; at 10 she took soup and brandy. At 12 I was called and found her dying. She died ten minutes after my arrival.

What puzzled me was the severity of the pain, the suddenness of its attacks and the total absence of heat, swelling, inflammation or constitutional disturbance. I looked on it as acute neuralgia. Until June 17th there was no local change, and then the mischief showed itself not in the leg where the ulcer had been but in the other. Before coming to any conclusion as to the cause of death I had all the drains of the dwelling-house, out-houses and stables thoroughly examined by Mr. Slater, sanitary engineer, Leeds. He sent me a full report, and added: "In conclusion there appears to be no serious sanitary defect in the system of drainage," which is borne out by the fact that all the inmates of a very large establishment and even the stablemen, who spent hours in the ponies' stable, were in good health. Blood-poisoning we had here without doubt, and I am driven to the conclusion that some pathogenic micro-organisms buried in the gelatine took possession of the denuded surface and so infected my patient. Considering that all sorts of animal refuse are made use of in the manufacture of glues &c.—diseased hoofs, horns, parings of hides &c.—

the wonder is that more cases of infection by such germs have not been met with, and if I am right in my view, a Government inspector should be appointed, so as to prevent the utilisation of diseased animal refuse in the production of articles of commerce which must be brought into contact not only with the skins, but with the lips and mucous membranes of all classes of the community.

Harrogate.

## THE PLACE OF ANTHROPOLOGY IN MEDICAL EDUCATION.

By HAVELOCK ELLIS, L.S.A.

VIROHOW, who adds to his other claims to fame that of being the first of living anthropologists, has recently confessed that his attention was directed to the science of anthropology by the difficulties he encountered in the study of the insane. Charcot, again, frequently impresses on his pupils the importance of studying the healthy nude, and of an acquaintance with anthropometric canons, as an aid to the diagnosis of abnormal conditions. These utterances of two of the most honoured of our teachers in very different fields suggest that there is a defect in our medical courses, as they exist at present in England, which demands, at the least, some consideration. As evidence of the close relationship between anthropology and medical practice, it is enough to mention that in spite of the difficulties we at present place in the way, with a few exceptions (in which zoology alone led up to anthropology), the chief anthropologists of the last half century have been medical men—in not a few cases very distinguished in the profession; at the least, they have started as students of medicine. It is sufficient to mention in France Broca, Topinard, Lacassagne, Manouvrier, Collignon and Letourneau; in Germany, around and below Virchow, Ranke, Schaeffhausen, Ploss, Bartels and many others; in Italy, Mantegazza, Lombroso, Sergi; in our own country, Galton, Beddoe, Sir Wm. Turner, Flower and Garson, while to a somewhat earlier period belong the great names of Prichard and Thurnam. While every medical man would find a slight acquaintance with anthropology some help in practice, there are certain branches of practice in which some knowledge of anthropology is of especial assistance; for example, practice abroad and asylum practice. No country sends out so large a body of medical men into all parts of the world, but the amount of scientific work done among the races of our great empire by these men is so small that it is scarcely perceptible. French medical men have done far more for their few colonies, and the medico-legal and anthropological studies which have come from the Lyons school, under the inspiring influence of Lacassagne, are especially worthy of honour.

What is true generally of the English medical man abroad is equally true of the English alienist at home, and must be so, since the study of anthropology is largely the study of the manifestations of the brain and nervous systems. In the practical treatment of the insane England stands before every other country; in the scientific study of the insane no leading country is so backward. Elsewhere the exact study of madness is making rapid progress; it is beginning to be recognised that the great truth that knowledge means measurement (*scire est mensurare*) fully applies to the brain and nervous system. But in this country the rule-of-thumb method still reigns nearly everywhere. In the hands of a master in psychiatry the rule-of-thumb method more often than not leads to perfectly reliable conclusions as to the mental status and condition of the subject before him, but it has two obvious disadvantages: it can only be trusted in the hands of a master; while even a master's mere impressions, however trustworthy, add nothing to the common stock of scientific knowledge. In actual practice, with our present knowledge of neurology, it is becoming a great advantage to the alienist to be able to demonstrate that his subject is twisted in anatomical structure and perverted in physiological action; while, so far as science is concerned, in the end it is only accurate observation that counts.

All that can be said as to the state of psychiatry generally in England applies in even a stronger degree to that special branch of it which deals with the criminal. During a period of nearly twenty years no contribution to criminal anthropology of any value appeared in this country, and although of late there may be said to have been some revival of the science among us, it is still in an infantile stage. Of this a striking proof is furnished by the non-appearance of English representatives at the International Congresses of Criminal Anthropology, which have been attended by delegates from all parts of the world. Maudsley and others have, indeed, preached concerning the desirability of an exact study of criminals; but while in Italy Lombroso, Marro, Ottolenghi and Rossi have alone examined according to modern scientific methods over 3000 criminals, English alienists have been content to leave the first tentative practical efforts to a prison chaplain. It would, however, be unjust to put this down merely to apathy. It is largely due to ignorance. My own extensive correspondence with prison surgeons (as well as with medical officers of asylums) has shown that they often possess genuine scientific interest in the phenomena presented to them, but that they do not know how to observe rightly and record the facts that come before them and would gladly receive hints that would enable them to bring forward results of value to scientific medicine. It should be part of the business of medical education to give these hints.

We are often told that the medical student of to-day is overburdened with study; and, although it must be remembered that the period of his studies is now being enlarged, there is no doubt truth in this statement. It becomes the more necessary, on the one hand, to place in a period antecedent to medical studies proper the preliminary scientific courses; and, on the other hand, to cut away without remorse those branches of knowledge which have ceased to possess any close connexion with modern medicine. In certain directions it is probable that the studies of medical students might with advantage be abbreviated or rendered optional. The study of botany, however valuable and fascinating, no longer possesses any special advantage as a preparation for medical practice, now that the physician is very clearly differentiated from the herbalist and "medical botanist." An exact knowledge of the pharmacopœia also, which once embraced almost the largest part of the doctor's work, may now safely be left to the medical antiquarian. If it is necessary to make room for anthropology by the omission or contraction of other preliminary courses, it is not difficult to put one's finger on studies which for the student of medicine have come to possess a value which is merely traditional.

The point at which anthropology comes into medical study is very clear. Human anatomy and comparative anatomy both lead directly up to it. The study of human anatomy we cannot afford to contract. The comparative anatomy course, however, might well be arranged so as to afford a general view of the province of anthropology, while passing lightly over those earlier stages of animal life which have less concern for the medical man. With these lectures should be associated a brief course of practical demonstrations. We can scarcely expect at present that individual medical schools should be at the expense of fitting up laboratories of physical anthropology. This point would be much simplified if the excellent suggestion of Sir Andrew Clark was adopted—namely, that there should be a common centre for the teaching of the non-medical branches of medical education. In the meanwhile there are existing centres which by arrangement might no doubt be utilised. There is Galton's Anthropometric Laboratory in active operation; there is the Anthropological Institute, which might become a centre of work; and, above all, there is the Museum of the College of Surgeons, so rich in objects of anthropological interest, and which has not seldom been presided over by eminent anthropologists.

The time seems to have come when some small preliminary step in the direction here indicated should at length be taken. In Paris the anthropological Musée Broca, with its active laboratory and the anthropological school, has long formed part, as it were, of the medical schools. It is not necessary for the medical man of to-day to know much of the lower animal forms; still less necessary is it that he should have any thorough knowledge of plants. But it is increasingly necessary that he should understand the science of man.

St. Mary's-terrace, Paddington W

## THE TREATMENT OF FILARIA SANGUINIS HOMINIS.

BY SURGEON-LIEUTENANT-COLONEL A. CROMBIE, M.D. ED.,  
SURGEON-SUPERINTENDENT, GENERAL HOSPITAL, CALCUTTA.

IN the beginning of 1891 Surgeon-Lieutenant-Colonel E. Lawrie<sup>1</sup> reported two cases of filaria sanguinis hominis, in which the immature parasites disappeared from the blood under the use of thymol internally; and in December of the same year Dr. Walsh<sup>2</sup> of the General Hospital, Calcutta, recounted a case of chyluria in which they disappeared from the urine under the same treatment. Surgeon-Lieutenant-Colonel Lawrie gave one grain, and after a fortnight two grains, of thymol every four hours in one case, and two grains, increased to five grains, thrice daily in the other case; and after two and one month's treatment respectively the filaria could no longer be found. Dr. Walsh followed the treatment adopted in Surgeon-Lieutenant-Colonel Lawrie's second case, and in a fortnight the urine became clear and no filaria could be found in it.

I have recently given this drug in two cases. The first was a young man aged eighteen years, who was sent into hospital for lymphatic varix of the left spermatic cord. A history of periodic fortnightly fever, with lumbar pain accompanying the spermatic enlargement and a recent phlebitis affecting the left basilic vein, led me to suspect that he was infested with the filaria, and three immature worms were found in one preparation of his blood. I began by giving him on Feb. 2nd 5 grains of thymol thrice daily and rapidly increased the dose till on the 18th he was taking 200 grains daily, and this dose he took on Feb. 18th, 19th and 20th. The blood was examined every second or third night, and on the night of the 20th there were seven active and lively worms under one cover-glass. This large dose of thymol produced little or no effect on the patient beyond a little giddiness occasionally during the three days on which he took 200 grains daily.

Another patient, aged sixty-seven, of no occupation, who had resided fifty years in India, was admitted on Dec. 7th, 1891, with a contused wound of the scalp and an old-standing anterior curvature of the spine. Towards the end of February she had fever, accompanied by pain and swelling of the right leg, and on the blood being examined it was found to contain the filaria sanguinis hominis, about four to each drop. The treatment with thymol was begun on the 14th of March in doses of 5 grains thrice daily, rapidly run up to 15 grains four times a day. These doses produced a sensation of heat down the track of the œsophagus after taking the medicine, but she could take 45 grains daily without inconvenience. After a fortnight's treatment the filariæ were found in considerable numbers and very active.

It is evident that in neither of these cases did the thymol, even when pressed to the limit of toleration, have any effect on the filaria. Thymol is so exceedingly insoluble that it is improbable that any appreciable quantity of it left the intestinal canal. As an intestinal anthelmintic I have the very highest opinion of thymol, using it with the greatest success in tapeworm as well as against the smaller worms of the bowel, but I am afraid we must abandon the hope that we had found in thymol a cure for the parasites of the blood. The second patient submitted herself for treatment with other drugs, and she was given in succession for a fortnight at a time the following:—Two minims of creosote three times a day; 2 minims of benzol, gradually increased to 5 minims, three times a day; 2 minims of guaiacol, increased to 5 minims, three times a day; and, lastly, 5 grains of gallic acid, increased to 10 grains, thrice daily, but at the time of writing the nematodes are as numerous and lively as ever.

Calcutta.

<sup>1</sup> THE LANCET, Feb. 14th, 1891.

<sup>2</sup> Indian Medical Gazette, December, 1891.

THE SEWAGE OF HALIFAX, YORKS.—A report has been issued by the borough engineer of a scheme for dealing with the town sewage at SALTERHEBBLE. It is proposed to construct settling and precipitation tanks, also sludge filter beds, and to chemically treat the sewage. The entire estimated cost is £19,683.

ROYAL FREE HOSPITAL.

PRIMARY TUBERCULOUS ULCERATION OF LARGE INTESTINE.

(Under the care of Dr. SAINSBURY.)

W. E—, aged nineteen, brass finisher, was admitted into the Royal Free Hospital on Oct. 28th, 1890, suffering from diarrhoea. On his father's side the family history was good, but three relatives of his mother had died of "consumption." He has never been very strong, but up till about thirteen years of age he had been fairly well. Ever since then he has been subject to attacks of diarrhoea and abdominal pain, accompanied by giddiness and frontal headache. These attacks vary in length, lasting from one to two weeks. The motions have been generally light, and have never been mixed with blood. These attacks have recurred at varying intervals, but the longest interval has been only six weeks. He has also been subject to a cough, especially troublesome in the morning, and markedly worse in the winter; there was much expectoration, but never any blood. A fortnight before admission an especially severe attack of diarrhoea occurred, with pain in the abdomen, headache, chiefly frontal, giddiness and flushes of heat and cold. The abdominal pain had for the most part been diffused, but occasionally it had been located in the right iliac region. The diarrhoea had continued up to admission and for the last week the patient had been confined to bed. On admission the patient was small for his age and looked by no means strong. His lips and nails were distinctly bluish; pulse 120; respiration 39; temperature at 6 P.M. 102°. The appetite was bad and the tongue furred. He complained of pain in the abdomen, especially in the right iliac fossa. The bowels acted generally twice a day; the stools were liquid but normal in colour. There was no abdominal tenderness. Neither liver nor spleen could be felt. Sibilant râles could be heard all over the chest, but nothing else abnormal could be found. The cough was somewhat troublesome. The urine was rather scanty, but contained no albumen or sugar. The patient was put on a diet of three pints of milk, and given a simple linctus for the cough.

Oct. 29th.—He has had a bad night, the cough disturbing him greatly. He has passed two liquid stools. The temperature fell this morning to 97°, but has risen again this afternoon. The pulse is markedly dicrotic.

Nov. 2nd.—He complains of some sharp pains in the right iliac region in addition to the previous dull pain there. His temperature rises every evening to 102° or even 104°, obtaining the maximum about 6 P.M., and falls the next morning to below 98°, with profuse sweating.

8th.—No marked change in his condition. He still sleeps badly, the cough being troublesome. The daily variations of temperature still continue. Some beef-tea is added to the diet.

18th.—The temperature did not rise above 100.5° for two days, but has since resumed its former course.

24th.—An enema of oil of turpentine in thin gruel was administered. The diarrhoea continues, and on the 27th five minims of tincture of opium were given every four hours, but it seemed to have but little effect on the diarrhoea.

Dec. 5th.—His right ear commenced to discharge slightly on Dec. 1st. This continues. To his milk diet have been added some eggs, milk pudding, and bread, and two ounces of pounded meat. As the diarrhoea was still very troublesome, he was ordered ten minims of aromatic sulphuric acid in an ounce of decoction of logwood.

6th.—He feels better for the solid food, though the diarrhoea is rather worse. The daily variations of temperature still continue, but are of smaller extent. Ordered five grains of compound ipecacuanha powder and ten grains of compound kino powder, three times a day.

9th.—The diarrhoea still continues. He was put on a diet of milk and eggs again, and an enema was given twice a

day of two grains of sulphate of copper and twenty minims of tincture of opium in four ounces of mucilage of starch.

11th.—The enema seemed to have had no effect on the diarrhoea, so it was discontinued, and five grains of lead and opium pill were given, and turpentine stupes ordered to the abdomen.

28th.—On Dec. 12th the temperature fell to normal, and has remained so, except for two temporary rises, until now. The diarrhoea has diminished in frequency and the general condition of the patient has much improved; but to-day the diarrhoea was again troublesome, and he was ordered five minims of castor oil and five minims of tincture of opium to half an ounce of camphor water every hour.

29th.—The diarrhoea is decidedly better, but the temperature has risen to 103°. As the medicine seemed to cause nausea, it was stopped.

Jan 12th, 1891.—The diarrhoea varies greatly in severity from day to day. The patient is very tired of milk diet, and so has been given some eggs and milk pudding.

15th.—The patient complains that his throat is very sore, and that swallowing is painful and difficult. His cough still continues, but nothing abnormal can be detected in the chest. His general condition is worse. He was ordered essence of beef and three ounces of brandy a day.

20th.—The diarrhoea still continuing, the patient was ordered one drachm of liquid extract of bacl and ten minims of liquid extract of opium three times a day.

21st.—Slight hæmorrhage appeared in the stools to-day. An enema of ten grains of nitrate of silver in four ounces of mucilage of starch was ordered. The diarrhoea is increasing in frequency, the bowels acting seven or eight times a day. He has been ordered subnitrate of bismuth with opium and kino.

30th.—He is certainly better and the diarrhoea has diminished. The throat continues to be sore.

The patient's general condition did not materially alter until May 15th. At times he was well enough to get up for some hours. The diarrhoea continued, the bowels acting from six to eight times a day. The cough was all the while troublesome, but there was little sputum.

The temperature from Jan. 18th remained about normal until death; there were indeed occasional rises to 100° or a little more, but these were at long intervals. He slowly wasted. On May 16th he was seized with severe pain in the left axilla, but on examination no adventitious sounds could be heard. Œdema, especially of the left foot, came on. On May 19th he had severe dyspnoea in the early morning, was unable to take any food, and died the same evening.

At the post-mortem examination the left pleural cavity was found to contain about half a pint of serous effusion and the parietal and visceral surfaces of the pleura were coated with recent lymph. The right lung, except just at the apex, was extensively invaded by small caseous masses, most marked on the surface. In the lower part of the upper lobe was an irregular cavity with very offensive contents; in the lower lobe was a patch, solid from catarrhal pneumonia and tuberculous infiltration. Patches of catarrhal pneumonia were found in many parts of this lung. The left lung was also extensively diseased, the only free part being the apex. A large irregular cavity existed in the lower part of the upper lobe, with offensive contents. The lower lobe was almost solid with catarrhal pneumonia, but numerous caseous tuberculous masses also existed. The heart was small. The liver showed venous congestion. The large intestine, from cæcum to rectum, had its walls much thickened and very extensively ulcerated. Many of the ulcers were large and deep, with overhanging edges. A considerable number of small abscesses existed in the wall of the bowel. The small intestine only exhibited a few tuberculous ulcers, notably two near the ileo-cæcal valve. The œsophagus was ulcerated for a length of about three inches, beginning half an inch from the cricoid cartilage. The other organs were normal and showed no tubercles.

*Remarks.*—The case here recorded is of interest for the following reasons: 1. The frequent recurrence during six years of attacks of diarrhoea and abdominal pain. 2. The marked, but irregular, pyrexia which for more than two months accompanied the attack for which the patient was admitted into hospital. 3. The essentially abdominal characters of this attack, which were such that, in spite of the irregularity of the pyrexia, it was difficult during the earlier stages to exclude typhoid fever. 4. The absence of any definite signs in the chest, though this was frequently examined. Reviewing the whole case, though it must be

admitted that it is often difficult to estimate the relative ages of tuberculous lesions of different parts of the body, yet the evidence here is strongly in favour of a primary intestinal tuberculosis, with secondary implication of the lungs. It will be noted that both lungs, though extensively diseased, were free or nearly free at their apices; also that in the rest of the lungs the foci, though numerous, were very scattered. The question arises of what nature were the preceding attacks of diarrhoea—tuberculous or simple?

### NORTH RIDING INFIRMARY.

PNEUMOTHORAX.—TUMOUR (FIBRO-ADENOMA) OF THE MALE MAMMA.

(Under the care of Dr. MUNRO.)

WE publish the following account of a case of pneumothorax, as the question of treatment is being discussed in the correspondence columns of THE LANCET. The course of such a case is usually as described below—a feeling of something giving way, sudden severe pain and difficulty of breathing, and the abnormal physical signs in the chest on the side affected, with displacement of the heart, and the cause, tuberculous disease of the lung, the most common one. Treatment by aspiration again failed to give relief. For the notes we are indebted to Mr. G. Victor Millar, resident surgeon.

CASE 1.—R. H.—aged twenty-four, seaman, was brought to the North Riding Infirmary on April 20th, 1892, suffering from severe pain in the left side of the chest and great difficulty of breathing. The patient had a somewhat cyanotic appearance, the face wore an anxious expression, and he looked like a person suffering from pneumonia of several days' standing. He stated that three days previously, whilst standing quietly on the deck of his ship, he felt something give way in his left side and was suddenly seized with severe pain, of a stabbing character, in that region, and with great difficulty of breathing. He said he had suffered from a cough for the last two or three years, but did not think he had been losing flesh. He had not spat up blood or suffered from night sweats; in fact, up to the present illness he had enjoyed fairly good health.

On physical examination the left chest was found markedly distended. Percussion over that region gave a hyper-resonant or tympanitic note all over. On auscultation the breath sounds were markedly diminished or absent, vocal resonance was also diminished or absent, and the same may be said of the vocal fremitus. Percussion with two coins combined with auscultation gave the bell sound or bruit d'airain. On the right side posteriorly a small patch of dullness was found over the root of the lung on percussion, and auscultation revealed bronchial breathing, increased vocal resonance, and moist sounds. Over the rest of the right lung, both in front and behind, harsh breathing accompanied by moist sounds and an occasional bronchial r le was heard. The heart was displaced to the right, for the cardiac impulse could not be felt either in its usual situation or anywhere else, and on auscultation the heart sounds could not be heard at the left of the sternum, or, at any rate, only very faintly, but were well heard just at the right margin of it. All these symptoms, pulmonary and cardiac, pointed to the case as being one of pneumothorax and the sudden onset, together with the lung symptoms, seemed to indicate that serious lung mischief was the cause of the patient's state on admission. The diagnosis, then, was pneumothorax probably due to phthisis. The left chest was aspirated and a quantity of air allowed to escape. This confirmed the diagnosis, but gave no relief to the patient. He was placed on a stimulating plan of treatment, but died about fifteen hours after admission.

*Necropsy.*—The left lung was found to be collapsed and the pleural cavity distended with air. The lung on being cut into was seen to be riddled with what may be called abscesses for want of a better term, varying in size from a lentil to a nutmeg. These points of suppuration were probably tuberculous in origin and put the question of the cause of the pneumothorax beyond doubt. The right lung was in an exactly similar condition.

CASE 2.—Before describing this case a few remarks, from an account of "Fibro-adenoma of the Mamma," given by Dr. C. Schimmelbusch in the *Archiv f r Clinische Chirurgie* of this year, may not be uninteresting. He says: "They were first described by Cruveilhier as growths furnished with a connective tissue capsule, freely movable, never forming con-

nexions with the muscles or pectoral fascia, and only forming adhesions with the skin when some special irritation exists." Schimmelbusch, in addition, says: "The size of these tumours varies very much, some being as large as a child's or man's head. There is no relation, however, between the size and the age of the tumour. Some of the very small ones had existed for years and several of the largest had developed in less than a year. Consistently hard, almost cartilage-like. The large ones, however, are generally softer. Fibro-adenoma is more frequent in early life, but seen sometimes in patients over fifty and sixty years of age. Cruveilhier named them 'fibroma' at first, subsequently admitting their glandular character." "Pure fibroma" of the breast is extremely rare, hardly ever occurs. During the last three years all the mammary tumours in Bergmann's clinic have been carefully examined, and during that time not a single fibroma has been found. Schimmelbusch also describes their minute structure as follows:—"They are composed of epithelial elements whose type is that of the glands of the mamma, and of a firm or loose connective tissue lying in more or less broad tracts between the epithelial constituents. The connective tissue in firm tumours is fibrous with spindle cells; in the soft rapidly growing, of a loose myxomatous character. Only three or four acini may be found in one field under the microscope."

The following is an account of the case: E. L.—aged twenty-seven, labourer, was admitted into the North Riding Infirmary on June 14th, 1892, suffering from a swelling of the right breast in the region of the nipple. He stated that twelve months ago he received a kick directly on the nipple. The force of the blow knocked him over, otherwise he did not feel it very much. The breast was swollen and tender for a day or two, but this passed off, leaving no trace of injury. Six months ago he noticed that a small swelling had appeared just behind the nipple. This gradually increased in size, and he thinks it grew more rapidly a month prior to admission into hospital. The tumour was circular and a little larger than a crown-piece, the nipple being over the centre of it. It was firm, even to hardness, especially in its centre. It was freely movable under the skin, except at the nipple. It appeared to be somewhat lobulated and felt not unlike a mammary gland or a fatty tumour, only harder than either of these. It was not painful on pressure, except when directly applied over the nipple. It was thought to be either a fibroma (Dr. Munro had not then read Schimmelbusch's account) or a hypertrophy of the remains of the mammary gland due to the application of an irritant. However, as there was a history of rather rapid growth, and with this the possibility of its being malignant, it was decided to remove skin and tumour all away together. This was done, and the wound practically healed by first intention, allowing the patient to leave the hospital in a few days. The tumour was forwarded to Professor Greenfield of Edinburgh for examination. His report is as follows: "The tumour is composed of very dense fibrous tissues, with here and there a few scattered gland-like acini lined by columnar epithelium. It is, therefore, a fibro-adenoma, in which the stroma is very dense and approaches in nature a chronic inflammatory hyperplasia of the fibrous tissue of the gland. Now that it is removed it should give no further trouble."

### Reviews and Notices of Books.

*Lectures on Diseases of the Digestive Organs.* By C. A. EWALD. Translated from the latest German Edition by ROBERT SAUNDBY, M.D. Edin., F.R.C.P. Lond. Vol. I.: Lectures on Digestion. Vol. II.: Lectures on Diseases of the Stomach. London: The New Sydenham Society. 1891-92.

THE New Sydenham Society has been the means of bringing before the notice of the English reader many works of high merit which have appeared in foreign countries. The selection of Professor Ewald's classical treatise upon digestion has been no less happy than many others that have preceded it, whilst the assignment of the task of translating it to Dr. Saundby was fitting and could not have been better, for it was Dr. Saundby who twelve years ago published an English translation of the first edition of the Lectures on Digestion, and several years elapsed before the author produced his second volume. That there has been a considerable addi-

tion to our knowledge of the physiology of digestion since the first edition appeared is seen in the vast amount of new material now incorporated in the lectures. Professor Ewald has rendered a great service both to physiology and to practical medicine by his writings on this subject, for there are few conditions in which hitherto the gap between physiological knowledge and the practical application of such knowledge has been more evident than in that of digestion and its derangements. No doubt there is still much to be learnt, and it is true that in this country we do not practise to the same extent the new methods of examining the quality of the gastric juice in our patients as is done in Germany. Professor Ewald, who rightly regards physiology as the basis of pathology, is very sanguine of the future of these methods. He gives full directions for their pursuit, and were it not that their indications are at times uncertain they might gain more general adoption. The twelve lectures which compose the first volume cover the whole ground of the process of digestion, those of the second volume are confined to the diseases of the stomach. These latter lectures form an excellent conjunction of the scientific and the practical. The practitioner will find many suggestive remarks and valuable therapeutic hints in all the lectures, and even subjects so familiar as ulcer and cancer of the stomach are treated in a manner which lends them fresh interest. Of equal value are the descriptions of gastric dilatation and of the neuroses of the stomach, which latter, as Dr. Goodhart recently showed us, were often overlooked or disregarded. There was a distinct need for such a work as the present, and it will doubtless be taken as the type and pattern of the right method of treating the subject. We need hardly add that the translation is excellent.

*The Wife and Mother: a Medical Guide to the Care of her Health and the Management of her Children.* By ALBERT WESTLAND, M.A., M.D., C.M. London: Charles Griffin and Co., Limited. 1892.

THIS book, according to the preface, is addressed to women who are desirous of fulfilling properly their duties as wives and mothers. It is a difficult task to write a book with this aim which deals with medical subjects, as the knowledge conveyed by the writer is usually purely professional and the mode of treatment is apt to be too technical. On careful perusal of this volume of 282 pages we are inclined to think that the author has not altogether escaped this danger; but in saying this our fault-finding is at an end, because the book is well arranged, and though sometimes a little too verbose it is on the whole clearly written. The first part is concerned with early married life, and pregnancy and its attendant symptoms and effects are described. Motherhood is discussed in the second part. The development of the child and the common maladies of infancy are somewhat fully dealt with in the third division, the chapter on the nutrition of the child being very carefully written and the hints as to artificial feeding of infants reliable. The fourth part is taken up with the change of life and its discomfords. The book is well printed and contains a very full index.

*The Medical Pathology of Tuberculosis (Pulmonary Tuberculosis and Tubercular Phthisis).* By GEO. F. CROOKE, M.D. Edin. London: Baillière, Tindall, and Cox. 1891.

THIS little volume is composed of six lectures delivered to a post-graduate class at Queen's College, Birmingham. They cover ground which has been well trodden by pathologists in all countries for the past half century; but nevertheless they are fresh and original, and show that the author has arrived at his conclusions after much personal research. He rightly holds that we can only form correct notions on morbid processes by considering diseases in their clinical course as well as in the results brought to light by the morbid anatomist; and he attributes some of the divergences of opinion on the subject of tuberculosis to the too great stress

occasionally laid on the results of experimentation, rather than on those of bedside observation and pathological anatomy. His discussion of the histology of pulmonary tuberculosis is characterised by common sense, and his dictum that in phthisis there is a commingling of pneumonic lesions of various types and the specific growth of tubercle is accurate. The confusion of ideas on the subject has been brought about by the endeavour to see in all the phthisical process something specific, whereas, as Dr. Crooke says, the only absolute test of a tuberculous lesion is its conjunction with the bacillus. He holds, too, that in the majority of cases of phthisis the tuberculous infection primarily attacks the lungs, but that in a certain number there is antecedent local inflammation, whilst in others the lungs are secondarily infected, through blood or lymph streams, from a more or less distant focus. All who desire to have in compact form the essential points of the relationship of tubercle to phthisis will do well to peruse these highly instructive lectures.

*The Pathology of Mediastinal Tumours; with Special Reference to Diagnosis.* By JOHN LINDSAY STEVEN, M.D. London: H. K. Lewis. 1892.

THE institution of post-graduate instruction has been the means of enriching our literature with more than one monograph of value. The lecturers, recognising what is required of them, often select some special subject of interest, and having thoroughly analysed it, present the results of their study in a form capable of being weighed and appreciated. The volume before us arose in this way, being based upon a course of lectures delivered by the author in Glasgow two years ago. Although not so exhaustive in a bibliographical sense as the monograph by Dr. Hare of Philadelphia, it is in some respects a better study of the subject, and is especially valuable in giving full clinical details of cases illustrative of the various forms of mediastinal neoplasm. These growths are classified by the author under the headings of (1) sarcoma and lympho-sarcoma, (2) cancer, (3) fibroma, (4) tubercular and other specific new growths, and (5) miscellaneous varieties. He does well to emphasise the difference between Hodgkin's disease, in which the mediastinal glands may be extensively involved, and the primary more localised lympho-sarcomata which form a large proportion of mediastinal tumours, although the latter class may give origin to metastatic growths. There is a careful study of the relationships of mediastinal sarcomata to the various tissues and organs which may be implicated by them; and two cases of secondary mediastinal sarcoma are given, in one of which the primary growth was in the testicle, in the other in the femur. As regards carcinoma, we should concur with him in his statement of the rarity of the primary disease (endothelioma), and we hardly think that cancer of the oesophagus is strictly of this class. It is, however, doubtless included, since it arises in one of the structures contained within the posterior mediastinum, and the details of one of the recorded cases are of especial interest. In this case the cancer was situated at the usual site—viz., opposite the bifurcation of the trachea—and it caused death by ulcerating into the aorta. The rare condition of fibroma of the mediastinum—which is apparently different from callous mediastinitis, another rare condition associated with pericarditis and productive of pressure signs like those of tumour growths—is illustrated by one remarkable case where there were also subcutaneous nodules and a history of recurrent rheumatism. Not much space is devoted to other formations; indeed, more might with advantage have been said about bronchial gland tuberculosis, and the final chapter deals with the subjects of diagnosis and treatment. With regard to the latter none but palliative measures are available except in the rare case of syphilitic disease, for the mediastinum is beyond the reach of the knife and no internal treatment at present known can influence the growth of these tumours.

# THE LANCET.

LONDON: SATURDAY, AUGUST 13, 1892.

A FEW weeks ago we referred to an interesting report by Dr. J. KING WARRY, the acting medical officer of health of Hackney, on an outbreak of scarlet fever in Clapton. Dr. WARRY was able to associate this outbreak with the distribution of a particular milk-supply, but he could find no evidence as to the manner in which the milk became infected. There was no reason for believing that the milk was infected from a human source, but he noted that some of the cows whose milk came under suspicion had an abnormally high temperature and suffered from abrasions and cracks of their teats. We have now received a report by Dr. W. H. HAMER which has been presented to the London County Council and which gives an account of several outbreaks of scarlet fever in London and in districts adjoining London during the months of March and April of the present year. These outbreaks were also traced to the distribution of an infected milk-supply. In these cases the milk which came under suspicion, instead of being received from the country, was derived from a London cowshed in the possession of a contractor, who also received milk from some forty farms. The London shed milk was distributed locally and was also used to supplement other supplies when these were insufficient for the purposes of customers situated in different districts in the neighbourhood of London. Unfortunately, owing to the absence of sufficient record of the distribution of these numerous supplies, it was impossible for some time to discover which was at fault, and it was only after painstaking investigation that evidence was finally obtained that the London shed milk was to blame. In the meantime outbreaks of scarlet fever due to this cause occurred in Charlton, Plumstead, Bexley, Greenwich, Deptford, Chislehurst and Sidcup, all of which were carefully investigated by the medical officers of health of these districts and the results of the inquiries were freely placed at the disposal of Dr. HAMER, who has been able to show that the London shed milk from March 25th or 26th to some day in the first week of April was causing disease in these localities.

As in the case of Dr. WARRY at Clapton, so in that of Dr. HAMER careful inquiry failed to show that the persons employed in the milk business or their families had recently suffered from scarlet fever. Dr. HAMER, however, in considering the question of bovine contagion, comments on the fact that on March 25th a black-and-white cow was noticed to have a cough, to be "off her feed," and to be yielding milk which was "ropy." The ropy character persisted for seven or eight days. This cow and four other cows which were milked by a particular milkman presented on examination of their udders and teats certain scabs and excoriations. The fact that the more serious disturbance of the black-and-white cow's health, which was attributed to a cold, had led to interruptions in the continuous use of its milk caused Dr. HAMER to notice whether there were any coincidences between the behaviour of scarlet fever in the different

districts and the times of these interruptions. He observes that the six days on which the black-and-white cow suffered from a cold were the six days of maximum infective power of the milk supplied to the several infected localities, and that after April 1st, the day when the treatment of the cow was first commenced and after which date the milk of this particular cow was on several occasions excluded from the business, the infective property became less marked. On April 8th the milk of this cow and that of the other four cows which had eruptions in their teats and udders were excluded from the business and all evidence of further milk infection ceased, but on this day also the milk of all the other cows was "scalded" before being distributed, and it is therefore impossible to say whether this cessation was due to one or the other circumstance.

Dr. HAMER has contented himself with an account of his investigations without drawing any conclusions as to the manner in which the milk became infected, and in this he has no doubt acted wisely, although the history of the outbreak may seem to be suggestive of the view that infection resulted from some condition of the cow. Evidence of this nature would appear to be by degrees accumulating, and should lead eventually to a more detailed study of the minor ailments of the cow than these maladies have hitherto received. The subject is one which especially concerns the veterinary profession, and it may be hoped that the publication of these reports will have the effect of demonstrating the necessity for more knowledge than at present exists. Similar careful investigations of other outbreaks will no doubt throw further light on this question.

If not yet a science criminal anthropology is now a subject of scientific discussion, and as such has asserted its right to a place in the programme of the British Association. Year by year the problem with which it has to deal is so far approaching solution that its limits are more clearly defined and the conditions under which it can be solved more practically appreciated. Many workers for a generation and more have been in the field, and among these, as Dr. CLOUSTON reminds us, there were three compatriots who signally facilitated the inquiries of their successors. These were Dr. BRUCE THOMSON, of the Perth Penitentiary, Dr. DAVID NICOLSON, of the Broadmoor Asylum, and Dr. WILLIAM WILSON. By these physicians it was established beyond the reach of criticism that criminals inherit their qualities and transmit them, often aggravated seldom diminished, in their turn; that they constitute a distinct and, under easily recognisable features, a numerous class; and that the only effectual way of dealing with them is, primarily at least, to disperse them and, by preventing their cohabitation, to check the reproduction of their kind. Schooled in this teaching, the French followed it up by observation and induction which went far to strengthen it and to diffuse its acceptance. In connexion with the police system of Paris medico-psychological experts, like the late Dr. BERTRAND DU SAUL, were appointed to examine in the morning the persons arrested over-night, and very often to relegate to the asylum cases which would merely have been sent to prison. Incidentally we had occasion, when commenting on that

great physician's life-work, to adduce striking instances in which his timely intervention saved the victim of cerebral disease from condemnation to criminal society—cases in which the victim so rescued returned to thank him for restoration to moral health and for delivery from an atmosphere and from influences in which the temporary lapse from mental soundness would have been fostered, if not stereotyped, past recall. Later still, the profession in Italy—mainly in the sub-Alpine and Neapolitan schools—utilised its unique opportunities of observing and analysing crime and its causes so as to extend the teaching of the British and the practice of the French pioneers, and, in the well-known works of LOMBROSO and COLAJANNI, to make the beginnings at least of a science of criminal anthropology. Nor must the labours of the distinguished neurologist and alienist, Dr. BENEDIKT, of Vienna, be omitted in this connexion. It is to him we owe mainly the now widely recognised principle of "studying criminals in different types," and of thus gradually building up the materials of an induction of which the next step would be the establishment of criminal anthropology as a science.

Dr. CLOUSTON was very lucid in his exposition of the factors of which criminal anthropology must take cognisance. Three in number, these are—first, the heredity of the criminal; second, the criminal's brain, with its reactive and resistive qualities in each case; and third, the criminal's surroundings, with their effects, both immediate and permanent. The first of these takes account of the past history, chiefly the neuropathic history, of the criminal's family and the transmutation of its inherited diseases into other diseases in offspring. Malnutrition, privation, sense of insecurity, all the incidents of a lawless struggle for existence come within the inquirer's purview, "while atavism and reversion of many sorts" might furnish a clue to the problem in any individual case or family. The second factor, that of the essential qualities of the brain, its receptivity and reactive power, its resources in self-control, especially in withstanding pain, fear, temptation and such trials of the moral sense, comes next to be considered. This covers a wide field and presents the greatest difficulties to the investigator—a field in which, intelligibly enough, the Italian school has made the most valuable contributions, as the abolition of capital punishment in Italy, by preserving the lives of the most typical class of criminals, has furnished the best means of studying them *intus et in outo*. In the Medico-Psychological Museum recently founded by Professor PAOLO MANTEGAZZA at Florence we find a further aid to research in this department, especially in the grooves in which the energising brain is apt to run, sensually, morally and even intellectually. The third factor includes the mental and social atmosphere in which the subject of crimino-anthropological inquiry has been brought up and must comprise early companionship, moral and religious influences—all, in short, that contributes to motive in its less healthy issues. Those tracts of the brain cortex organised for mental processes are the field in which the future character of the individual—criminal or non-criminal—germinates and grows; they are, as Dr. CLOUSTON well puts it, "the fullest of hereditary qualities, the most powerful, yet the most notable, by far the most physiologically valuable part of man," and the question that confronts the student of criminality he formulates thus: "Have we among us' men and women whose mental

cortex is of such quality that in its ordinary environment the conduct of its possessors must necessarily be anti-social and lawless? and if so, what anatomical, physiological and psychological signs are there to distinguish this criminal cortex and its possessor?"

The Italian and some of the German school assert that such signs exist and are not difficult to recognise—that, in fact, the criminal was a criminal potentially long before he was one actually. With characteristic caution, British jurisprudence is slow to admit this; nay, virtually denying it, it takes no measures to meet it; while on the Continent, wherever the abolition of capital punishment has been agitated or placed on the Statute-book, it has been largely appealed to as a rationally ascertained fact. Between the cautious attitude of the British law and the confident procedure of the Italian there is surely a *via media*, and this, we think, Dr. CLOUSTON has well indicated. Criminals, it will be admitted, generally come far short of a high or ideal standard of brain, body and mind. That being accepted, the next step is to work in the field it prescribes, taking all that enthusiasts like LOMBROSO or MANTEGAZZA or BENEDIKT can offer of sound or even suggestive material, and utilising every opportunity afforded by our more intimate cognisance of the life, normal and abnormal, seething around us to accumulate the observations and the facts on which a sound induction must be based. Inhibitory paresis, for instance, may be admitted to be a pathological condition without expecting for it judicial or even forensic acknowledgment, while all that the medico-psychologist can hope to do is steadily to accumulate such evidence of it as science can accept, and gradually to conquer for it and for the class of truths which it typifies the concurrence of popular opinion and ultimately of the law itself. The President of the Anthropological Section, Professor MACALISTER, had a good word to say in this connexion for the draconian law, which, by extending capital punishment to petty larceny, stamped out the criminal class on the threshold. CARLYLE, in his "Latter-Day Pamphlets," has similar recommendations for what he calls "the devil's regiment of the line." But science will work on the more humane view that society is responsible for its degenerative types, and that it must leave no effort untried for their rehabilitation till, with the establishment of sounder and healthier conditions, it creates a social organism in which crime will become as preventable as disease.

THE discussion at Nottingham on cardiac tonics, if not materially advancing our knowledge of an important chapter in therapeutics, was valuable as serving to "mark time" and to suggest lines for future inquiry and research. Dr. CLIFFORD ALBUTT was no doubt right in affirming that our knowledge on this question is still rudimentary and obscure, but the general assent accorded to most of the positions taken up by Dr. BROADBENT in his thoughtful and philo-sophic address shows that a considerable measure of agreement has been reached upon many points. Thus, clinical observers are practically unanimous that of the large group of cardiac tonics digitalis is much the most potent and trustworthy member, that strophanthus is also a valuable agent, though on the whole much inferior to digitalis, and that the utility of convallaria, caffeine, casca and spartein,

though occasionally striking, cannot be highly rated. It is when we come to the more minute points regarding the precise mode of action of these remedies and the indications and contraindications for their use that the widest divergence of view is found to exist. To some of these still disputable points we may profitably direct attention.

Digitalis naturally claims priority of attention, not only as the most efficient of cardiac tonics, but also as the agent to which the ordinary practitioner almost invariably gives the first trial. It is now practically certain that digitalis is not a simple substance, but a composite of several active principles, of which the action upon the vascular system is by no means uniform. Professor KOBERT has described three such principles—viz., digitalin, digitalein and digitoxin—and affirms that, whereas the first of these contracts all the vessels, the latter two dilate the vessels of the kidneys. Dr. LAUDER BRUNTON confirms the view that in the foxglove we have antagonistic principles at work, and it is obvious that until these have been isolated and separated we are still using a clumsy and inexact, although most valuable, weapon. Another point around which much doubt still lingers is the comparative action of digitalis upon the cardiac muscle and the arterioles. Dr. BRUNTON and most British authorities believe that digitalis acts powerfully both on the heart and the arterioles; but many good observers, especially on the Continent, doubt its direct action on the arterioles. This is a point of great practical importance upon which greater precision of knowledge is highly desirable. Assuming the correctness of the former view, many pharmacologists have directed their efforts to the search for an agent that would stimulate the heart without contracting the arterioles, and it is claimed for strophanthus and oxy-sparteïn that to some extent they fulfil this indication. This claim must still be regarded as of doubtful validity.<sup>1</sup> Another important point is whether digitalis, which so manifestly increases the fluids of the urine, also increases the solids, and if not, whether any agent could be found having such action which might be advantageously combined with digitalis. Caffeine has been supposed to fulfil this indication, but apparently on very insufficient grounds. Casca and convallaria are, we imagine, relatively but little used, and we are not aware of any recent evidence tending to raise our estimate of their utility.

When we come to inquire into the indications for the use of the various cardiac tonics, and especially their applicability to the different valvular lesions, we engage in a difficult search. A considerable measure of unanimity has, however, been attained on several points. It is hardly doubtful that the brilliant successes of digitalis are chiefly found in cases of mitral regurgitation and in aortic disease with sequential mitral involvement. The utility of the drug is certainly much less evident in obstructive disease, whether mitral or aortic, and in the former case—i.e., in mitral obstruction—some observers deny its value altogether. The point around which controversy chiefly rages is the mode of action and therapeutic value of digitalis in aortic regurgitation. On this point we must declare our decided preference for clinical experience over mere theoretical considerations. The plausible argument that, inasmuch as digitalis prolongs the diastole, during which in the affection in question a reflux current of blood is flowing into the left ventricle, it must necessarily act injuriously is really of little weight when put side by

side with the hardly questionable fact that many patients with pure aortic regurgitation manifestly improve under digitalis. Further, this theoretical argument, apparently so conclusive, is really open to several objections. It is quite possible that digitalis might so strengthen the ventricular systole as to promote the efficiency of the cardiac contraction to an extent that would more than counterbalance the presumable loss during diastole. Apart from theory, there seems decisive clinical evidence that digitalis is often beneficial in aortic regurgitation, even when there is no discoverable co-existing mitral failure. Another broad clinical rule that seemed to find general acceptance was that in aortic regurgitation accompanied by mitral symptoms digitalis acts well, but that if the symptoms were distinctively aortic—such, for example, as thoracic oppression, vertigo &c.—its utility was much less manifest. It was suggested in the course of the discussion that sudden death in aortic regurgitation had become more frequent since the general introduction of digitalis and other cardiac tonics into practice. Any precise evidence on this question would be valuable, but the point is very difficult of determination.

It is to be hoped that the great attention now given to cardiac tonics will not withdraw the minds of practitioners from those other agents in the treatment of heart disease upon which Dr. BRUNTON wisely laid so much stress—viz., rest, graduated exercise and the elimination of waste products. The wise apportionment of rest, the cautious but not too timid resumption of regular exercise, the occasional administration of a mercurial purge and other eliminants—these are points of the first magnitude in the management of cardiac disease.

To denounce the Church, particularly the mediæval Church, for its antagonism to rational medicine is an easy task, so easy, indeed, that the denunciation has long been one of the *loci communes* of positivist rhetoric. True enough, the ecclesiastical mind, both before and after the Renaissance, studied nature and nature's laws from the schoolmen's travesty of ARISTOTLE. It eyed with more than suspicion the lay practitioner who dared to look disease in the face and who, having satisfied himself that it was neither more nor less than a departure from health conditions rationally observed, set himself to treat it accordingly. It is also true that the Church opposed to this appeal to natural law its invocation of the saints, and that it sought by the dearly purchased intervention of these mediators to cure the sick—a practice which put money into its purse and riveted its hold on the popular imagination. Equally true is it that it saw, or professed to see, in lunacy or epilepsy only demoniacal possession, and that it preyed upon the superstitious relatives of patients so visited by claiming the power to exorcise the demon and by exacting heavy fees for the operation. That it encouraged personal uncleanliness is also true—indeed, the encouragement is not yet extinct, for only a few years ago it canonised one LABBÉ of Boulogne for no other apparent reason than that ages ago he had "crucified the flesh" by leading the life of a hog in such places as the arches of the Coliseum in Rome. Not, indeed, till sounder views of Nature and of the mode of interpreting her aright arose with GALILEO, BACON, and DESCARTES did the Church abate her pretensions to supernatural cure and allow rational medicine, though with

a bad grace, to pursue its course unfettered. All this, we repeat, is a more than thrice-told tale—become so tiresome by repetition that a reaction in favour of the Church has for some time set in, and historians of medicine (like HAESER and PUSCHMANN) have been at pains to show wherein the healing art is indebted to the Church, and how all denunciations of her undue pretensions ought to be tempered by an equally strong exposition of the blessings she has conferred. We have been led to write in this strain by an article contributed to the *Albemarle Review* by the Rev. ALFRED MOMBRIE, D.D., wherein he inveighs against the mediæval Church for her attitude towards medicine, in apparent forgetfulness, if not ignorance, of what the ecclesiastical—aye, and even the medical—apologist can say or has said in her vindication. Against his unrelieved invective we might quote the brilliant chapter in PUSCHMANN'S "History of Medical Education," which puts in the strongest and most convincing light the revolution in the estimate of man and of human nature wrought by the Church. A patient in the "valetudinaria servilia" of heathen Rome was cared for and cured, not out of brotherly love, but out of his owner's reluctance to part with a negotiable chattel, which might yield him gain, either by service or by sale. Not so the Christian view. The growth of its essentially humanitarian spirit lies at the root of hospital creation and extension in the modern sense; and few chapters in the history of medicine are more instructive and at the same time more romantic than those in which a HAESER or a PUSCHMANN traces the rise and spread of these beneficent institutions to the brotherly love as enjoined by the Church. The "Storia della Medicina" of the great Tuscan physician and jurist, FRANCESCO PUCCONOTTI, devotes many pages to proving how much that was sound in ancient medicine owed its rescue and conservation to fathers of the Church who were also, like S. BASIL, founders of hospitals and indirectly therefore creators of the modern clinique. Not till patients were massed and grouped on the scale represented by the mighty infirmary at Cæsarea was the observation of disease adequate for the purposes of pathological and therapeutic induction; not, in a word, till the multiplication of hospitals which followed that typical anticipation of the modern institution was the foundation of clinical research and practice properly laid. In taxing the Church with her baneful influence on medicine, the Rev. Dr. MOMBRIE tells us but half the truth, leaving it to the medical historian to make good his omission and to enable the impartial reader to "look on *this* picture and on *that*." Curious are the developments of modern polemical literature when an able and accomplished ecclesiastic like Dr. MOMBRIE indulges in an unrelieved indictment against the Church's demeanour towards medicine, and when the defence of the Church proceeds from medically trained apologists whose historic fairness forbids their ignoring the blessings it has conferred on their art.

In consequence of the retirement of Sir Joseph Lister from the Professorship of Clinical Surgery at King's College Hospital it has been necessary to make certain alterations in the appointments. The Chair of Systematic Surgery, which for the last year has been held conjointly by Professor William Rose and Professor Watson Cheyne, is now occupied solely by Professor Cheyne, while Professor Rose has been appointed to the Chair of Clinical Surgery.

## Annotations.

"Ne quid nimis."

### CHOLERA: ITS PROGRESS AND PROSPECTS.

SINCE our last account of the diffusion of cholera in Russia a further spread of the disease has taken place, and although the prevalence is still, in the main, confined to the eastern half of Russia, yet a slow extension westwards still goes on. At the beginning of the month Saratoff, Jaletz in the province of Orel, Riasan and Moscow were amongst the places either newly infected or subject to a large increase of attacks; there was also a considerable increase of the disease in the Don territory and in the government of Rostoff. At least one suspicious case had also occurred at Battonya in Eastern Hungary and a few in the eastern quarter of Pesth, but there have been no similar recurrences in Austria-Hungary. The disease next appeared at Kursk in Central Russia, extended at Moscow, at Nijni-Novgorod, at places along the Moscow-Kasan railway, and reappeared at Jamboff and at Jaroslav; and from certain districts definite statistics came in. Thus on Aug. 2nd there had been in Rostoff and Nakhitchevan and the neighbouring districts no less than 1150 fresh attacks and 559 deaths, and for the two days Aug. 1st and 2nd the Russian official records gave a total of 4107 fresh cases and 2073 deaths. Gradually the cases in Moscow were increasing and a severe outbreak took place in the province of Rostroma and at Ekaterinoslav. On the 5th inst. the total cases officially recorded for Russia had reached 6076 and the deaths numbered 2901. On the 6th inst. the cases were 4123 in number and the deaths 2493, the disease being most severe in the Don territory, at Saratov and Samara. One fatal case had occurred in St. Petersburg; the patient is, however, alleged to have been brought into the city ill and no known extension has occurred. Thus far the most westerly provinces affected are Yaroslav, Moscow, Orel, Kursk, Poltava and Ekaterinoslav. The progress westwards therefore is not rapid, and we are still of opinion that, so far as Russian cholera is concerned, there is a substantial chance that, for this country, no immediate emergency may arise this summer and that the greatest fear lies in a recrudescence next year of the widely scattered cholera contagium over the eastern and central portions of the Russian empire. In Asia the disease has made some further advance in the Persian empire. Lahijan, near the southern coast of the Caspian, has been attacked, and a daily mortality of some twenty-five is prevailing in Teheran. Around Paris the disease which has now for some time prevailed, and to which different authorities give different names, is still maintained, although a substantial diminution in its extent has set in. So far as the capital itself is concerned Dr. Proust declares the danger to have passed, and even in the suburbs there are strong indications of a subsidence. In Paris itself Dr. Proust asserts that no case of true cholera has arisen, and he also declares that during the four months' prevalence in the suburbs the disease has lacked the characteristics of imported cholera. We are not quite clear as to the precise meaning of this latter statement, especially in view of the fact that the suburban cholera has been held by some to be a recrudescence of the imported cholera of 1884. And it is very significant that M. Netter, Bacteriologist to the Laboratoire d'Hygiène de la Faculté de Paris, should at the same moment issue a report in which he speaks of cases of "le choléra vrai à bacille virgule" which have been contracted in the suburbs. Dr. Proust's statement, that the disease is everywhere due to Seine water, seems to imply that the cholera bacillus is not regarded as a necessary means of infection, for M. Netter also announces that there are no comma bacilli in the water-supply distributed to Paris, even in the quarters where Seine

water is delivered. The several reports do not, in point of fact, clear up any of the difficulties which have arisen as to the true meaning and the causation of the cholera in the suburbs of the French capital. Germany, it is announced, has stopped the immigration of Russian Jews into her territory; but nothing is said as to the transport across Germany of these people into this country. This latter subject has attracted the attention of the Government in view of a risk of cholera importation, and we understand that Dr. Theodore Thomson of the medical department of the Local Government Board has been making inquiries as to this immigration in the Port of London, in the London Docks, and at some of our eastern ports.

#### THE HYGIENE OF THE TEETH.

THE value of preventive measures against the attacks of disease cannot be too strongly insisted upon, and one class of case where these measures are to a great extent within the control of the individual is in regard to the teeth. All caries of the teeth begins from the outside, no such thing as internal caries having ever been demonstrated; hence if the surfaces could be kept absolutely clean no decay could take place, however poor the texture of the teeth. This is of course impossible, but much towards such a desirable end can be attained by attention to hygienic rules. Parents often ask their dentists and medical attendants with reference to their babies: "When ought teeth to be cleaned?" The answer assuredly is: "As soon as there are teeth." A very small toothbrush charged with some precipitated chalk flavoured with an aromatic drug to make it pleasant is perhaps the best means,—not a towel, which only removes the secretion from the labial and lingual surfaces and not from between the teeth, where decay is most rife. Yet how few children's teeth are so treated, and how rarely the habit of doing it for themselves when they are old enough is inculcated. But if it be acquired the very desirable result is likely to follow of an immunity from dental trouble—at all events to any large extent. Later on something more can be done, by passing a piece of waxed dental floss silk, which can be obtained of most chemists, between the teeth every day, and the value of this can be easily demonstrated after thoroughly using the toothbrush by passing the silk between the teeth, when a certain amount of accumulated matter will be brought away. "Do toothpicks do harm or good?" is another question often asked. They may do harm if abused, undoubtedly, by causing irritation of the gum between two teeth and its subsequent absorption; and, if made of wood, splinters are liable to be left behind, which have in many recorded instances caused even the loss of a tooth; but used judiciously they are of great value in routing the attacking forces in caries—namely, accumulations of food and mucous secretions. It has been urged against them that they might dislodge a stopping. But if a stopping is so insecure it must be faulty, and the sooner it is replaced the better, for decay, due to the impossibility of keeping the surface clean, must be going on underneath it.

#### "MEDICAL MEN AND STIMULANTS."

"A CLERK in Holy Orders" asks to be allowed "to protest against a practice of the faculty which he says is by no means uncommon," alluding to the indiscriminate prescription of alcoholic stimulants in disease. Unfortunately our space is too limited to give insertion to all the communications which reach us from medical men, and we should be hopelessly embarrassed if we once opened our columns to the discussion of lay views of medical science and art. Still we entirely appreciate the good motive of our correspondent and the tone of respect and moderation with which he speaks. We do not differ from him in his disapproval of the "indiscriminate" use of alcohol, or in thinking the results of such

use highly pernicious. We do not doubt that alcohol is sometimes prescribed indiscriminately. Even medical men are fallible and they have to work upon material which is often very faulty and which brings even a good remedy into discredit. What we maintain is that all practitioners and all medical writers of authority treat this subject gravely. They give no countenance to the "indiscriminate" use of alcohol. Mr. A. Pearce Gould protested strongly at Nottingham against the excessive use of alcohol in his earlier days. He testified that he had practised such surgery as came to him almost entirely without the use of alcohol, and that he could not see where the value of alcohol came in except in the most unusual cases. Professor Victor Horsley followed in the same strain. If there is one set of diseases in which alcohol is specially valuable it is in the continued fevers. Let anyone glance at the classical work of Dr. Murchison and his views on the therapeutic use of alcohol in fevers or the various writings of Dr. Gairdner on the same subject, and he will see how judiciously they write, and how they both testify that many cases of typhus fever do perfectly well without alcohol, and that even bad cases are injured by more than very moderate quantities. Dr. Murchison said "that patients under twenty do best without alcohol," and "that it is very rarely necessary to give more than eight ounces of brandy (that is of course in the twenty-four hours)." In Dr. Gairdner's practice, with a very low mortality, nine-tenths of the patients had no stimulant at all, and the whole quantity consumed gave as an average to each patient in twenty days and a half two ounces and a quarter of wine and two ounces and a half of whisky. We have no right to believe that there are any considerable number of medical men treating these diseases on other principles. The same is true of other diseases. A delusion that alcohol antagonised tubercle has been exploded by Dr. Dickinson and others. Sir William Gull and many others have shown that even moderate quantities of alcohol have to be taken with care by many people if harm is not to result. To suppose that any number of practitioners prescribe alcohol recklessly without remembering its power for evil over gland and nerve tissues, and the weakness of human nature with regard to it, is to be guilty of uncharitableness to a great profession. We never lose an opportunity of pointing out the responsibility of prescribing alcohol either in hospital or private practice. We must remind our lay critics that the medical man is often blamed when the patient really is at fault.

#### THE INTERNATIONAL MEDICAL CONGRESS OF 1893.

AN Italian correspondent writes: "Dr. Baccelli, whose presence with Professor Mariano Semola at the Association meeting at Nottingham gave such satisfaction to his compatriots, has returned to Rome and resumed with redoubled energy the preparations for the international *réunion* of the profession to be held in the last week of September, 1893. In addition to the work of mapping out the agenda of the various sections and appointing their *personnel*, he is engaged in pushing forward to completion the great hospital of the Policlinico Umberto I., which has been slowly rising from its foundations outside the Porta Pia, at the south-eastern quarter of Rome. The building, over and above its many novel and striking features, some of them unique in hospital construction and all of them calculated to facilitate its working as a clinique of the first order for research, for treatment and for tuition, will also present not a few artistic details peculiarly interesting to the profession at large and to its British representatives in particular. The façades of the two sections devoted to clinical medicine and clinical surgery will each have a memorial, sculptured in bas-relief, of the most momentous innovations in these departments—one of them devoted to Morgagni, the father of modern pathology,

the other dedicated to Lister, the pioneer of antiseptic practice. These designs, which for many months, I believe, have been in the hands of competing sculptors and are shortly to assume definite shape in the two weeks finally approved by the adjudicating committee, will not be the only ornament of an artistic kind which will lend attraction to the Policlinico Umberto I. Its administrative offices, constituting the Palazzo dell' Amministrazione del Policlinico, will also have the façade adorned by a group in bas-relief representing some characteristic event or incident in the history of therapeutics. A programme, drawn up by the Superior Council of Public Works, to regulate the competition for this art product has just been approved, the competitors to be drawn from the sculptors who either reside or have their studios or professional residences in Rome. Their work must be sent in and the successful group decided on in time to occupy its place on the façade in the autumn of 1893, just before, that is to say, the assembling of the International Congress. With regard to the other hospitals in which Rome abounds, and the unsatisfactory state of which has frequently been described in THE LANCET, it is reassuring to know that the Government is fully alive to the necessity of rehabilitating them, so as to make them at least 'presentable' when, a year hence, the heads of the chief European clinics commence to arrive. The Commendatore Silvestrelli, who acted as Royal Commissioner to inspect, report upon and improve these hospitals, has resigned, mainly, it is said, on account of the insufficient pecuniary subvention placed at his disposal for the carrying out of his suggestions. A substitute for him has been found in the Senator Colucci, sometime Prefect of Palermo, and Dr. Baccelli and his colleagues have drawn from the Prime Minister, Signor Giolitti, assurances tending to allay their doubts as to the provision afforded under the new arrangement for keeping the actual *personnel* of the hospitals up to its normal strength, so as in no wise to impair their efficiency in the interests of the public or the profession. Amid the many demands on the State purse of Italy none are more justified than these of her medical and surgical services, no country in Europe being in greater need of such adjuncts to national wellbeing or possessing greater ability to turn them to profitable account for the healing art as a whole."

#### THE ORIGIN AND DIFFUSION OF CHOLERA.

SURGEON-GENERAL CORNISH, C.I.E., has contributed a paper to the current number of the *New Magazine* on the Origin and Diffusion of Cholera. Apart from the obvious interest which the subject possesses at the present time, when European countries are threatened with the prospect of a new cholera invasion on a large scale, the paper merits attention from the fact that its author has acquired a practical knowledge and experience of the disease in the East from the official position he held in India. Allusion is made, first of all, to the great value of the late Mr. J. Netton Radcliffe's labours during his lifetime in having conscientiously chronicled and recorded the facts about the progress and geographical distribution of epidemic cholera from year to year, whenever that disease overflowed the limits of its natural home in the great river deltas of Lower Bengal and India. Reliable information from health officials regarding the progress of epidemic cholera is essential to a correct judgment regarding the liability of any particular area to invasion. So far as can be gathered, Surgeon-General Cornish says, the epidemic which now threatens the whole of Europe appeared in March or April of the present year in the North-Western Provinces of India, attacked with great violence the pilgrims at the great Hurdwar fair near the source of the Ganges, spread through Cashmere and Afghanistan, reached Persia in

May or June, crossed the Caspian Sea and spread amongst the population of Asiatic Russia, from whence it is making rapid progress in European Russia. The epidemic since April has travelled in a north-westerly direction and has covered or overflowed many thousands of square miles of territory. The history of the progress of the great epidemic of cholera of 1829-33 should be closely studied by those who wish to understand the significance of the present epidemic. Cholera history is very apt to repeat itself, and the circumstances which happened in 1831 are therefore very likely to happen again in 1892 and succeeding years. The route taken by the present epidemic is almost identical with that which invaded Europe in 1831. It is quite a mistake to suppose that since India is the natural home of cholera the disease is everywhere present there and ready to take an epidemic form. An epidemic of cholera follows the same laws in India as in any other country. It is endemic only in certain and limited parts, from which an epidemic advances occasionally, with intervening intervals of uncertain duration. Its progress is influenced by season and atmospheric conditions and after lasting a period of about three years the epidemic dies out. Surgeon-General Cornish questions whether the cholera in the suburbs of Paris, with its peculiar and circumscribed topography and weak infective power, can be attributable to the same cause as that which has invaded and is now advancing in Russia. He alludes to that country's half-civilised acquisitions in Asian soil as a source of difficulty and danger in this direction, and considers that, as far as the safety and happiness of her people are concerned, the wealth now spent on the maintenance of a huge army and on ambitious schemes for extension of territory would have been more efficiently laid out in the improvement of the sanitary and social condition of the populations under her rule. As regards land quarantine and sanitary cordons, which European nations are so ready to enforce against their neighbours, these have never been successful in keeping out cholera. In India, with ample military aid at hand, they have been tried again and again unsuccessfully. The only provisions on which any reliance can be placed are sanitation, a good water-supply, efficient drainage, surface soil cleanliness, wholesome food and habitations. The invading cholera, if it does not reach this country in the present autumn, is, in Surgeon-General Cornish's opinion, likely to do so in 1893. Happily the early accession of cold weather has apparently had the effect, to which he alludes, of repressing the progress of the disease for the present. The moral of this matter lies on the surface. What we have to do in the meantime is to seek out and repair the weak places in our sanitary harness.

#### THE DANGERS OF SCIENTIFIC RESEARCH.

THE death of Dr. H. J. Tylden from typhoid fever, contracted during the progress of an investigation upon this disease that he was making at the Embankment Laboratories, leaves hardly room for doubt that he contracted it directly from the bacillary cultures which he was studying. We understand, moreover, that coincidentally with his illness one or two inmates of the building were also attacked, and that one of these cases proved fatal at an early stage of the disease. No doubt the matter will be thoroughly inquired into, and it is of course quite possible that neither Dr. Tylden nor the others contracted the fever as supposed. On the assumption that it was so contracted it illustrates the risks which those who devote themselves to scientific researches run, and the need for the exercise of every possible precaution by those who deal with infective viruses. Obermeier, the discoverer of the spirillum of relapsing fever, fell a victim to the disease contracted in his investigations; and although we believe that the case of the late Dr. Tylden is the first on

record where typhoid fever has been contracted from cultures of the bacillus simply (always supposing that he did so contract it), yet there are many instances of physicians becoming attacked by it when engaged in examining the dejecta of patients. Indeed, the martyr-roll of medical science is of greater length than we are wont to imagine, and it is, alas, generally those who are on the threshold of their careers who are cut off in the midst of their beneficent labours.

### BALDNESS AND ITS TREATMENT.

THERE are two classes of patients who resort either to the profession or to quacks—generally to the latter—for aid in the production or reproduction of hair in those parts of the scalp or face where it ought to grow, but owing to age or disease fails to do so. There is, first, the youth, who from vanity or a desire to improve his chances of employment, wishes to do before his time those hirsute appendages which are universally regarded as the outward sign of manhood: To him, in spite of the confident assertions of nostrum advertisers, we can offer little beyond the poor consolation of which he is well aware, that time is not only the sure, but almost the only remedy. No doubt those means which promote an increased circulation in the skin of the face will also promote the nutrition of the hair, and therefore, but only within narrow limits, increased growth in the more vascularised region. This doubtless is to a large extent the *modus operandi* of shaving, which, it is well known, increases the vigour of the hair in the region operated upon. The good effect of the slight irritation of the razor on the callow chin must not, however, be used as an argument for the application of stronger irritants, and the young man who, in his eagerness to hasten a natural process, painted strong acetic acid on his cheeks in the then approved mutton-chop shape, not only excited inflammatory redness and brought ridicule on himself, by publishing his youthful yearnings to all beholders, but also, by the inflammatory exudation produced, injured the nutrition of the follicles and hindered rather than helped forward the growth he so much desired. On the whole, patience, *plus* the adoption of all means which promote general invigoration of the system, and the avoidance of excesses of all kinds is the best advice that can be given to the beardless boy. The second class, apart from those who have a definite disease like alopecia areata, comprises those who are losing their hair prematurely, or even as a result of advancing age, and it is among these that the vendors of hair restorers find a ready market for their wares. It would take up too much space to discuss all the causes of baldness, which may be either of local or general origin, or of the two combined; but it is too much the custom, instead of investigating carefully into the general health and circumstances of the patient, and the exact condition of the skin of the scalp, to prescribe a hair lotion, in which may generally be found as the principal ingredient cantharides in some form or other. This, by attracting an increased blood supply to the part, is often useful, no doubt, where the baldness is due to mere sluggishness of the cutaneous circulation, but it fails altogether to reach the cause of that very large class who lose their hair from seborrhœa capitis. This is benefited by microbicide remedies—sulphur, mercurial applications of almost all kinds, and many other anti-septic drugs, both new and old. We do not know what particular microbe, among the legion which may be found in the greasy and dry scales in seborrhœa, produces the proliferation of epithelium, which, according to Unna, is directly due to an inflammatory process; but the effect on the follicle is such that it leads to atrophy of the hair, and if the disease is not arrested atrophy of the whole follicle and consequent permanent alopecia. Where the damage to nutrition is not so great the hair is lustreless and more or less marked canities ensues, and then the hair restorers, which colour the

hair from without and not from within, are eagerly resorted to. Sulphur and acetate of lead form frequent ingredients of these applications, while perchloride of mercury is too frequently the leading ingredient of a large number of vaunted remedies. No doubt it is of high value as a microbicide when employed in suitable cases, but used indiscriminately for months or even years injurious effects may be, and sometimes are, produced. Pilocarpine, hypodermically injected or given internally as tincture of jaborandi is certainly of value as a direct promoter of the growth of hair, but it is too powerful a remedy for indiscriminate use, and the copious perspirations and sometimes the cardiac depression it induces should keep its employment within narrow limits. Less direct means may be found in tonics of iron, strychnine, quinine &c.; but more powerful are cod-liver oil and change of air, generally to a bracing climate. It will be seen from the foregoing remarks that baldness is a symptom of such diverse conditions that there is no routine treatment for it, but the cause must be carefully sought out and intelligently treated, while the local treatment must be diligently and perseveringly carried out, as when due to its most common cause, seborrhœa, relapses are the rule, and constant watchfulness against recurrence is accordingly required.

### SANITARY PROCEDURE IN THE MEDITERRANEAN.

THE International Conference at Venice has not been tardy in showing its salutary results in Mediterranean waters. The jealous system of quarantine that paralysed commerce and added a fresh discomfort to travel is well nigh at an end. To effect this reform much local prejudice had to be overcome—prejudice for which we in Great Britain find it difficult to make due allowance. When an epidemic like that of cholera descended on the Mediterranean seaboard it found the harbour towns in so insatiable a state that it soon gained a foothold, and, thence reinforced, as from a base of operations, proceeded to advance inland. No such hygienic surveillance as prevails at British ports existed at those of Italy or France, and the ravages of the epidemic, instead of being ascribed to the auxiliary it found on landing, were set down to its native virulence, against which the only trusted safeguard was quarantine. The experience of a century has demonstrated that quarantine is no safeguard at all, and its supposed advantages are dearly purchased by the check it imposes on trader and traveller alike. A stricter sanitary system enforced at Mediterranean harbour towns will gradually inspire the confidence felt on British shores at the rumoured advance of an epidemic, and meanwhile the visitation of the sanitary officers with their disinfecting operations is about all the trading or travelling public in those waters have to dread. In bringing about this innovation the Italian Government have had to take into account impediments of which we in Great Britain can scarcely form a notion, chief among them being the ignorance and the consequent prejudices of a backward civilisation. A judicious middle course has been pursued, and while the procedure taken has, in point of thoroughness, been less than British it has, in point of courage, been considerably more than Italian. An illustrative case has just been reported to us from Neapolitan waters. The Prefect of Naples had been apprised that the British steamship *Albany*, on board which some cases of cholera had been announced, had been interdicted from landing at Malta, and that it was making for the port of Torre Annunziata with a cargo of grain. Conformably to the instructions of the Italian Home Office he telegraphed to every seaport in the province of Naples, Torre Annunziata included, that immediately the *Albany* hove in sight her captain was to be told either to pursue his voyage to England or to pass to the sanitary station on the island of Asinara. In virtue of this message the captain of the *Albany* cast anchor two miles from the Nea-

politian seaboard and signalled that he was in want of coal, of provisions, and of medicines. Before the understanding arrived at by the Venice Conference his intimation would have been ignored, and he would have had to await the passing of a friendly ship for the requisites he wanted. But thanks to that understanding the Prefect of Naples had no difficulty in satisfying his needs. The coal, provisions and medicines demanded were put on board a barque and conveyed from this to the *Albany* without any actual contact between the crews of either craft. Its service once rendered, the barque was thereupon burnt, and the *Albany* put off for the station at Asinara to undergo the visitation and the disinfecting processes which remain in force. Prejudice still counts representatives enough in Italy to censure the prefect for this humane and neighbourly act. Should cholera appear in Naples—a nidus in which it has hitherto found the welcome that a low standard of public hygiene invariably holds out—he will be blamed for his “recklessness” or “culpable indiscretion.” On the other hand, he will have the support of a more enlightened public opinion, embodied in the official understanding come to between Italy and Great Britain at Venice. That this latter consideration has now its due weight may be gathered from the leading Italian journals which have commented on the incident. The prefect, according to the *Nazione*, acted in observance of a policy “which meets all the requirements of the public health and, at the same time, all the exigencies of a country reputed to be enlightened and civilised. That the incautious should, on the one hand, criticise or declaim, asserting that Naples would have run no risk of cholera had the *Albany* been allowed to touch at Torre Annunziata; that, on the other, the timid should grumble or cry aloud that such weak-kneed tolerance as the prefect’s must favour the spread of cholera in the Mediterranean—all that,” adds the *Nazione*, “may be disregarded. Such mingled criticism and protest may fill the air, but will find no echo and soon die away. Acting in such a spirit and on such lines the Government will commend themselves to all just and sound-minded men at home or abroad, and with that commendation it may well rest content.”

#### REMOVAL OF BOTH OVARIES IN THE THIRD MONTH OF GESTATION; DELIVERY AT TERM.

AN interesting communication by M. Polaillon to the Académie de Médecine has reference to a woman who, in spite of a double ovariectomy performed in the third month of pregnancy, was nevertheless safely delivered at term. The history of the case is briefly as follows. First symptoms of the existence of an ovarian cyst appeared at the age of twenty-three, the patient being nulliparous. At the age of twenty-nine, menstruation having ceased for several months and symptoms suggestive of early pregnancy having appeared, severe pains in the abdomen suddenly developed. Examination revealed the presence of an enormous ovarian cyst, probably suppurating, the state of the patient being so serious that, despite the suspicion of pregnancy, it was decided to perform ovariectomy at once. At the operation, M. Polaillon came upon a large cyst of the left ovary, adherent to the intestine and to the Fallopian tube of the same side. The adhesions were ruptured, the proceeding giving rise to profuse hæmorrhage. The left ovary having been removed it was found that the right tube was the seat of hæmorrhage and that the right ovary, which had attained the size of an apple, was likewise affected with cystic degeneration. The right organ was in its turn removed. Recovery proceeded satisfactorily and the woman was in due time delivered, the labour presenting no unusual features and the placenta being normal. The cicatricial line was not injuriously distended during the evolution of pregnancy. The lesson deduced from this case by M. Polaillon is that pregnancy may continue after

the removal of the upper portions of the broad ligaments and despite the interference with the uterine and placental circulations entailed by the suppression of the superior uterine bloodvessels. He attributes the excessive hæmorrhage which occurred during the operation to the extra vascularity of the parts due to the gravid condition of the uterus.

#### FURTHER SAFEGUARDS AGAINST FLY BITES.

As we have repeatedly observed, the bite of an insect may entail much graver consequences than mere temporary annoyance. The irritable swelling which commonly marks the affected part is itself suggestive of blood poisoning, and this unfortunately is not in every case a purely local condition. It is this fact especially which gives to various insecticide skin lotions now in use a value which more than counterbalances the natural objection to their employment on the score of cleanliness. It is needful, however, to remember that all such applications are amenable to certain rules of composition. They must be themselves non-irritant, while at the same time antiseptic, and devoid of any sweetness of flavour which might attract the pest they are intended to combat. We should say that a mixture of one in four of carbolic acid recently recommended as a wash for clothing worn next the skin is too irritating for the integument of many persons if regularly used. An “insecticide scent” of lavender, eucalyptus &c., advised by the same authority as a face wash, conforms more nearly to the requirements above mentioned. We cannot, however, enter into the details of suitable preparations. The rural pedestrian should have no difficulty in acquiring these from any intelligent practitioner. Most persons could not do better than avail themselves of the protection afforded by a circular veil dipped in some antiseptic solution.

#### ANÆMIA AND MOUNTAIN AIR.

THAT *mal de montagne* is as distinct an ailment as *mal de mer* may be realised by all who make mountain ascents with great rapidity. *Puna* is its name on the Cordilleras and the high tablelands of Mexico, where, moreover, it has been known to cause death in subjects unseasoned to it by habit. It is due to the lower pressure of the atmosphere incident to lofty altitudes, or rather to the reduced oxygen pressure, whereby the gas is no longer capable of being dissolved in sufficient quantity in the blood of individuals accustomed to live in the plain. In such individuals, however, acclimatisation gives immunity from the *mal de montagne*, the circulation gradually increasing the number of the blood globules which, in greater mass, dissolve ever greater quantities of oxygen, and more than make up for the reduced pressure of the gas. It is to M. Paul Bert that we owe the experimental proof of this. Examining the blood of the llama or Peruvian sheep, he found that for every 100 cc. it absorbed, on an average, 20 cc. of oxygen, while in the herbivora of the plain the respiratory capacity of the blood did not exceed 15 per cent. Viault, with identical results, repeated the experiment on the spot. Müntz had the same experience on the Pic du Midi, where he left rabbits of the plain to live freely, and after a year found their blood much richer in hæmoglobin than that of the rabbits kept for comparison on the lowlands. To the experiments above mentioned, however, it may be objected that the increase in the hæmoglobin might be due to cold, to the open-air life, in short to the special conditions of the atmosphere which stimulate appetite and assimilation in animals. In answer to such objections Regnard, in his laboratory, subjected a rabbit, enclosed under a bell-glass, to a continuous atmospheric depression, two bell-glasses being so placed together as to admit of the rabbit passing from one to the other when it became necessary to effect certain cleaning and disinfecting operations. After

a month of this incarceration, where the atmospheric depression was such as to correspond with that of the Great St. Bernard or of Santa-Fé de Bogota (height about 3000 metres), the rabbit emerged, not very lively indeed, but to some small degree fatter. On the blood being examined, it was found that it absorbed 21 cc. per cent. of oxygen—that is to say, as much as that absorbed by the blood of the Peruvian sheep; while the blood of rabbits kept under normal conditions in the plain absorbs only 17 cc. It is therefore the atmospheric depression which increases the respiratory capacity of the blood in animals. Regnard's confirmation of his predecessors' results serves to explain the efficacy of certain climatic resorts in Switzerland, particularly in anæmic and chlorotic patients and in sufferers from neurasthenia. It is the atmospheric depression which, in conjunction with good hygienic conditions, acts on those invalids and promotes in their blood the formation of new sanguineous globules fit for the assimilation of oxygen. The more abundant nutrition and the augmentation of the appetite observable in a sojourn in the mountains are not the cause, but a consequence, of the improvement which such sojourn brings. Indeed, even admitting that the hæmatogenous action of elevated sites may owe something to other causes, as Viault contends, it is difficult to resist the induction of Regnard that climatic establishments are in general to be preferred to mineral water resorts—certainly to those whose reputation is chiefly built on fashion, on entertainments, or on the *ensemble* of adventitious attractions, from which health pure and simple has little or nothing to gain.

#### VENTRO-FIXATION OF THE UTERUS.

DR. SPAETH of Hamburg has now published reports of twenty-five cases in which he has performed the operation known as "ventro-fixation of the uterus." None of the cases proved fatal. In seventeen permanent anteflexion was obtained; in fourteen there was, besides the retroflexion, a diseased condition of the uterine appendages necessitating their removal. Of the cases that were not so complicated all except one were successful. Dr. Spaeth rarely fastens the stump of the broad ligament into the abdominal wound, usually stitching the fundus uteri directly to the parietal peritoneum. In the later cases he adopted Schede's method—that is to say, silver sutures were drawn through the whole thickness of the abdominal walls at intervals of about an inch and a half, but they were not at first tied. In the intervals finer silver sutures were inserted through the sheaths of the recti, the peritoneum and the fundus uteri, and tightened, twisted and cut short, the whole of course being beneath the skin; the thicker sutures were then tightened and twisted and the lips of the wound brought together with superficial catgut sutures. The subcutaneous silver sutures remained, but never gave any trouble. Dr. Schede and Dr. Spaeth are both of opinion that this method is the best for preventing any hernia, and that when it has been employed abdominal binders are unnecessary. Dr. Spaeth does not perform or recommend ventro-fixation in cases of retroflexion unless there is either disease of the appendages or chronic peritonitis.

#### POLLUTED WATERS IN CHESHIRE.

THE county analyst for Cheshire, Mr. J. Carter Bell, reports very strongly on some of the water-supplies which are in use in the county of Cheshire. He says that of twenty-nine samples which he has analysed, only ten could be regarded as good from the chemical point of view, whilst twelve were bad and seven exceeded in impurity the effluents from the Salford sewage. Having next referred to the causation of disease in connexion with the use of such waters, he deplors the fact that some elementary technical education is not given to cottagers as to the best way of fitting their water

for consumption, in so far as filtration will do this. And he explains that a filter efficient for this purpose can be made by means of a flower-pot, partly filled with sand and partly with magnetic oxide of iron or polarite, which may be purchased for about 1*l.* per pound. Where the water is very bad he advises boiling and then filtration; in other cases he advocates mere filtration; and he records that, as the result of his experiments with such means of filtration, purification was effected which amounted to something like 90 per cent. For such purposes as Mr. Carter Bell indicates we concur with him that substantial improvement would be effected, and we are practically content with the scheme which advocates boiling and then filtration, provided it be distinctly understood that the measure is adopted as a temporary one. The removal of 90 per cent. of matters which are undesirable unfortunately leaves a noticeable percentage behind, and unless we could feel assured that the 10 per cent. in question contains nothing like the specific material of disease, the practice cannot possibly be recommended as in any way taking the place of the provision of a water-supply which shall not run the risk of containing dangerous material. When risky contamination is involved, filtration is not a remedy; it is a mere palliative which serves to diminish not to remove risk. Hence arises the objection to relying for the purposes of health on domestic filtration. Water which calls for such filtration by reason of its being subject to risk of pollution is a water that needs to be replaced by a wholesome supply, and the sanitary authorities of places where such water exists should be pressed to adopt the proper remedy.

#### HOSPITAL MONDAY!

IT looks as if every day in the week, on one ground or another, would soon become sacred to hospitals. Mr. Edward White, in the *City Press*, gravely proposes that a "Hospital Monday Fund" be established with a Metropolitan Hospital Aid League without interfering with either Hospital Sunday or Hospital Saturday. It is really difficult to believe that such a proposal can be meant seriously. It is time to say that this belief in "days" has been carried far enough and that what is wanted is a deeper conviction of obligation on the part of both rich and poor to our hospitals. If Mr. White will persuade—and few men are more likely to do so—both rich and poor to crowd the churches and chapels and other meeting-places of the various religious bodies on Hospital Sunday he will do more to help the hospitals than by the multiplication of hospital days.

#### INTRA-OCULAR AFFECTIONS AS SEQUELÆ OF NASAL DISEASES.

DR. ZIEM of Dantzig publishes in the *Münchener Medicinische Wochenschrift* an interesting case in which intraocular symptoms had supervened on nasal disease. A man sixty-eight years old was suffering from a tumour which obstructed the nose on both sides, especially the left. An irregular excrescence was felt in the left half of the nose, and the left half of the naso-pharyngeal cavity was almost filled by a similar tumour of irregular shape. The left eyelid was tumid and hanging down as if paralysed. The eyeball protruded downwards and was only very slightly movable. The conjunctiva was injected, the pupil dilated and fixed, and partial amaurosis was present in the right eye with venous hyperæmia of the retina and considerable shortening of the focus. The patient, who suffered severe pains in the left eye, begged for its removal, but no operation could have been of any benefit. Injections into the nose helped to remove a large quantity of badly smelling pus and gave the patient great relief, and continued treatment also restored the focus almost to its normal length. In about ten weeks the patient died from the progress of the malignant tumour. The success of the

treatment made it plain that the case was not one of retro-bulbar neuritis, but that the interior of the eye became congested through the swelling of the nasal mucous membrane. In the words of Dr. Ziem the restoration of normal nasal respiration and increase of the respiratory capacity of the lungs re-establish free circulation in the vascular system of the nose and neighbouring organs as well as in the rest of the body; so that after the depletion of the orbits, the eyeball and ciliary bodies, the current of blood becomes normal again within the retina and the ophthalmic nerve and restores the function of these organs.

#### CARRIER-PIGEONS AND VACCINATION.

At the last meeting of the Académie de Médecine, Dr. Hervieux, who presides over the Public Vaccination Department at the head-quarters of that learned body (vaccinations from the calf are performed gratuitously at the building in the Rue des Saints-Pères every Tuesday, Thursday and Saturday) read a report by an army surgeon, M. Stroebel, on the transport of vaccine by carrier-pigeons. It appears that one pigeon is capable of conveying in one journey from five to six tubes. The utility of this means of transport in times of war is very obvious, and one can imagine the joy of the representatives of the Army Medical Department at the apparition of a flock of these swift vaccine carriers in a besieged town.

#### THE FUNCTIONS OF THE PANCREAS.

THE profession is too apt to regard the pancreas as a mere secretor of that composite digestive juice—the succus pancreaticus—forgetting that the gland may have other and equally important rôles to play in the animal economy. The part it takes when diseased in the production of diabetes has for years been insisted on by that careful pathologist and clinician, Dr. Lancereaux, the correctness of whose opinion can no longer be denied after the positive results obtained experimentally by M. Hédon of Montpellier. That gentleman has for some time past been studying the effects of grafting the pancreas of the dog under the skin of the abdominal parietes. His method consists in drawing out the greater part of the gland and fixing it in the subcutaneous tissue, without interfering with the vascular connection between the extruded portion and the part still remaining *in situ*. After the lapse of a few days, this pedicle is cut, and the grafted gland generally continues to live in its abnormal situation. During the first few days of the extra-abdominal existence, the organ swells up, and a tumour is formed which is filled with a clear colourless liquid—the pancreatic juice, in fact. The sac having been emptied a few times, there only remains a fistula through which the liquid continues to flow. Later on, the fistula closes and the graft continues to live, its secreting powers having been suppressed. When the graft is examined no departure from the normal structure of the pancreas is discernible. In the animal arrived at this stage of the experiment there exist then an intra-abdominal and an extra-abdominal pancreas, of which the former remains in connexion with the intestine, pouring into it its characteristic secretion, the pancreatic juice. The extra-abdominal pancreas has ceased to be a secreting organ and has acquired the functions of a vascular gland. Pushed still further the experiment yields most instructive results. The removal of the intra-abdominal pancreas alone is not at all injurious to the dog's health, the urine being normal both in quantity and constitution. When, however, the subcutaneous organ is, in addition, removed, the animal becomes quickly diabetic, the quantity of urine passed being greatly augmented and containing a notable proportion of glucose. Death ensues rapidly. These interesting experiments go to prove that over and above its digestive functions the pancreas is useful and even necessary in other ways.

#### THE DANGERS OF READY-MADE GARMENTS.

No term, perhaps, possesses a more familiar meaning than the word "parasite." Happy, indeed, would be that animal which, however unconscious of etymology, had not the most intimate relation with it. It seems an almost hopeless task to search for this enviable creature. We should despair of finding it even among the animalcula or in the cell world of histology.

"So, naturalists observe, a flea  
Has smaller fleas that on him prey;  
And these have smaller still to bite 'em,  
And so proceed *ad infinitum*."

It is not numbered with the greater beasts. It is not man, whether of high or low degree. The Scottish poet describes, in a humorous poem which is frequently quoted for the pointed lesson it conveys, the career of one well-known parasite which he observed, "plump and gray," strutting on a lady's bonnet at church. A correspondent, writing in a somewhat similar vein, confesses to a like experience. She dilates upon "some exceptionally dainty and befrilled hand-made *lingerie*, snowy, spotless, crisp, and garnished with lace," but, she pathetically adds, with "a something half hidden under a tuck." It was, in her servant's *patois*, a "death louse." Need we be surprised that our correspondent adds to her graphic description the warning that all bought underclothing should before wearing be made to undergo "the full laundry process," the more especially since it appears to be quite customary (may the custom early become extinct!) for firms to send even such articles "on approval" to be tried on? What possibilities does this practice open up, not only of parasitic migration, but of the actual communication of disease. It is a veritable method of infection and it has doubtless acted as such more often than we are aware of. The only real remedy of course consists in its entire discontinuance. Less than this ought not to satisfy a wholesome public opinion. Until, however, the usage of trade in this particular is above suspicion a careful examination and free ventilation of all purchased clothing should not be omitted, while such further measures as "the full laundry process," and, beyond this, antiseptic fumigation, can never be superfluous.

#### MEDICAL NARROWNESS IN SWITZERLAND AND FRANCE.

It is lamentable to think how illiberal the law of Switzerland is in reference to foreign medical men. It is said that an English physician has lately been prosecuted or threatened with prosecution for attending his own mother in a hotel in Switzerland. The Republic of France has passed, or is on the point of passing, a law almost as narrow. The hardship of such legislation is the greater to English-speaking people when we consider the fact that they visit the health resorts of France and Switzerland so freely. It is to the medical men of both countries that we have a right to look for some mitigation of this most unsatisfactory state of the law, and it is certainly they who are considered responsible for it. There is nothing so narrow in our own law. A memorandum has lately been prepared by direction of the General Medical Council for submission to foreign governments, showing the conditions under which foreign medical practitioners are allowed to practise in England as determined by the Medical Acts of 1858 and 1886, and with a view to induce these Governments to reconsider the regulations by which English qualified practitioners are excluded from practising on the Continent even among their own countrymen. Foreign practitioners, though they cannot register or hold appointments, can practise here without restriction so long as they use no name or title implying their registration. Hospitals established for foreigners may be attended by foreign practitioners entitled to practise in their own country and not engaged in other medical prac-

tice. The Act of 1886 goes further. In its provision is made for reciprocity in the recognition of foreign degrees at the instance of the Privy Council, and subject to the approval of them by the Medical Council as furnishing a sufficient guarantee of the possession of the requisite knowledge and skill for the efficient practice of medicine, surgery and midwifery. The holders of such degrees are entitled to registration in the colonial or foreign register.

#### THE HOME FOR EPILEPTICS AT GODALMING.

WE recently referred to the establishment of this home and took occasion to recommend it as an institution calculated to do an immense amount of good. Under the most favourable conditions it was opened a few days ago by the Duchess of Albany. Her Royal Highness was accompanied by Miss Heron Maxwell and Sir Robert Collins. Outside the Town Hall she was presented by the town clerk, Mr. T. P. Whateley, with an address of welcome from the Mayor and Corporation of the borough. A consecration service by the Bishop of Guildford took place in front of the home, in presence of a large company, and the Countess of Meath gave an address in which she explained the origin of the movement and the objects of the home. Dr. Russell Reynolds pointed out how great was the need in this county for some institution such as this and what an amount of good it was capable of doing, while the Bishop of Guildford expressed the satisfaction of the Bishop of Winchester that the house was situated in his diocese. The Duchess of Albany then declared the home open and a vote of thanks was proposed to her Royal Highness by Viscount Midleton. The home—which is to be known as the "Home of Comfort for Epileptic Women and Children"—has been founded by the Countess of Meath, who has taken a fine old house, with ten acres of ground, and has adapted it for the purpose for which it is intended. It is hoped that it will be in every way suitable, and there is every reason to believe that it will. Before the opening there were over 100 applicants for admission and we hope funds will soon be forthcoming to enable the committee to maintain as many free beds as possible. Everything is to be done to render the home bright and attractive and the surroundings pleasant. The inmates will as far as possible be provided with suitable employment, and it is hoped that the work accomplished will materially lessen the expenses. We cordially wish the undertaking all success.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Copenhagen.*—Dr. O. Wanscher has been appointed Extraordinary Professor of Clinical Surgery.

*Halle.*—Dr. Wollenberg has been recognised as *privat-docent* in Psychiatry and Neurology.

*Lille.*—Dr. Morelle has been appointed to the chair of *Materia Medica*.

*Stockholm.*—Dr. Magnus Moeller has been appointed Lecturer on Skin Diseases and Syphilis.

#### DEATHS OF EMINENT FOREIGN MEDICAL MEN.

THE deaths of the following distinguished members of the medical profession abroad have been announced:—Dr. Artigas, Lecturer on Skin Diseases, Toulouse.—Dr. Josef Fischl, *privat-docent* in Medicine in the German University of Prague.—Dr. J. Snydam Knox, Professor of Midwifery in Rush Medical College, Chicago.

AS anticipated in a recent number of THE LANCET (July 9th), the chair of Clinical Medicine left vacant in the Istituto di Studi Superiori of Florence by the death of Dr. Cesare Federici has been definitively accepted by Professor Grocco of the University of Pisa.

THE International Convention of Hygiene at Venice has been followed in Italy by energetic measures for the protection of public health, so imperfectly safeguarded by quarantine. The Director-General of the Sanitary Board has just concluded a visit to Asinara with a view to establishing on that island a number of new disinfecting machines, to be applied to the cargoes of ships hailing from suspected ports.

WE regret to learn that the condition of Sir Richard Owen, K. C. B., the well-known and veteran anatomist, is causing some anxiety. He is over eighty-eight years of age, and though suffering no pain has some indications of failing strength.

THE Lord Lieutenant of Ireland has conferred on Sir Philip Crampton Smyly the well-deserved honour of knighthood. Sir Philip Smyly is the nephew of the late Sir Philip Crampton.

DR. GEORGE FLEMING, C. B., the well-known veterinary surgeon, was on July 30th appointed honorary foreign member of the Académie Royale de Médecine de Belgique.

THE library of the Obstetrical Society of London will be closed from Aug. 22nd to Sept. 22nd.

### THE BRITISH MEDICAL ASSOCIATION. MEETING AT NOTTINGHAM.

WE conclude our report of the proceedings of the British Medical Association meeting held at Nottingham.

#### THE SECTIONS.

##### OBSTETRICS.

##### *The Treatment of Uterine Fibroids.*

On Friday, July 29th, Mr. KNOWSLEY THORNTON opened the discussion on this subject. The treatment of uterine fibroids depended on their structure, situation and symptoms. Those accidentally discovered, which gave rise to no symptoms and were generally from the size of a filbert to a hen's egg, should be left alone. It was even cruel and unnecessary to inform the patient of their existence, as once she knew she had a tumour of the uterus her peace of mind was gone, and she wandered about from doctor to doctor. Attention to food and rest was necessary, with a well-fitted abdominal belt in cases which protruded above the pelvic brim, so as to give support and prevent rubbing of the tumour against the abdominal wall. Iron was generally unsuitable as a medicine, but ergot was of great service. In more severe cases dilatation of the uterine cavity up to No. 16 was of much use. The uterus should be well washed out and swabbed with iodine or hamamelis, and in still more serious cases a free curettage, more especially in the corners of the uterus near the Fallopian tubes, was of great use. Baths were of considerable service; they did good in many cases but they never cured. The foreign baths were preferable to the English ones, as a complete change in every way was desirable. He had no faith in electricity, which had been recommended and practised in so many ailments; in some cases it might slightly improve the patient's condition, but did not answer so well as simpler, safer and less painful methods. If it were capable of curing cases, these should now be reckoned by the hundred. Where were they? Most men who had used electricity had abandoned it. In spite of various treatments a small percentage of cases of uterine fibroids had to be submitted to operation owing to pain, hæmorrhage &c. Vaginal enucleation was unsatisfactory; other fibroids were likely to grow, and its employment should be reserved for those developing into the uterine cavity. Rapid dilatation did good. Mr. Thornton had never used iodoform gauze plugs with success. Two methods of treatment were highly successful—hysterectomy and oöphorectomy. He never decided which he would do until the abdomen was opened; if he found that he could remove every portion of

ovarian tissue he did so and left the fibroids. In these cases the majority were relieved at once and the cure could be absolutely depended on in time. The mortality was only 4 per cent. The patients were kept in bed for three weeks after operation. The best time for operation was a few days after menstruation. The patient had had a rest and was at her best. Where every particle of ovarian tissue could not be seen hysterectomy must be performed, either by the intra-peritoneal method adopted by Schröder, where an elastic ligature was used as a temporary tourniquet and the stump was sewn together, uterine tissue to uterine tissue and peritoneum to peritoneum; this, theoretically, was the best method; but in practice it was found that the extra-peritoneal treatment of the pedicle gave the best results. Mr. Thornton used Kœberlé's serre-nœud. Often a good deal of enucleation was first required; the bladder might have to be peeled off in front and the rectum behind. The wire should be applied about the level of the internal os. The ovaries must sometimes be removed separately, but when they could be left behind he did so, as the removal was unnecessary and interfered with the sexual proclivity of the patient.

Dr. MURPHY thought the Section most fortunate in having had the subject put before them in such a masterly and complete manner. He was in complete accord with Mr. Thornton in everything he said, except that he preferred Tait's clamp to Kœberlé's, and that he removed fibroids by the vagina more frequently than perhaps Mr. Thornton would approve of. A patient had just left the Sunderland Infirmary from whom he (Dr. Murphy) had during the past five years removed four fibroids per vaginam, whilst one had sloughed out of its own accord. He further related the notes of a case where he had removed successfully an enormous fibroid per vaginam that completely blocked the pelvis and reached above the umbilicus. This he was enabled to do by M. Péan's operation of *morcellement*. Having incised the capsule he seized the growth with powerful forceps and removed a portion about the size of a small Tangerine orange with powerful scissors; he then removed another similar portion; and thus, working always from the circumference to the centre, he removed the whole mass in small pieces. M. Terillon had obtained excellent results with a permanent elastic ligature.

Mr. LAWSON TAIT practically agreed with all Mr. Thornton had said, except that he did not attach so much importance to the complete removal of every scrap of ovarian tissue, and he was surprised he had been so lenient on the use of electricity; he himself had spoken very strongly on the subject.

Dr. W. J. TIVY had for five years used Apostoli's treatment in all cases of small bleeding uterine fibroids and was of opinion that it was both a scientific and successful treatment, curing many and diminishing the bleeding in all. In no cases treated by him had it been necessary afterwards to perform hysterectomy or ovariectomy. He applied from six to twelve positive electrifications at first to control hæmorrhage, using from 100 to 150 milliamperes for ten minutes and at intervals of not less than ten days. After the hæmorrhage had been controlled, from six to twelve negative electrifications were suggested, using never more than 100 milliamperes. He advocated the obstetrical position as most convenient and the use of a large Fergusson's speculum when applying the electricity, as permitting a full view of the cervix and a more gentle insertion of the electrode. Aseptic syringing was done before and after each electrification and also daily between the sittings. He used a Gaiffe's galvanometer and a water rheostat, and found forty small modified Leclanché cells with dry elements sufficient to give from 100 to 150 milliamperes. He mentioned three cases.

Dr. HORROCKS had obtained good results from electrical treatment. He had never seen a death from hæmorrhage from fibroid, and he believed the mortality of the operation to be much higher than that of the disease.

Dr. LEITH NAPIER begged to corroborate what Dr. Horrocks had stated with regard to hæmorrhage; great hæmorrhage might occur without fatal results. Sometimes menstruation was unduly protracted, menorrhagia and metrorrhagia continuing as a consequence of the tumour. As to the therapeutic influence of electricity, of which Dr. Horrocks had spoken with some appreciation, it was no doubt true that electricity arrested hæmorrhages in a considerable number of cases; its method of action, however, was probably like that of other intra-uterine counter-irritants, and the benefit derived from its employment was probably

due to the improvement it effected on the chronic endometritis associated with fibro-myomata.

• Dr. MICHIE, speaking from his own observations, had no hesitation in saying that myoma of the uterus, as soon as it gave rise to symptoms, became a serious disease, and should be arrested at once if possible, always provided that reasonably safe means only were adopted to this end; that is to say, he should reserve hysterectomy, for instance, for large and rapidly growing tumours threatening to terminate the life of the patient at an early date. Although no doubt it did at times happen that the disease was arrested or cured by nature at the menopause, he had not yet seen such an event, but he could recall to mind at least four cases that ended fatally in one way or another as the result of myoma of the uterus. He had seen only very temporary benefit from any form of dietetic or medicinal treatment and that only in so far as the hæmorrhage was concerned. He considered, however, that in the operation for the removal of the appendages, if properly and completely performed, there was a method of dealing with this disease attended by the happiest results.

Dr. ELDER said that in the main he agreed with the remarks made by Mr. Knowsley Thornton on the treatment of uterine fibroids. For a very considerable period of time after visiting Apostoli's clinique he gave the treatment a fair trial, and must confess that his first impressions were distinctly favourable. In the majority of cases it proved an efficient hæmostatic; the pains were relieved and the general condition of the patients was marvellously improved. But even at that early period it was found that now and again cases presented themselves which the treatment totally failed to influence. Still, on the whole the results were so encouraging that for nearly two years he pursued the treatment, and only finally abandoned it as a routine practice on finding that, in addition to being uncertain and tedious, the permanence of its good effects could not be relied upon.

Mr. STANMORE BISHOP remarked that it was generally admitted that of the two methods of dealing with the stump in supra-vaginal hysterectomy, the intra-peritoneal, or, as Dr. Priestley Smith called it, the sub-peritoneal, method was ideally the best, whilst statistics unhesitatingly declared that the extra-peritoneal method was practically the safest. Any detail, therefore, that would tend to render the former operation safer was worthy of consideration. The dangers which beset a patient after intra-peritoneal treatment of the stump were twofold—secondary hæmorrhage and sepsis. In these days the temporary elastic ligature allowed sufficient time for the surgeon to secure the vessels involved, and it was seldom that much anxiety arose from this source; but the danger from sepsis was far more subtle. It was taken for granted that all the usual precautions were taken, but there always remained one source which it had been so far impossible absolutely to guard against—the mucous surface of the cervical canal. Many methods had been devised to get rid of this risk. After removing the body of the uterus through the abdominal opening, one surgeon removed the cervix by vaginal hysterectomy, another removed the entire uterus by laparotomy, another cauterised the cervical canal with pure carbolic acid, whilst another, after carefully suturing the flaps together, left these sutures long, and opening Douglas' pouch, passed them into the vagina, drawing down and inserting the stump through this. The modification he would suggest was: laparotomy, with delivery of the tumour through the abdominal opening.

#### *Anatomy of the Hymen.*

Dr. CULLINGWORTH read a Note on the Anatomy of the Hymen and on that of the Posterior Commissure of the Vulva, in which he maintained that the ordinary text-book description of the hymen was erroneous, and that the hymen of the adult virgin normally consisted, not of a fringe of membrane surrounding a circular or oblong aperture with its edges lying apart, but of a long vertical fold of mucous membrane with its edge (when a patient is lying in the dorsal position) directed forwards, and divided, along about three-fourths of the summit of the fold, by a vertical slit. This slit constituted the orifice of the vagina. Normally no actual opening was seen either into the vagina or into the urethra. The orifices of both were vertical slits, bordered by lips, the inner surfaces of which were in close apposition and the edges of which were like those of the labia minora, directed forwards. The point had a very important practical bearing, for it was the anterior extremity of this hymeneal fold that, being prolonged forwards and partially concealing the aperture of the urethra,

constituted that fleshy caruncle which was recommended as a guide to the urethra when passing the catheter. It was obvious that when, from any cause, the vaginal orifice had become dilated the relations of the hymeneal fold would be permanently disturbed and its anterior apex could no longer be relied upon as a landmark. The only reliable guide to the urethra was obtained by passing the forefinger of the disengaged hand into the vagina and placing its palmar surface against the anterior wall, where the urethra could be felt as a cord-like prominence imbedded in its tissues. This method not only had the merit of being universally applicable, but had the further advantages of preventing the slipping of the catheter into the vagina, of avoiding the contact of the finger with the sensitive parts in front of the urethra and of enabling the finger to feel and direct the instrument in its course along the whole length of the urethra. In his twenty years experience as a gynaecologist Dr. Cullingworth had never yet seen a case where the hymen was absent, or even where it failed to be easily demonstrable. Occasionally the lips of the hymen were so deeply notched laterally that the edges came together in a cruciform manner. A cribriform hymen he had never seen, and he did not believe that it existed. In the latter part of his paper Dr. Cullingworth confirmed from clinical observation the statement of Luschka that the structure of the fourchette, or anterior border of the perineum, was continuous with that of the labia minora and not of the labia majora. He also called attention to the fact that the duct of the vulvo-vaginal, or Bartholin's gland, did not, as was often asserted, open into the fossa navicularis, but by the side of the vaginal orifice in the groove between the attached border of the hymen and the labium minus, a little nearer the vestibule than the fourchette.

#### PSYCHOLOGY.

##### *Reaction Measuring.*

Mr. BEVAN LEWIS, President of the Section, described in detail an improved instrument for measuring reaction-time, and explained the various improvements. The object of these was to enable a very slow reaction time to be correctly measured, and he considered that he could now accurately measure any period of time up to one second within the one-hundredth of a second. Another feature was the noiseless release of the rod which gave the signal; this was suspended by an electro-magnet instead of by a hook, as in the old instrument, and the remainder of the rods used in measuring the time were severally suspended by electro-magnets, each being successively liberated by the preceding rod breaking the current as it fell. Mr. Lewis said that Dr. Bedford Pierce had assisted him in certain details.

##### *Paranoia and its Relationships.*

Dr. E. L. DUNN read a paper on Paranoia and its Relationships. He gave an abstract of the French and German opinions and descriptions of paranoia, and described in detail the variety paranoia persecutoria, giving the three stages of this disorder, and discussed the diagnosis between it and melancholia. This he summarised by saying that in melancholia a patient thinks he suffers justly on account of his wickedness, whilst in paranoia persecutoria the patient thinks he is a victim and suffers from no fault of his own.

Dr. HACK TUKE alluded to the destructive criticism which the German term "Primäre Verrücktheit" had received, and now the word "paranoia" had been substituted. He said the clinical descriptions given abroad of this condition were very conflicting. Even the three stages were very variably described, and he doubted whether they were at all constant. He thought the term ought to be avoided, at any rate for the present, and that the older name, "systematised delusion," was much better; but he would prefer still to use the English nomenclature and include all similar cases under the head of delusional insanity.

Dr. MICKLE said he, in the first place, divided such cases into the expansive and depressed, which groups were subdivided further. In his opinion the majority of cases did not follow the course described, though in a small minority the description was accurate. Generally megalomania was earlier evolved than in the description given. He considered that some cases of paranoia eventually recovered.

Mr. RICHARDS deprecated the use of fresh names, and wanted to know why we do not stick to our Anglo-Saxon. He thought that if we divided and subdivided in this way it was *prima facie* evidence that we knew very little about the conditions in question.

Dr. RAYNER thought the general health of such patients was on admission generally imperfect, and he ascribed much of the subsequent feelings of well-being to improved general health.

Dr. GOODALL thought paranoia was a good name for systematised insanity of the type described, and that it would be helpful to students in distinguishing it from conditions superficially resembling it.

Mr. BEVAN LEWIS said it was a good tonic to be in good company, and that he always had an English prejudice against the term. He fully recognised the conditions described, but included it in delusional insanity. He stated that in all forms of insanity there was present an affective disorder, and that with depressed object consciousness there is a rise of subject consciousness. In most cases the parentage was of great importance, for such patients inherited a negative condition of mind in which violent outbursts could not readily arise, but in whom systematised delusions were easily developed. He would look for typical cases in prisons rather than in asylums.

Dr. DUNN then replied. He stated that he had collected the literature of the subject in order to ventilate the question and to hear the opinion of others, and he still thought that the word "paranoia" was of value to describe the limited group of symptoms that he had detailed, and defended its use in this limited sense.

##### *Insanity as a Plea for Divorce.*

Dr. WEATHERLY then read a paper opening the subject for discussion—viz., Insanity as a Plea for Divorce. He began by saying that in a discussion upon this subject which took place ten years ago he expressed opposite opinions to those he now holds, and that ten more years of asylum practice had shown him much that had modified his views. It was very rare that insanity in the eye of the law could be proved, even though the person might be certifiable as insane. He then denounced the withholding from anyone about to marry the fact that the other had been insane or came from a stock insane or otherwise unsound. He considered that such marriages were fraudulent, but as the law now stood it was impossible to dissolve the marriage. With regard to the question whether insanity occurring after marriage should ever be a plea for divorce, he summed up the leading objections under four heads, which he severally discussed: (1) That in nearly all cases the prognosis presents some doubtful features; (2) that the marriage service, where it says in sickness or in health, represents the sanctity of the marriage contract; (3) that it might be argued that if in one disease divorce is justifiable, why not in others, such as cancer or phthisis? (4) that it placed undue responsibility upon medical men.

Mr. STEWART (Clifton) said the word "incurable" should be inserted. It must be understood that incurable insanity is referred to. He thought that legal authorities would require much evidence to establish incurability and that a longer time should elapse than seven years—he would suggest ten years—before proceedings could be instituted. He thought every case should be examined by a medical expert appointed by the Government.

Dr. RAYNER was convinced that insanity should never be a plea for divorce, and that the existing law tended to a careful examination into the history of disease before marriage.

Dr. HACK TUKE sympathised strongly with the preceding speaker and said he could not go further with Dr. Weatherly than the remarks he made in reference to what he had rightly termed fraudulent marriage.

Dr. SUTHERLAND thought in any case the question should be considered by medical experts.

In reply, Dr. WEATHERLY was very glad that the meeting had agreed with him on the first two points he had proposed for discussion. He emphasised his original proposition that insanity might become a plea for divorce, and not a warrant for wholesale dissolution of marriage. He asked that the President should take the opinion of the meeting on the three questions he had raised, which was done, and it was found that the first two were decided without any dissentient: (1) that divorce could be granted in all cases in which one of the contracting parties at the time of marriage was certifiably insane; (2) that all cases of fraudulent marriage, as described in the paper, could also be rendered void. On a vote being taken upon the third question, whether incurable insanity after examination by experts appointed by the Government be a legitimate plea for divorce, it was decided in the affirmative by 17 to 13.

*Acute Encephalitis.*

Dr. GOODALL read a paper entitled *Notes on the Pathological Anatomy of Acute Encephalitis*. This paper contained an account of certain preliminary experiments, undertaken with a view to determine the nature and relationship of the spider-cell element of the connective tissue of the brain. Incidentally the alterations undergone by the nerve cells in acute encephalitis were touched upon. The author employed rabbits in these experiments, producing cerebral irritation by puncture of the brain with a platinum needle and by application of dilute cantharidin to the pia mater. Staining of the sections was chiefly performed with aniline blue-black and they were cut by the fresh method. Thus the spider cells were particularly well brought out. The chief results and conclusions reached were as follows: The morbid development of spider cells proceeded in a particular order; the first to show signs of growth were the subcortical ones, next came those between the pia mater and the cortex, then those of the outermost layer of the cortex, and lastly those situated in the rest of the cortex starting in the deeper parts. Apparently the most prominent in health were the first to show morbid growth in inflammation. The author stated reasons which led him to conclude that the spider cells of inflammation were developed from pre-existent cells and not from leucocytes, at any rate in the earlier stages of that process (up to the end of the first week). Even at the end of the twelfth day he had been unable to satisfy himself of the leucocytal origin of the spider cells. As long as the theory of the development of the connective tissue of the brain from leucocytes remained a possible one it would be difficult to deny the possibility of a leucocytal origin for these cells in inflammation. His experiments appeared to show that the fixed connective-tissue cells were in large measure the progenitors of the spider cells seen in the diseased cortex of general paralysis and alcoholism.

*Hypnotism.*

Dr. LLOYD TUCKEY gave an abstract of a paper upon the Value of Hypnotism in Chronic Alcoholism. He reviewed thirty-one cases of chronic alcoholism he had treated with post-hypnotic suggestion. He had had three successful results in cases of over two years' standing, five in cases of over one year's standing, and five patients, some of whom are still under treatment, are better. In some the influence was nil; in others relapses occurred. He came forward as a general practitioner and claimed that hypnotism should take its place in therapeutics by the side of other agents, such as massage and hydro-therapeutics. He was quite satisfied that a certain proportion of cases were cured. The only alternative treatment was confinement to a retreat which not only broke up the home, but tended to induce a habit of loafing and idleness. He said that casual hypnotisation was quite useless and that regular treatment under supervision for a month was necessary to success. He related two cases in low-class women who eventually relapsed. He had seen no ill effects from the practice of hypnotism by qualified persons.

Dr. ROBERTSON followed with a paper upon the Use of Hypnotism in the Insane. After describing several cases, giving reasons for its use, the following summary of its use among the insane (excluding physical diseases) was given:—  
A. It may be used as a direct therapeutic agent: (1) in insomnia success may follow in intractable cases, where drugs have not succeeded, hypnotic sleep being a more natural sleep than that induced by drugs; (2) as a sedative in excitement, it may be here of direct therapeutic value in preventing an outburst of excitement from passing into mania in a brain which is in a highly unstable condition; (3) to dispel fleeting delusional states and the minor psychoses. The lesser degrees of mental derangement having been entirely removed by suggestion. B. It has indirect therapeutic uses for purposes of management: (1) to overcome the morbid resistance of patients for their own benefit, as in taking medicine or food; (2) as a substitute for restraint, where it may be of great value in controlling violence, a mental restraint being substituted for mechanical or chemical restraint.

In the discussion which followed, Mr. DRAPER said he had used hypnotism in general practice for some years. In five or six cases he had seen the pain of labour disappear and unconscious delivery result under the influence of hypnotism. He had been able to delay sending recurrent cases of insanity to the asylum and had also treated successfully a case of epileptic insanity by hypnotic suggestion.

Dr. HACK TUCKEY alluded to Dr. Percy Smith's cases at

Bethlem Hospital upon which hypnotism was practised and was found not to have any value, but he thought it quite possible, under more favourable conditions, the result might be different. He also mentioned some cases in Switzerland in which hypnotism had been of value.

Dr. BEDFORD PIERCE said he did not wish to criticise in any hostile sense, but would like to ask Dr. Tuckey if he thought his percentage of cures was any greater than that obtained in an average Salvation Army meeting. It was well known that cures were so obtained; but without touching upon the religious side of the question he doubted whether Dr. Tuckey's care, advice and attention had not more to do with the recovery than hypnotism.

Mr. STEWART criticised the use of hypnotism in chronic alcoholism and thought the proportion of recoveries quoted by Dr. Tuckey was too small to warrant much in the future. He questioned whether hypnotism ever assisted the will power to recover, but it might facilitate the natural means of recovery by helping for the time the patient's resistance to temptation.

## THERAPEUTICS.

*Discussion on Anæsthetics.*

Dr. DUDLEY BUXTON opened a discussion upon the "Anæsthetic Action of Chloroform viewed from the standpoint of recent Physiological and Chemical Research." He said that at no time more than the present was attention directed to anæsthetics, for while opinions might differ as to the action or merits of this or that anæsthetic, there was unanimity as to the importance of a more accurate and exact knowledge of the subject. He indicated that accidents occurred under chloroform in several ways and were attributed to various causes by different observers. The phenomena of these accidents he proposed to examine, and, as far as possible, to indicate the physiological facts which underlay them. Deaths were reported to take place from the following causes. 1. Before an operation had commenced, when they were variously referred to fright; reflex inhibition of the heart's action conveyed from some sensory nerve and through the vagus; syncope brought about through direct action of the chloroform itself, or possibly of some impurities contained in it; through interference with respiration arising from mechanical causes—e.g., the constraining effects of tight clothing, voluntary holding of the breath or spasm of the larynx &c. 2. During an operation, they were then attributed to shock—either simple, the direct effect of the operation upon an imperfectly anæsthetised subject, or shock as understood when surgical procedure was so severe as to make itself felt through chloroform anæsthesia properly and thoroughly established. Deaths were also reported as being due to direct syncope, on the one hand, or to failure of respiration on the other. These cases were attributed by some to nervous origin—action of chloroform upon the medullary centres—respiratory failure being primary and cardiac failure being secondary; while, on the other hand, it was thought by others that there was an initial action on the heart muscle leading to respiratory failure as a secondary result. 3. Deaths occurring after the operation was completed were in some instances attributed to the effects of the anæsthetic. Passing to the physiological side of this question, Dr. Dudley Buxton said that experiment upon the batrachian and mammalian heart muscle had shown that both the vapour and dilute solutions of chloroform were able to completely paralyse it, causing it to lose alike its contractility and irritability; but it might be said that either intravenous injections or inhalations of chloroform could never so act upon the human heart, because before sufficient chloroform had entered the circulation death from respiratory paralysis would have occurred. However, this argument had been shown to be invalid, since Drs. Gaskell and Shore had proved that when blood laden with chloroform entered the medulla and circulated through the respiratory and other centres the blood pressure did not fall, whereas when the chloroform perfused the heart but was excluded from the nervous system blood pressure rapidly fell. Again, the direct proof of the action of chloroform upon the heart muscle had been demonstrated by the researches of Dr. MacWilliam and other observers, who had found that repeated inhalations led to degenerative changes in the muscular fibres of the heart. It had been attempted to prove that impurities in the chloroform were responsible for the toxic effects of that agent. Upon this point he thought the work of Professor Du Bois Reymond, jun., had failed to establish that ordinary

impurities actually increased, much less caused, the lethal effects of chloroform. How far the nervous system was the origin of death under chloroform was then considered. So-called "reflex death" was probably seldom, if ever, brought about. Professor Wood's experiments had shown that liquid chloroform poured into the larynx when that structure was separated from the trachea, although it was in nervous communication with the medulla, did not materially affect the heart. The experiments of the Hyderabad Commission showed further that vagal inhibition following sensory stimuli is most rare in the lower animals, and the same applies to shock. The experimental evidence would here appear to be in conflict with that advanced in clinical records; and this was pointed out as a reason for not accepting as proved for human beings what was shown to occur in lower animals, unless corroborative proof, either actual or inferential, existed for human beings. The researches of Drs. Gaskell and Shore were taken as proving that the toxic effect of chloroform was less pronounced upon the nervous system than upon the heart. The fall of blood pressure, usually accepted as a sign of vagal action, had been shown to be a more complicated matter, since it occurred when the nervous system was intact and not when it was under the influence of chloroform. It thus appeared that of the deaths grouped under (1) fright possibly acted in some cases in human beings, but never among the lower animals; reflex inhibition of the heart among human beings possibly occurred, but never in the lower animals; mechanical impediment to breathing probably acted both in the lower animals and in man; likewise direct action of chloroform upon the heart was demonstrable in man and in the lower animals. In the last case the actual dilatation of the viscus could be seen, while in the former symptoms existed which were explicable by such an anatomical change taking place. To the deaths grouped under (2) much of what has been said already applied with equal force. It must be added that in the case of the lower animals shock, hæmorrhage, operation, and so on, appeared to have less effect than in man. Of cases coming under (3) the experimental evidence which seemed to indicate a progressive impairment of the muscle of the heart appeared to explain post-operation deaths occurring with the symptoms of syncope after some hours of resumption of consciousness. Such cases were hardly to be explained under any other hypothesis.

Mr. JOSEPH WHITE, F.R.C.S. Edin., President of the British Medical Association, dwelt upon the importance of the subject. He had carefully studied it for many years. He gave his personal observations upon the size of the pupils under chloroform, believing that when they could be kept fairly contracted the patient was in safety.

Dr. LAWRENCE TURNBULL (Philadelphia) addressed himself to his own and his fellow countrymen's experience upon the relative safety of anaesthetics. He read an interesting report of the way in which patients were anaesthetised in the Johns Hopkins clinics.

Dr. FREDERIC HEWITT acquiesced in Dr. Dudley Buxton's conclusions. He felt strongly that very many of the phenomena met with constantly when human beings were chloroformed were not reproduced when looked for among the lower animals—fright and dread of death were absent from these. He thought vagal influence could not be explained away in human beings, and he described some cases in which vagal inhibition appeared.

Mr. ROWELL spoke upon Dr. Kirk's "theory" of chloroform poisoning, and suggested that in cases of impending death under chloroform a valvular opening should be made below the cardiac apex and the heart rhythmically grasped by the sterilised hand and emptied so as to maintain the circulation.

Mr. RUMBOLD, from an experience of 400 cases of administration of nitrous oxide extolled its merits in minor surgery. He exhibited an apparatus.

Dr. RALPH STOCKMAN had used samples of chloroform rejected as "bad" by the makers for anaesthetising animals, and his experience led him to think that impurities played little or no part in chloroform deaths.

After a few words from the CHAIRMAN, and a brief reply from Dr. DUDLEY BUXTON, the discussion closed.

#### EXHIBITS.

THE Exhibition of Foods, Drugs and Medical and Surgical Appliances was a very interesting one and attracted a considerable number of visitors. In the centre of the

Museum were to be seen the pharmaceutical products manufactured by Messrs. Oppenheimer, Son and Co., Limited, which comprise palatinoids, bi-palatinoids, concentrated liquors, cream of malt preparations, &c. Numerous specimens of palatinoids were displayed and great interest was shown in the formation of pure ferrous carbonate, phosphate, arseniate and the hypophosphites in the bi-palatinoids. Among other preparations we noticed the cream of malt oil and hypophosphites, a preparation which has proved very useful in the treatment of wasting diseases; also their concentrated Liquor Euonymin et Pepsinæ Co.; and Liquor Caulophyllin et Pulsatillæ Co. Their exhibit was one of the largest in the Museum. The 150 microscopes used in the demonstrations included in Section B in the department of Pathology were supplied by Mr. Robert J. Beck. This firm also showed an improved form of their star microscopes with the addition of an Abbe condenser on a swinging arm; also their new microscope, with an improved sub-stage, new air-tight capsules for cultivation and for mounting specimens, razor-stropping machines and compact microtomes, &c. Mr. Helbing's selection of pharmacological preparations excited considerable attention. In this exhibit were drugs derived from the distillation of coal-tar and other productions for which this firm is well known. The Amidjah fire escape is the invention of Mr. Lewis Amidjah, first introduced in 1888 at the Fire Rescue Exhibition held at the Portman Rooms, London, which was arranged by Dr. Danford Thomas to bring to public notice inventions having for their object the prevention of fire and the saving of life from fire. This invention has been introduced into St. Mary's Hospital, the Hospital for Sick Children and other benevolent institutions, and has secured the commendation of authorities in barracks and other Government buildings. Root's Cuca Cocoa and Chocolate, also Bush's Liquid Beef, a concentrated raw food, condensed by an entirely new process which preserves all the nutritive principles of carefully selected beef, were exhibited. Samples of water from the Flitwick chalybeate spring in Bedfordshire were shown, an account of which was published in THE LANCET of Oct. 24th, 1891. The preparations of the Maltine Manufacturing Company, Limited, in conjunction with Carrick and Co., were exhibited. Their well-known combinations with maltine were shown, such as those with cod-liver, lime, pepsine &c., and other useful forms of food for infants or invalids. The exhibit of Messrs. Hurst and Co. of Great Tower-street was interesting from the fact of its comprising specimens of batteries in a modified form for the supply of electricity for medicinal purposes. This firm dispenses with the primary acid battery, with its many disadvantages, and substitutes either dry Leclanché cells or accumulators. These are supplied in a neat and portable fashion for either cauterly or lighting purposes. A large collection of galvanometers, rheostats &c. were also on view. An apparatus for examining the keenness of eyesight by the unexpected and quite accidental appearance of various test types was much noticed. The illuminating instruments comprised an improved form of photophore, which permits of examinations being made in daylight, and several instruments for internal illumination on rather a novel principle, by which the diseased parts of the body are made transparent and allow of external examinations. The stall supplied by Messrs. Allen and Hanbury was furnished with a specimen of Mr. Emile Andreoli's apparatus for the generation of ozone, the production of which has until lately been attended with great difficulty. This firm also exhibited a series of foodstuffs to meet the requirements of infant feeding during the various stages of development of the assimilative function. Among the general exhibits the byno-hypophosphites attracted considerable attention. Messrs. W. H. Bailey and Son had a capital display of silk, cotton and elastic stockings of fine texture, hardly to be distinguished from ordinary fine hose, and yet affording efficient support. They also showed clinical thermometers which have been certified at Kew, and an excellent collection of trusses, abdominal belts so constructed that "rucking up" is entirely avoided, and steel wire braided pillows and cushions. The American Braided Wire Co. had a choice selection of their goods; and Mr. F. J. Robman showed some physiological models. The tabloids of Messrs. Burroughs and Wellcome were well displayed, and their merits and variety excited great interest. Messrs. Downs Brothers exhibited Samway's tourniquet clips in various patterns, an improved ophthalmoscope, and a new splint for the treatment of fractures of the elbow-joint. The pulver-

flator, an instrument for use in naso-pharyngology and dermatology, was shown by Messrs. McKesson and Robbins, New York. (This invention was described more fully in our issue of last week.) They also showed their preparations of the stearate of zinc in combination with various drugs. The stearate differs from the oleate in being made from suet instead of oil.—Woods' patent invalid bedstead and other appliances were exhibited by the Longford Wire, Iron, and Steel Company, Limited. A stall was also occupied by the Liquor Carnis Company, who had a large display of their patent foods. The exhibit of Messrs. Parke, Davis and Co.'s products were of a varied nature: a small assortment of fluid extracts, gelatine and sugar-coated pills (oval and round) in many colours, tablet triturates, and a pepsin which they label and sell as one grain, capable of dissolving 4000 grains of albumen, according to the usual test for showing comparative strength of pepsin. For this purpose a unique pepsin tester was in working order on their exhibit table. This tester is made to work automatically by the use of a small stream of water and is intended to show the different strengths of pepsin under similar circumstances. They also exhibited Weld's syrup of chloride of iron and Mosquera's beef products. The practical use of the Remington typewriter was demonstrated by Mrs. Marion Marshall, and a large number of the members of the Association availed themselves of her aid. Hartmann's Sanitary Wood Wool Company, Limited, exhibited their well-known preparations, including wood wool wadding and tissue, which are now used in almost every hospital in the United Kingdom; also their Hartmann's hygienic towlelettes, largely used after accouchement as well as for ladies' general use, and Hartmann's guinea accouchement outfit, which contains all the necessary sanitary appliances and is claimed to afford a great saving of time and trouble in supplying to young mothers the various articles they require for the time of confinement. A new revolving operating table was exhibited by Mr. John Carter. This table can be fixed at any angle or detached and used as a stretcher. Mr. Carter also exhibits the "Stanmore Bishop" hip-disease bed which was devised for use in severe cases of morbus coxæ, but is also useful for any condition in which prolonged confinement to bed is required, as the patient can constantly alter the plane of pressure. Messrs. Krohne and Sesemann exhibited their Hyderabad chloroform inhaler, the regulating inhaler and many others.

### THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE ANNUAL MEETINGS OF FELLOWS AND MEMBERS.

It will be in the recollection of our readers that the proceedings at the annual meeting of Fellows and Members of the Royal College of Surgeons of England, held on the 5th of November, 1891, and the subsequent delay of the Council to return an answer to the request of the meeting, "that a copy of the Report of the Council should be sent by post to each Fellow and Member a fortnight before the annual meeting," led us to entertain the fear that the Council might be induced to abolish the annual meeting altogether. The extreme brevity of the reports of the proceedings of the Council of the College which are vouchsafed to the Fellows and Members prevents the profession from learning the nature of the discussion which took place in the Council on the 1st inst. on the question of holding the annual meeting of Fellows and Members of the College in November next, and to what extent our fear was well grounded. We are glad, however, to be able to congratulate the Council on the result of their deliberations, and to learn that it was agreed that the annual meeting of Fellows and Members of the College should be held on Thursday, Nov. 3rd, at 3 P.M., and that the usual notices should be issued. A contrary decision would have been derogatory to the dignity of the Council and have placed it in a false position. The annual meeting of Fellows and Members was instituted deliberately by the Council in 1884 in response to a resolution unanimously passed by a general meeting of Fellows and Members and from a conviction that it was right to place before the members of the Corporation once a year the record of the proceedings of the Council, and

to afford them an opportunity for criticism and an expression of opinion on the management of the affairs and finances of the institution. The mere facts that this criticism occasionally exceeds the limits of propriety and good taste, and that the voluntarily assumed attitude of the members of the Council who group themselves in the well of the theatre and constitute a butt for the shafts of the assembled Fellows and Members is not altogether as pleasant as they would wish it to be, are not sufficient reasons for cancelling the conceded privilege. Men who hold public offices must not be too thin-skinned and wince under criticism, just or unjust. To any misrepresentations and attacks it is open to the members of the Council to reply at the time and any irregularities can be checked at once by the President. To deprive the great body of Fellows and Members of the privilege of reviewing the proceedings of the Council and making suggestions for the more efficient administration of the affairs of the College on account of the ebullitions of a few ill-regulated spirits would be inexpedient and unjust, and would amount to an open confession of inability on the part of the Council to maintain order. It would be playing the part of rulers whose only remedy for disaffection is to "make a solitude and call it peace." Happily, the Council of the College have decided—if not unanimously, at least by a majority—to meet the Fellows and Members as usual, and we shall be greatly mistaken and disappointed if the tone and conduct of the general meeting in November be not such as to convince the members of the Council that their decision has been a wise one. The settlement of the recent action in the Court of Chancery has removed a cause of irritation on both sides and ought to lead to the establishment of friendly relations between the Council and the Members of the College. If the spirit of distrust of the constituency is laid aside, and if the Fellows and Members are called together by the Council with a sincere desire to consult them and meet their wishes so far as is compatible with the fulfilment of its obligations and the honest convictions of its members, the meeting in November may prove a fresh starting-point—the closing of an old chapter of disunion and conflict and the commencement of another chapter of unity and concord. The preparation of the annual report, we observe, has been entrusted to a committee, and we presume that this committee will consider the request of the last annual meeting that a copy of the report of the Council should be sent by post to each Fellow and Member a fortnight before the annual meeting. If the Fellows and Members of the College as a body were in the habit of studying the calendars of the College or keeping themselves acquainted with the progress of affairs by reading the published minutes of the Council, it would be unnecessary to circulate the report beforehand; but this duty is so often neglected or interfered with by the pressure of daily practice that it is desirable to leave the Fellows and Members of the College without excuse for ignorance of the events of the year and for maintaining that apathy and indifference which are the sole obstacles to their securing their proper weight in the administration of collegiate affairs. The cultivation of an interest in the progress and wellbeing of the College on the part of the Fellows and Members should be one of the deliberate aims of the Council, for it would strengthen the hands of the executive and tend to enlarge the usefulness of the College as a scientific institution. We should therefore consider that £50 or even £100 spent in the circulation of the report would be well spent, even if it should be like bread cast upon the waters and only found after many days. A more immediate return might in all probability be the effect of the distribution—the diffusion of a spirit of loyalty and contentment with a council which responds so promptly to the wishes of its constituents, and a quickened interest in the institution itself, manifested, it may be, in due season by a better attendance at the lectures of the College and more valuable donations to the museum and the library.

### THE AMERICAN MEDICAL ASSOCIATION.

#### [SECOND NOTICE.]

In the previous notice of the important meeting at Detroit of this Association we gave a short account of the general addresses which were delivered; but the chief scientific interest of the meeting was centred in the matters discussed in the various sections. Of these there were in all

twelve—viz., Surgery and Anatomy, Practice of Medicine, Obstetrics and Diseases of Women, Neurology and Medical Jurisprudence, Ophthalmology, Laryngology and Otology, Materia Medica and Pharmacy, Physiology and Dietetics, Diseases of Children, State Medicine, Oral and Dental Surgery, and Dermatology and Syphilography. Although the attendance at all the sections cannot be said to have been large, at most it was satisfactory, and at some both the attendance and the interest in the proceedings were all that could be desired.

At the sectional meetings of the first day no subject of very engrossing interest came up for discussion. An important address was delivered by the chairman in the State Medicine Section dealing with the responsibility of the National and State Governments for the protection and purity of water supplies. The importance of the purity of a water-supply to a community was pointed out, as well as the neglect and laxity which had been observed up till recently with regard to it in America, and in conclusion an energetic plea was urged that in dealing with this question local and political jealousies and inherited prejudices should be subordinated to the higher considerations of the interests and happiness of human life.

In the Section of Diseases of Children in the course of a paper on Scorbutus in Children, Dr. Brush made a strong protest against the too common departures from natural feeding in the case of infants and children. His argument was based upon the statement that every living creature requires some raw living food and he regarded sterilisation and such processes as likely to deprive aliment of some of its necessary qualities. But he certainly overstated his argument when he implied that scurvy is the result of the deprivation of fresh living food. Surely he must have forgotten that vegetables are as a rule boiled before they are eaten, and they can scarcely be imagined to retain their vitality after the fiery ordeal.

A paper which evoked some discussion in the Neurological Section was that of Dr. Chaney of Michigan on Responsibility in Will-making. He referred to numerous cases which had recently occurred involving the question of testamentary capacity, and in criticising them he called attention to the unsatisfactory legal definitions of insane delusions as well as to the doubt which existed as to the effect of various disturbed psychical conditions on testamentary capacity.

Perhaps the most interesting paper on the second day was that of Dr. Rockwell of New York on Electrical Execution. Dr. Rockwell may be regarded as an authority on this subject, for he was one of a commission of three appointed by his State to determine whether disfigurement by heat or chemical action was likely to be a result of execution by electricity. From the numerous experiments which he made upon animals, and from his experience of electrical execution so far, Dr. Rockwell is firmly of opinion that this mode of execution is at once the most instantaneous and the least objectionable in all other respects. The same position was taken up by Dr. Fell in his communication on the same subject and he advocated this mode of execution as the least objectionable in every way. As is well known, these are not the views held by THE LANCET on this subject.

On the third day of the meeting, among the papers which had most interest was that of Dr. Shepard of Brooklyn, urging the more general employment of baths and pointing out their efficacy as a preventive of disease. This paper was read at the State Medicine Section, and excited a good discussion. The general opinion seemed to be in favour of the establishment of public baths on a large scale. At the Neurological Section the paper which excited most interest was that of Dr. Dewey.

Reference has been made to but a few of the numerous and interesting papers which were read. Enough, however, has probably been said to indicate the valuable nature of the contributions as a whole and the stimulus which was sought to be given in the general addresses. American science is young, but it is vigorous, and if it is a little narrow and provincial in the conception which some of its exponents have of its functions, that is a fault which will almost daily diminish. The advances which are being made in every direction, thanks to the opportunities which the munificence of its millionaires have made available, are beyond all parallel remarkable, and it augurs well for the future of American medicine that such keen and universal interests should be evoked as were evident at this meeting.

The exhibits of medical books, instruments and appliances

generally were extensive and varied. Preparations of all kinds of drugs were displayed in various forms, and one of the most interesting "shows," if we may use the word, was the manufactory of Messrs. Parke, Davis and Co., who gave every facility to the members of the Association to visit and inspect their laboratories.

The social side of the meeting was of the usual kind. There were a few dinners of Sections; there were receptions by the medical men of Detroit and by others, and an excursion on the Detroit River and Lake St. Clair afforded much pleasure, if it did leave the Sections to languish a little. In short, everything which the people of Detroit could do was done, and with a heartiness and geniality which enhanced the hospitality.

## ARMY MEDICAL DEPARTMENT REPORT FOR THE YEAR 1890; WITH APPENDIX. VOL. XXXII., 1892.

[THIRD AND CONCLUDING NOTICE.]

As regards the vital statistics of the British Army in India the following table embodies the facts and ratios for the three Presidencies.

	Average annual strength.	Ratio per 1000 of mean strength.				
		Admitted.	Died.	Invalld home.	Invalld discharged.	Constantly sick.
Bengal.. ..	41,143	1589·5	10·18	25·18	17·16	89·16
Madras .. ..	18,551	1409·2	18·07	22·95	15·05	88·71
Bombay .. ..	12,762	1898·4	10·35	28·83	18·40	78·00
Total .. ..	67,456	1517·1	14·45	25·42	16·09	86·06
Ten years 1880-80.	507,058	1470·0	15·06	27·00	13·53	71·17

In Bengal the loss to the command by death and invaliding was 1673, being at the rate of 40·66 per 1000, and the loss to the army by death and final discharge as medically unfit for further service was 1372, equal to 33·34 per 1000, an increase of 4·09 on the return of the previous year. The highest admission rate was among men in their second year of service in the country. The mortality ratio was high among men in their first year of service, fell during the second, and fell still further during the third year of service, after which the rate of mortality increased and kept increasing up to over ten years' service in the country.

As regards enteric fever, it occupies much the same prominent position as a cause of sickness and mortality as heretofore, and the influence of youth and recent arrival in the country is fully recognised and dwelt upon. In some cases the occurrence of the disease was attributed and traced to insanitary conditions, in many others it was not, although want of success in that direction does not, of course, prove their absence. No material advance has been made with regard to the etiology or pathology of typhoid fever in India. The system of water filtration in barracks long ago gave rise to misgivings in our minds. There is only one safe way with water supply, and that is to be satisfied that its source is pure and that the water is not and cannot be contaminated from the time it leaves that source until it reaches the lips of the consumer. Large filter beds, properly designed and systematically used and superintended in connexion with waterworks at the main are one thing, but filtration in detail carried out and supervised by a multitude of human agents with all their liability to carelessness and error is quite another. In the same way it is easy enough to lay down excellent regulations on paper for a method of barrack-room filtration, but it is not easy to place implicit faith in their fulfilment in practice. However, we propose to omit all further reference to the etiology and pathology of enteric fever in India on the present occasion, as there will be an opportunity for considering it later on when dealing with the annual report of the Sanitary Commission with the Government of India for 1890, where these subjects are more fully entered upon. Cholera caused 50 admissions and 41 deaths in the Bengal command, being in the ratios of 1·2 and 1 per 1000 respectively.

The disease occurred in fourteen stations. The greatest number of cases in any station was 18 in Lucknow, where there were 13 deaths. Cholera was unusually prevalent in the district and city during the year. Lucknow appears to have been an increasingly unhealthy station of late. Single fatal cases of cholera occurred, as usual, at various stations during the year. More than half the cases and deaths took place in the third quarter and about a fourth in the last quarter of the year. This disease has a special interest at the present time, seeing that the epidemic now prevailing in Russia has followed the same route that it did in 1831-2 and on other occasions when it reached this country and America. The ratio of those constantly sick from venereal diseases in the Bengal command was 36.87 per 1000 during the year, which implies that as many as 1516.79 men, or rather more than a battalion and a half, were lost to the efficient strength of the army in Bengal from this cause. The constitutional form of the disease has, moreover, increased in prevalence, and this is particularly noticeable in comparing the ratio of admission for secondary syphilis in 1889 and 1890—52.3 and 60.2 per 1000—with the ratios in the previous three years, 1886-8—viz., 33.1, 27.2 and 30.8 per 1000 respectively. The reports of medical officers at several of the large stations allude, we are told, to this increased prevalence of constitutional disease.

Comparing the health of officers generally with that of the non-commissioned officers and men, it does not appear that the former enjoyed any advantage over the latter in this respect. The average strength of officers in the Bengal command was 1146, the number of attacks of illness 1123, the number of deaths 27, and there were 77 officers invalided to England. The ratio of sickness was, therefore, 979.9 per 1000, that of mortality 23.56, and that of invaliding 67.19 per 1000. Still, compared with last year, the mortality rate has declined by 3.72, those of sickness and invaliding having, however, increased; 65 officers were attacked with enteric fever, and 6 died. The death-rate among the women was 14.22, and that of the children 52.42 per 1000 during the year.

In the Madras command the death-rate among the British troops, 13.07, for 1890, was rather below that of the previous decennial average and 7.50 below that of the preceding year. It must be remembered, however, with regard to the decennial comparison that the year under report and the preceding year include the sickness and mortality among the troops in Upper Burma which previous years did not. There was only one case of cholera which terminated fatally during the year in the command. Enteric fever caused 126 admissions and 49 deaths, an admission-rate of 9.3 and a death-rate of 3.62 per 1000 for the year. Dysentery caused 558 admissions and 10 deaths, being in the ratios of 41.2 and 0.74 per 1000 respectively. In Bombay the loss to the command by death and invaliding was 490 men and the loss to the service by death and final discharge from the service as medically unfit was 368, being in the ratio of 28.84 per 1000 of strength, which is rather lower than the corresponding rate of the previous year. Cholera caused 7 admissions and 7 deaths. Enteric fever caused 131 admissions and 24 deaths, being at the rate of 10.3 and 1.88 per 1000 respectively. Dysentery gave rise to 252 admissions and 8 deaths, being in the ratios of 19.8 and 0.62 per 1000 respectively. The tables at pages 250, 259 and 268 give the relative prevalence of dysentery, diarrhoea, hepatitis and abscess of the liver in the several districts of the Bengal, Madras and Bombay commands respectively. It may be mentioned that influenza prevailed extensively in the Indian as in other commands during the year 1890.

The first paper in the Appendix to the Report is on the Progress of Hygiene during the year 1891, by Brigade-Surgeon-Lieutenant-Colonel J. Lane Nottter, M.A., M.D., Professor of Military Hygiene at the Army Medical School, Netley. After alluding to the work done at the various sections of the late International Congress of Hygiene and Demography, the subjects of sanitary legislation, literature, work of societies, special points of hygiene, foods, water analyses, alcoholic beverages and military hospitals in Berlin are all passed in review. The remarks on disinfection, considered under the heading of special points of hygiene, are worth reading. Steam heat is well known to be the most satisfactory and least injurious method of applying heat as a disinfectant. With regard to carbolic acid, attention is called to two points in order to obtain good results—viz., that the solutions should be sufficiently strong and that these take a considerable time to act. Any strength under 5 per cent. is unreliable and will not be effective within twenty-four hours.

All observers agree that mercuric chloride is the most active microbicide; a solution of 1 in 1000 destroyed anthrax spores within a few minutes. It is the only known disinfectant which, without any previous moistening or other preparation of the articles to be disinfected, destroys, says Koch, the most resistant organisms in a few minutes by a single application of a highly dilute solution. In the case of albuminous fluids, however, the sublimate may be precipitated and rendered ineffective or inert. Where it is desirable to use gaseous disinfectants chlorine is the best. As regards aerial disinfectants, although it may not be wise to discontinue their use altogether, they are nevertheless unreliable agents and their efficacy is often illusory. Any attempt to disinfect the air of sick-rooms by chemical means is useless, as if they are present in sufficient quantity they render the air of the room unbreathable. Nor should the fact that the contagia of different diseases possess different properties be overlooked. The poison of typhus becomes inert when diluted with air, and does not spread to any distance, whilst recent evidence goes to prove that small-pox is capable of transmission and does not lose its virulence by free dilution with air, but, retaining its power, can infect those living in the neighbourhood. The results of some experiments on "Morris's circulating filter" are given. The filter is favourably spoken of; the tests to which it was subjected were severe, and it is said to answer all the requirements necessary for a field-service filter. Professor Nottter concludes his paper with the notes he made while at Berlin in 1890 on the military hospitals and some of the barracks in that city.

The second paper is by Brigade-Surgeon-Lieutenant-Colonel C. H. Y. Godwin, Professor of Military Surgery at Netley. It gives a list of operations performed at the Royal Victoria Hospital during the year 1891, together with short abstracts of the most important cases. Several of these cases were interesting and instructive. The results obtained in the cases of empyema—in the second case particularly—were very good. The Assistant Professor of Military Medicine, Surgeon-Lieutenant-Colonel W. F. Stevenson, B.A., M.B., follows with a report from the medical division of the hospital, in which some interesting clinical facts are related in the abstracts of cases. Surgeon-Captain D. Bruce, the Assistant Professor of Pathology, contributes a paper on the Etiology of Malta fever, in which he details the steps he took to establish the presence of a definite micro-organism; he further deals with the morphology and the cultural characters of the micrococcus of this fever and the transmission of the disease to animals. A report of six cases of lightning-stroke at Aldershot by Surgeon-Captain J. E. Trask, and one on a case of recovery with useful limb after a compound fracture of the tibia and fibula into the knee-joint, with rupture of the internal saphenous vein and ligamentum patellae, by Surgeon-Captain J. F. S. Fowler, M.B., followed by the usual annual abstract of meteorological observations taken at Netley and foreign stations, conclude the volume.

## ROYAL COLLEGE OF PHYSICIANS.

At the quarterly comitia, held July 28th, 1892, the following report of the Censors' Board and the resolution appended thereto were adopted without a dissentient voice:—

"The President and Censors beg leave to report to the College as follows:—

"The Board has recently had under consideration, on reference from the Council, the case of a Member of the College whose name was proposed for the Fellowship in April last, and of whom it was then alleged that he had entered into an arrangement for the transfer of a practice from a Fellow of the College to himself for a pecuniary consideration.

"The correctness of the allegation has since been admitted by both the Fellow and Member concerned, but they have pleaded ignorance of any written or unwritten law or common understanding of the College against such a practice, and say that if such an understanding has existed in London it has never extended to the country.

"Under these circumstances the Censors' Board desires to call the attention of the Fellows to the transaction, which it regards as a contravention of the traditions and practice of the College, and one which should not be allowed to take place among Fellows or Members, whether residing in town or country.

"The Board thinks it further desirable that the College should express a clear opinion on the subject by way of obviating such transactions in future, and it therefore suggests for adoption by the College the following or some such resolution: 'That this College regards the sale and purchase of practices, or the transfer of patients from one physician to another for a pecuniary consideration, among Fellows or Members of its body, as contrary to the traditions and practice of the College, interfering with the freedom of patients and derogatory to the position of a physician.'

(Signed)

"July 11th, 1892"

"ANDREW CLARK, President.

'It was further resolved that the foregoing report and resolution be printed and that a copy be sent to every Fellow and Member of the College.

August 1st, 1892.

EDWARD LIVEING, Registrar.

## THE BRITISH ASSOCIATION OF SCIENCE IN EDINBURGH.

### THE PRESIDENT'S ADDRESS.

THE first general meeting of the members of the British Association of Science was held in Edinburgh in the Hall of the United Presbyterian Synod on Wednesday last. All departments of science were well represented. The retiring President, Dr. Huggins, was supported on the platform by Lord Kelvin, Lord McLaren, Sir D. MacLagan, Professor Roscoe, Professor Sir G. Stokes, Professor H. E. Armstrong, Sir F. Bramwell, Sir William Turner, Mr. Preece, Mr. Griffiths and Professor Bonny. The new President, Sir A. Geikie, who was cordially received, was briefly introduced by Dr. Huggins. He then delivered the presidential address, of which the following is a short outline:—

"Literature, philosophy, science," said the President, "have each in turn been guided by the influence of the great masters who have lived here, and whose renown is the brightest gem in the chaplet around the brow of this 'Queen of the North.' A hundred years ago a remarkable group of men was discussing here the great problem of the history of the earth. James Hutton, after many years of travel and reflection, had communicated to the Royal Society of this city, in the year 1785, the first outlines of his famous 'Theory of the Earth.' Nowhere was the profoundness of his insight more astonishing than in the clear, definite way in which he proclaimed and reiterated his doctrine, that every part of the surface of the continents, from mountain top to seashore, is continually undergoing decay, and is thus slowly travelling to the sea. He saw that no sooner will the sea floor be elevated into new land than it must necessarily become a prey to this universal and unceasing degradation. He perceived that, as the transport of disintegrated material is carried on chiefly by running water, rivers must slowly dig out for themselves the channels in which they flow, and thus that a system of valleys, radiating from the water-parting of a country, must necessarily result from the descent of the streams from the mountain crests to the sea. He discerned that this ceaseless and widespread decay would eventually lead to the entire demolition of the dry land, but he contended that from time to time this catastrophe is prevented by the operation of the underground forces, whereby new continents are upheaved from the bed of the ocean. And thus in his system a due proportion is maintained between land and water, and the condition of the earth as a habitable globe is preserved. Fortunately for his fame, as well as for the cause of science, his devoted friend and disciple Playfair at once set himself to draw up an exposition of Hutton's views. After five years of labour on this task there appeared the classic 'Illustrations of the Huttonian Theory,' a work which for luminous treatment and graceful diction stands still without a rival in English geological literature. Though professing merely to set forth his friend's doctrines, Playfair's treatise was in many respects an original contribution to science of the highest value. It placed for the first time in the clearest light the whole philosophy of Hutton regarding the history of the earth and enforced it with a wealth of reasoning and copiousness of illustration which obtained for it a wide appreciation. Then came the philosophy of Werner, who believed the rocks of the earth's crust to have been

chiefly chemical precipitates from a primeval universal ocean. The battle of these two contending schools raged fiercely here for some years, but the Wernerian doctrines were eventually abandoned even by Jameson himself. Again, Hutton had asserted that under the vast pressures which must be effective deep within the earth's crust chemical reactions must be powerfully influenced, and that under such conditions even limestone may conceivably be melted without losing its carbonic acid. In this he was followed by Sir James Hall, who succeeded in converting limestone under great pressure into a kind of marble and even fused it, and found that it then acted vigorously on other rocks. These admirable researches, which laid the foundations of experimental geology, constitute not the least memorable of the services rendered by the Huttonian school to the progress of science." Amongst the many other intensely interesting points alluded to by the President was the idea of boundless antiquity. "Playfair, re-echoing and expanding Hutton's language, had declared that neither among the records of the earth nor in the planetary motions can any trace be discovered of the beginning or of the end of the present order of things; that no symptom of infancy or of old age has been allowed to appear on the face of nature, nor any sign by which either the past or the future duration of the universe can be estimated; and that although the Creator may put an end, as He no doubt gave a beginning, to the present system, such a catastrophe will not be brought about by any of the laws now existing, and is not indicated by anything which we perceive. Lord Kelvin, in the writings to which I have already referred, first called attention to the fundamentally erroneous nature of these conceptions. He pointed out that from the high internal temperature of our globe, increasing inwards as it does, and from the rate of loss of its heat, a limit may be fixed to the planet's antiquity. He showed that so far from there being no sign of a beginning, and no prospect of an end to the present economy, every lineament of the solar system bears witness to a gradual dissipation of energy from some definite starting-point. He was inclined, when first dealing with the subject, to believe that from a review of all the evidence then available some such period as a hundred millions of years would embrace the whole geological history of the globe. Subsequently, however, and guided by physical inquiry, Lord Kelvin is willing, I believe, to grant us some twenty millions of years, but Professor Tait would have us content with less than ten millions."

The address from first to last was listened to with the deepest attention, and it was generally regarded as one of the most interesting discourses on geology ever delivered. At the conclusion of the address Lord Kelvin rose to move a vote of thanks. Lord Provost Russell seconded the motion, and the President's acknowledgment terminated the proceedings.

In the Section of Biology Professor M'Kendrick exhibited a newly devised apparatus for showing the curve traced by a contracting muscle and an apparatus for recording the time of voluntary movements. Professor G. Fritsch read a paper on the Origin of the Electric Nerves in the Torpedo, Gymnotus, Mormyrus and Malapterurus. Dr. Musgrove gave an exhibition on the screen of very finely injected retina of man and of the ox. The vegetable cells were considered by Dr. J. Clark.

In the department of Zoology Professor Lloyd-Morgan read a paper on the Method of Comparative Psychology, and the Rev. Dr. M'Cook of Philadelphia discussed the capability of spiders as weather prophets. He mentioned that this belief was as old as the time of Pliny, who stated that when a river was about to rise the spiders in the neighbourhood built their webs at a greater elevation, and that it seemed to have been almost universally believed. He concluded from his own observations that there was no ground for the theory. Professor Cossar Ewart exhibited the right fore foot of a horse with two complete hoofs and supporting fingers, as well as a splint-like remnant of the fourth metacarpal bone and a rudiment of the thumb with its corresponding carpal bone. This was interpreted as a reversion to the condition seen in three and four toed fossil horse-like animals. A paper on the Cause of Physiological Action at a Distance was contributed by Professor Errara of Brussels.

In the Section of Anthropology Dr. Clouston gave a long review of the progress made in criminal anthropology. Professor Struthers gave a description, illustrated by skeletons, of the articular processes of the vertebrae of the gorilla compared with those of man, and of the costo-vertebral variation in the gorilla. He exhibited two skeletons, and said he had

examined eighteen others. In the gorilla the chest was planted a vertebra lower than in man. The seventh vertebra presented all the characters of the normal sixth, the eighth all the characters of the seventh. In man he had seen the whole chest a vertebra too high. He had met with three cases of a rib more than usual. It was common enough in the human body. The cervical rib was more frequently met with than a supernumerary rib in the lumbar region. In the cases of three out of fourteen gorillas the extra rib was in the lower part of the chest. The gorilla had one more rib than man, but Professor Struthers had never met with the cervical rib in the gorilla in the upper part of the chest. The tendency in the human chest was to move upwards; the tendency in the gorilla's chest was to move downwards. The use of narcotics in the Nicobar islanders was explained by Mr. E. H. Man. Among many of the races of Trans-gangetic India and the Archipelago the habit was common of taking frequent quids of betel-nut and quicklime throughout the day. So firm a hold had this practice on both sexes that "betel quid-taking time" was a recognised expression, signifying an interval of some fifteen minutes' duration. Betel-chewing was commenced at the early age of ten or twelve, but instances were by no means rare of children who had acquired the habit before attaining six and even four years of age. Professor Macalister gave interesting descriptions of skulls from the Upper Congo, of the features of the brain of an aboriginal Australian, and the facial characters of ancient Egyptians as illustrated by skulls of undoubted antiquity.

## INTERNATIONAL CONGRESS OF EXPERIMENTAL PSYCHOLOGY.

[SECOND NOTICE.]

In our last issue we gave a brief account of the proceedings which took place at the meetings on the first two days of this Congress. On the third day, in Section A, several papers were read bearing upon psycho-physical questions, among them one by Dr. Verriest on the Physiological Basis of Rhythmic Speech, and one by M. Binet, who is peculiarly qualified to speak on such a subject, on the Psychology of Insects. In Section B, where hypnotism and kindred subjects formed the basis for discussion, Professor Delboeuf read a paper on the Appreciation of Time by Somnambulists. His observations were carried out on two subjects—youth, robust and healthy countrywomen, whose names frequently crop up in works on somnambulism. These subjects, he said, were incapable of reducing exactly into hours and minutes a number of minutes, such as 1000 or even 350, and still less of calculating at what hour the 1050th minute after, e.g., 6.35 p.m. would fall; but yet they received suggestions which they were to perform after 350, 900, 1600, 1150, 1300 and 3000 minutes! No conclusions were sought to be deduced from these results, but Professor Delboeuf said they were such as to merit attention and study. Other papers were read, one by Professor Hitzig on Attacks of Sleep and Hypnotic Suggestion, and one by Mr. F. W. H. Myers on the Experimental Induction of Hallucinations. Professor Janet discussed this paper at some length and mentioned some curious experiences. Thus one day a young female patient had an attack of somnambulism, during which she had written a letter which she had afterwards torn up and the contents of which she had forgotten. By causing her to gaze upon a shining surface he succeeded in making her read by hallucination the whole of the letter. Another patient, a young man, was in constant fear without knowing why. If he gazed on a shining surface for some time he would see the flames of a fire, and after listening for some time to a monotonous sound he would hear the sound of a fire-brigade bugle, and in this way was revealed the persistent idea which he had of a fire which he had witnessed some time previously. To explain such facts different causes were to be looked for in different cases. Professor Baldwin, in a paper on Suggestion and Will, endeavoured to find out the period in childhood at which will commences. He classified all responses of the infant in movement as preimitation, imitation and persistent imitation suggestions. In the first four weeks of life the infant's movements are largely organic and instinctive, but it then begins to respond to suggestions from others and from its environ-

ments. As soon as the child begins to see the inadequacy of its spontaneous imitations and to make efforts to improve them, will arises. He also argued that the loss of the mental functions in disease is by stages which form a series the reverse of that required for their acquisition. Some discussion, followed, and then the president read part of a report of the census of hallucinations which since the last meeting in 1889 has been actively carried on in England, and to some extent in the United States, France, Germany, Russia and Brazil. To the question "Have you ever, while in good health and believing yourself to be awake, seen a figure of a person or an inanimate object, or heard a voice which in your view was not referable to any external physical cause?" 17,000 answers were received in England. It appears that about one in ten of persons taken at random had experienced hallucinations of some kind, the apparitions being mostly those of living people or unrecognised human figures. A remarkable class was that of collective apparitions, the same hallucinations being simultaneously perceived by two or more different people, although in some of these instances there seemed to be a possibility of verbal suggestion from one to another. But after all deductions for possible sources of error there was a strong presumption against chance coincidence, if ordinary accuracy on the part of informants was to be assumed.

On the concluding day of the Congress Dr. Pilchener read a paper on Binocular Effects of Monocular Stimulation, and Dr. H. Donaldson gave in some detail his observations on the anatomy of the blind deaf-mute, Laura Dewey Bridgman. Dr. Berillon's paper on Les Applications de la Suggestion Hypnotique à l'Éducation, in which it was stated that cases of nervous insomnia, somnambulism, stammering, inveterate idleness &c. had been successfully treated by hypnotism, raised considerable discussion and some adverse criticism. Dr. Van Eeden considered that it was undesirable, for example, to paralyse a child's arm by suggestion and that moral suggestion alone should be employed, and Dr. Bernheim expressed the opinion that regular hypnotisation was not often needed in young children, the mother being able to inspire the needed suggestions at times of special susceptibility. Suggestion, he thought, had a rôle in correcting the perversions of moral sense, the result of bad companionship, but it could not create either an intelligence or a moral sense not born in a child. Dr. Berillon's reply was to the effect that the result of treatment alone would show whether the lack of moral sense in a child was due to original defect or to subsequent perversion.

Mrs. Sidgwick read a paper on Thought Transference. Numerous experiments had been made, and the successful percipients had been seven in number and were generally hypnotised. One percipient had succeeded in the experiments with numbers, when divided from the agent by a closed door and a distance of about seventeen feet, and the ideas had reached the percipient, as visual impressions recurred with closed eyes, or as hallucinations on a card or paper, and in other ways. Attention was drawn to the fact that only some persons are capable of acting as agents or percipients, and that there is variation in this peculiar ability in the same person on different days, and even at different times on the same day. Several other papers were read, among them one by Dr. Wallaschek on the Effect of Natural Selection on the Development of Music, and with a paper on a System of Psychological Interrogation, by M. Marillier, the scientific business of the Congress ended.

It was decided that the next congress should be at Munich in 1896, but a suggestion was made to hold a special meeting in America next year. When the usual votes of thanks had been passed, including one to the President and Council of University College for the use of the rooms, the Congress was formally dissolved.

## THE LOCUM TENENS.

THE question of a holiday to a general practitioner is so inseparably connected with that of securing a satisfactory locum tenens that in many cases the one may be said entirely to depend upon the other. Those who are in the habit of going away annually gain by experience a knowledge of the *modus operandi* and are in no need of advice from us. Those, on the other hand, who have only recently commenced practice, or who have had no experience of what leaving the care of

one's patients to a stranger implies, may be glad of some few hints on the subject. If the services of a personal friend can be obtained, so much the better; if not, resort must be had to advertisements, medical agents, or perhaps to some friend on the staff of the practitioner's old hospital. Answering advertisements implies some little delay, for of course references are necessary. Too much reliance must never be placed on these, for though testimonials may be given in perfect good faith they are generally written immediately the engagement is concluded and before any but the most serious causes of dissatisfaction have come to a principal's knowledge. Some agents request all principals to whom they have sent a locum tenens to fill up forms concerning him at the end of the year, and in this way they manage to purge their lists of unsatisfactory men, who, it is only fair to say, form but a small minority. The lowest terms generally offered to a locum tenens are three guineas a week, with, of course, board, lodging, and travelling expenses to and fro. The agent charges a small fee, generally 10s. 6d., to each party.

Supposing all arrangements made and the day fixed for going away, care should always be taken to secure a sufficiently long interview with the locum tenens to show him all the surgery and other arrangements, and to have a good talk with him over the cases under treatment or likely to be so. Of all these he should jot down notes unless the principal has already done so. Many memoranda are required which would not be found in the notes of a hospital clinical clerk—e.g., whether visits should be paid daily or otherwise and whether any particular period of the day is unsuitable. Care should be taken that every bottle in the surgery and store cupboard is properly and sufficiently labelled, and, if private formulæ are employed, that they should be easily accessible. If private abbreviations are used in the day-book, the locum tenens should be told what they mean; vaccination arrangements also must be explained to him. He should be shown where all the dressings, splints and instruments are, and told what neighbouring practitioners he should apply to for assistance, and what to do if drugs or dressings run short. The stable arrangements should be shown him, and it should be clearly settled whether he or the groom is to drive. The night bell, speaking-tube and slate for messages must be shown him, and, if possible, a map of the district left with him.

The confinement list will be worthy of a few minutes' conversation, and he must know how many after-visits are expected in a normal case. The scale of fees must be told him and he must understand whether he has authority to give receipts. It is often better to let the locum tenens send an acknowledgment of money received, with a promise that a formal receipt will be sent by the principal on his return. In case payments have to be made to the groom or surgery boy or for postage, some money should be left with the locum tenens. Where appointments are held the duties should be clearly explained, and he should be told how to distinguish between club and private patients who may call at the surgery, otherwise the day-book may be filled by the names of those who do not pay, while those of private patients are omitted. If possible, a definite date should be given for the principal's return, so that the locum tenens may take another engagement.

As to household arrangements, a locum tenens should be treated with consideration and his tastes should be as far as possible consulted. In conclusion, it may be said that though difficulties and unpleasantness do at times occur during the absence of a principal, the probability of anything taking place at all seriously damaging to a practice is exceedingly small if ordinary care be exercised in making the arrangements, and especially if the holiday be limited to three or four weeks.

#### DERBYSHIRE ROYAL NURSING INSTITUTION.—

The annual meeting of the Derbyshire Royal Nursing and Sanitary Institution was held on the 5th inst. at the St. James's Hall, Derby. The Mayor (Mr. T. H. Harrison) presided. The twenty-seventh report gave a satisfactory account of the working of the institution with regard to both its financial condition and the benefit conferred on the poor by means of the Society. Since 1865 (when the Association was established) 219 nurses had been supplied to the public. The services of Dr. Ogle as honorary secretary for twenty-seven years were duly acknowledged.

## Public Health and Poor Law.

### LOCAL GOVERNMENT DEPARTMENT.

#### REPORTS OF MEDICAL OFFICERS OF HEALTH.

*St. Luke's, Middlesex.*—In this metropolitan district the death-rate for 1891 reached as high as 30.1 per 1000. The corresponding rate for 1886-89 was only some 21 per 1000, and the great increase is found by Dr. Yarrow to be mainly due to bronchitis and pneumonia brought about by the influenza epidemic. The ordinary zymotic diseases were by no means exceptionally prevalent and it seems that special attention is given as regards those which are notified. It has been suggested in St. Luke's that erysipelas might be eliminated from the list of such diseases, and that measles should take its place. To the latter proposal Dr. Yarrow takes exception. He holds that it is practically of no use having notification without means of hospital isolation. We imagine that anything like hospital isolation of erysipelas does not exist; whilst, on the other hand, a number of medical officers of health have found that considerable advantage has accrued as the result of their being able to deal with the spread of measles through the agency of elementary schools, as they obtain thus early knowledge of its existence in individual households.

*Bollington Urban District.*—According to Mr. James Allen the death-rate of this district during 1891 was 15.6 per 1000 living. The unsatisfactory condition of the privies and midden-privies is maintained, but it is stated that a different method of scavenging has been inaugurated. Another defect lies in the reception of sewage into the bed of a stream which becomes dry, the result being an obvious nuisance.

#### VITAL STATISTICS.

##### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 5782 births and 3395 deaths were registered during the week ending Aug. 6th. The annual rate of mortality in these towns, which had declined in the preceding three weeks from 17.9 to 17.3 per 1000, was last week 17.4. In London the rate was 17.2 per 1000, while it averaged 17.5 in the thirty-two provincial towns. The lowest rates in these towns were 9.4 in Wolverhampton, 10.0 in Gateshead, 10.8 in Croydon and 10.9 in Burnley; the highest rates were 21.0 in Salford, 21.1 in Birkenhead, 21.4 Cardiff, 23.9 in Sunderland and 25.2 in Liverpool. The 3395 deaths included 623 which were referred to the principal zymotic diseases, against 625 and 585 in the preceding two weeks; of these, 300 resulted from diarrhoea, 126 from measles, 61 from scarlet fever, 57 from diphtheria, 54 from whooping-cough, 25 from "fever" (principally enteric) and not one from small-pox. These diseases caused the lowest death-rates in Halifax, Brighton, Croydon and Newcastle-upon-Tyne, and the highest rates in Liverpool, Sheffield, Sunderland, Birkenhead and West Ham. The greatest mortality from measles occurred in Bristol, Salford, West Ham, Oldham and Sunderland; from scarlet fever in Swansea and Plymouth; from whooping-cough in Preston, Burnley and Birkenhead; from "fever" in Sunderland and from diarrhoea in Derby, Bolton, Sheffield, Portsmouth, Leicester, West Ham, Liverpool and Cardiff. The 57 deaths from diphtheria included 42 in London, 3 in Birmingham and 2 each in West Ham, Preston and Sheffield. No death from small-pox was registered either in London or in any of the thirty-two provincial towns; 7 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 4 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2995, against numbers increasing from 1226 to 2864 on the preceding nineteen Saturdays; 346 new cases were admitted during the week, against 382 in each of the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 185 to 155 in the preceding five weeks, further fell to 143 last week and were 47 below the corrected average. The causes

of 69, or 2.0 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Bolton, Newcastle-upon-Tyne and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Brighton, Birmingham, Leicester and Bradford.

#### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 18.4 and 17.5 per 1000 in the preceding two weeks, rose again to 18.5 during the week ending Aug. 6th, and exceeded by 1.1 per 1000 the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14.0 in Greenock and 16.3 in Edinburgh to 18.9 in Perth and 19.9 in Glasgow. The 514 deaths in these towns included 31 which were referred to diarrhoea, 23 to measles, 11 to whooping-cough, 8 to scarlet fever, 7 to diphtheria, 3 to "fever" and not one to small-pox. In all, 83 deaths resulted from these principal zymotic diseases, against 66 and 54 in the preceding two weeks. These 83 deaths were equal to an annual rate of 3.0 per 1000, which was slightly below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhoea, which had been 10 in each of the preceding two weeks, rose to 31 last week, of which 16 occurred in Glasgow and 5 in Dundee. The deaths referred to measles, which had been 28 and 19 in the previous two weeks, rose again last week to 23, and included 16 in Glasgow, 4 in Edinburgh, and 3 in Aberdeen. The 11 fatal cases of whooping-cough were within 3 of the number in the preceding week and included 7 in Glasgow. The deaths from scarlet fever, which had declined from 6 to 3 in the previous three weeks, increased to 8 last week, of which 5 occurred in Glasgow and 2 in Edinburgh. The 7 fatal cases of diphtheria exceeded those recorded in recent weeks, and included 3 in Glasgow and 2 in Leith. The deaths referred to diseases of the respiratory organs in these towns, which had been 59 and 114 in the preceding two weeks, declined last week to 77, but exceeded by 17 the number in the corresponding week of last year. The causes of 49, or nearly 10 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 19.8 and 28.3 per 1000 in the preceding two weeks, declined to 21.5 during the week ending Aug. 6th. During the first five weeks of the current quarter the death-rate in the city averaged 23.1 per 1000, against 18.0 in London and 16.3 in Edinburgh. The 144 deaths in Dublin during the week under notice showed a decline of 46 from the number in the preceding week, and included 6 which were referred to measles, 5 to diarrhoea, 2 to whooping-cough and not one either to small-pox, scarlet fever, diphtheria or "fever." In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.9 per 1000, the zymotic death-rate during the same period being 3.5 in London and 1.8 in Edinburgh. The fatal cases of measles, which had been 7 and 8 in the preceding two weeks, declined to 6 last week. The deaths referred to diarrhoea, which had been 4 and 3 in the previous two weeks, rose again to 5 last week. The 144 deaths registered last week in Dublin included 26 of infants under one year of age and 26 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from those recorded in the preceding week. Seven inquest cases and 5 deaths from violence were registered; and 46, or nearly one-third, of the deaths occurred in public institutions. The causes of 9, or more than 6 per cent., of the deaths in the city last week were not certified.

#### VITAL STATISTICS OF LONDON DURING JULY, 1892.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during the month of July in each of the forty-one sanitary districts of London. With regard to the notified cases of infectious disease in London during last month, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the accompanying table was equal to 12.2 per 1000 of the population, estimated at 4,263,294

persons in the middle of this year. Owing to the increasing prevalence of scarlet fever in the metropolis this rate shows a further increase upon those recorded in the preceding five months, which had steadily risen from 5.1 to 9.9 per 1000. Among the various sanitary districts the rates last month were considerably below the average in Paddington, Fulham, St. James (Westminster), Hampstead, Clerkenwell, St. Luke and Lewisham; while they showed the largest excess in Westminster, City of London, Bethnal-green, Whitechapel, Limehouse, Mile-end Old Town, Poplar and Plumstead. The prevalence of small-pox in London showed a further marked decline during July, an average of only 5 cases weekly being notified, against 27 in May and 16 in June; of the 18 cases notified during last month 8 belonged to Plumstead and 2 to St. Giles sanitary districts. The Metropolitan Asylum Hospitals and the Highgate Small-pox Hospital contained 9 small-pox patients at the end of July, against 108 and 40 at the end of the preceding two months; the weekly admissions averaged 5, against 29 and 11 during May and June. The prevalence of scarlet fever during July showed a considerable further increase upon that recorded in recent months. This disease was proportionally most prevalent in St. George (Hanover-square), Holborn, City of London, Whitechapel, Limehouse, Mile-end Old Town, Poplar, Newington and Plumstead sanitary districts. The Metropolitan Asylum Hospitals contained 2763 scarlet fever patients at the end of July, against numbers increasing from 1142 to 2117 at the end of the preceding five months; the weekly admissions averaged 335, against 170, 200 and 238 in the previous three months. Diphtheria showed the highest proportional prevalence during July in Hammersmith, Chelsea, Westminster, Hampstead, City of London, Bethnal Green and Whitechapel. There were 283 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of July, against numbers increasing from 198 to 255 at the end of the preceding five months; the weekly admissions averaged 56, against 33, 41 and 49 in the previous three months. Among the various sanitary districts enteric fever was proportionally most prevalent in Hackney, Bethnal Green, Poplar, Newington and Rotherhithe. The Metropolitan Asylum Hospitals contained 77 enteric fever patients at the end of July, against 47 and 57 at the end of the preceding two months; the weekly admissions averaged 16, against 8 and 10 in the preceding two months. Erysipelas showed the highest proportional prevalence during July in Westminster, Marylebone, St. Giles, City of London, Bethnal Green and Battersea.

The mortality statistics in the accompanying table relate to the deaths of persons actually belonging to the various metropolitan sanitary districts, the deaths occurring in the institutions of London having been distributed among the various sanitary districts in which the patients had previously resided. The distribution of these deaths, and especially of those resulting from zymotic diseases, affords the most trustworthy data that can be secured upon which to calculate reliable rates of mortality. During the four weeks ending Saturday, July 2nd, the deaths of 5837 persons belonging to London were registered, equal to an annual rate of 17.8 per 1000, against rates declining from 24.2 to 16.9 in the preceding five months. The lowest death-rates during July in the various sanitary districts were 9.8 in Hampstead, 11.3 in Lewisham, 11.9 in St. George (Hanover-square), 12.4 in Plumstead, 12.5 in Wandsworth and 14.5 in Kensington and in Woolwich; in the other sanitary districts the rates ranged upwards to 23.8 in Newington, 24.0 in Whitechapel, 24.1 in Rotherhithe, 27.9 in St. George-in-the-East, 28.4 in St. Luke and 29.6 in St. Olave (Southwark). During the four weeks of July 1277 deaths were referred to the principal zymotic diseases in London; of these, 627 resulted from diarrhoea, 300 from measles, 129 from diphtheria, 100 from whooping-cough, 88 from scarlet fever, 29 from "fever" (including 25 from enteric fever, 2 from typhus and 2 from simple fever) and 4 from small-pox. These 1277 deaths were equal to an annual rate of 3.9 per 1000, against 3.3 and 3.1 in the preceding two months. Among the various sanitary districts the lowest zymotic death-rates were recorded in St. James (Westminster), Hampstead, City of London, St. Saviour (Southwark), Lewisham and Woolwich; and the highest rates in Westminster, Holborn, St. Luke, Mile-end Old Town, St. George (Southwark) and St. Olave (Southwark). Four fatal cases of small-pox belonging to London were registered during July, of which 2 belonged to Plumstead, 1 to Mile-end Old Town, and 1 to Battersea. The 300 deaths referred to measles exceeded by 81 the corrected average number in

MONTHLY ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON.—JULY, 1892.  
(Specially compiled for THE LANCET.)

Sanitary areas.	Estimated population in the middle of 1892.	NOTIFIED CASES OF INFECTIOUS DISEASE.										DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.										Deaths of infants under one year to 1000 births.

the corresponding month of the preceding ten years; among the various sanitary districts this disease showed the highest proportional fatality in Hammersmith, Holborn, Bethnal Green, Limehouse, St. George (Southwark) and Camberwell. The 88 fatal cases of scarlet fever were only 7 above the average; it is remarkable that the mortality from this disease shows so small an excess, considering its epidemic prevalence at the present time; among the various sanitary districts scarlet fever was proportionately most fatal in Chelsea, Whitechapel and Plumstead. The 129 deaths referred to diphtheria exceeded by 52 the corrected average; this disease showed the highest proportional fatality in Westminster, St. Giles, City of London, Bethnal Green and Whitechapel. The 100 fatal cases of whooping-cough were less than half the average number; this disease was not prevalent last month in any of the sanitary districts. The 29 deaths referred to different forms of fever were 23 below the corrected average; the mortality from this disease showed no marked excess in any of the sanitary districts. The 627 fatal cases of diarrhoea were as many as 298 below the average; this disease was proportionately most fatal in Fulham, St. Giles, Holborn, St. Luke, Newington and Greenwich. In conclusion, it may be stated that the mortality in London during July from these principal zymotic diseases in the aggregate was as much as 20 per cent. below the average, owing principally to the fact that the fatality of summer diarrhoea was unusually low.

Infant mortality in London, measured by the proportion of deaths under one year of age to registered births, was equal to 182 per 1000 during July; the lowest rates of infant mortality were recorded in St. George (Hanover-square), Hampstead, Islington, St. Martin-in-the-Fields, Woolwich and Plumstead; the highest rates in Kensington, Chelsea, Holborn, St. Luke, Newington and Rotherhithe.

## THE SERVICES.

### THE MOVEMENTS OF THE ARMY AND THE HEALTH OF TROOPS ON SHIPBOARD.

SOME idea may be obtained of the movements of the British army from the following returns for the year 1890. The troops proceeding on service abroad numbered 18,786, and those returning from abroad 12,206. The troops proceeding from one station abroad to another were 6772. The invalids returning to England numbered 2118, of whom 22 died on the voyage home. The sanitary condition of the different vessels and troopships, and the accommodation provided for the troops on the various voyages, were generally reported to be satisfactory.

#### SOME OF OUR INDIAN HILL STATIONS.

According to the latest official reports Darjeeling seems to maintain its reputation as a sanatorium for troops whose health has suffered in Calcutta, the Presidency District and the plains of India. The great majority sent up recovered after a few months' residence. The general sanitation of the cantonment—so difficult to maintain in the case of many of our hill stations—was well looked after. Gnathong, situated at an elevation of 12,030 feet above the sea level, on the eastern frontier of Sikkim, is reported to be a healthy station, notwithstanding the great rainfall during the summer months and the great cold in winter. The troops live in wooden huts, situated inside a stockade built on the slope of a hill, and arranged in terraces. The water-supply is from a spring on the hillside a few hundred yards distant from the fort and is excellent. The great cold during the winter necessitates the ample supply of blankets and warm clothing. There should be material at this station for some interesting observations for a medico-topographical report.

#### MOVEMENTS OF THE MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel MacAdam has been struck off the strength of the Southern District prior to retirement. Surgeon-Captain Dixon has joined the North-western District for duty. Surgeon-Captain Birrell has rejoined at Hamilton from temporary duty at Piershill. Surgeon-Captain Woodhouse has obtained leave from Woolwich. Surgeon-Major Lauprey has joined the Home District for duty after a tour of service in West Africa on colonial service. Surgeon-Captain Will has taken up duty at Oxford. Surgeon-Lieutenant-Colonel Gabbett and Surgeon-Captain Farmer-Bringhurst have obtained sick leave from Madras. Surgeon-

Captain Clarkson has reported himself for duty at Dover. Surgeon-Captain Nicolls has joined at Omagh. Surgeon-Captain Cotterell has arrived at Gibraltar on return from leave. Surgeon-Captain Baird has proceeded on leave prior to embarkation on foreign service. Brigade-Surgeon O'Brien has obtained leave from Christchurch. Surgeon-Lieutenant-Colonel Dwyer has reported his arrival in Dublin for duty.

#### PROFESSORSHIP OF MILITARY SURGERY.

The Professorship of Military Surgery at the Army Medical School, Netley, vacant by the resignation of Surgeon-Colonel Godwin, has, we understand, been conferred upon Surgeon-Lieutenant-Colonel W. F. Stevenson, Assistant Professor of Clinical and Military Medicine.

#### GOOD SERVICE PENSION.

We learn that the good service pension of £100 a year, which has fallen in by the death of Surgeon-General Hassard, retired pay, has been bestowed upon Surgeon-Major-General J. B. C. Reade, C.B. This officer served throughout the Crimean campaign, including the battle of Alma, sortie of Oct. 26th, battle of Inkerman, assaults on the Redan of June 18th and Sept. 8th, and siege of Sebastopol. He was wounded and has medal with three clasps and Turkish medal. He served in the Indian Mutiny, including the action of Cawnpore, siege and capture of Lucknow, attack of Fort Rooyab, action of Allgunge, battle of Newsbyunge, passage of the Goomtee, &c., and the Oude campaign, and received the medal with clasp.

#### INDIAN MEDICAL SERVICE.

Surgeon-Captain Bird, now at Kohima, has been appointed to succeed Surgeon-Major Owen as Surgeon to the Commander-in-Chief. Surgeon J. Battersby, Medical Staff, has been selected as Cantonment Surgeon for the station of Rawul Pindi. The new hospital system introduced by Lord Roberts for the care and treatment of all followers and nations living within cantonment limits supplies a want long felt, and is already being attended with marked success.

*Government of India.*—Surgeon-Captain J. A. Burton, Madras Establishment, is appointed to officiate as Civil Surgeon, Amraoti, vice Surgeon-Captain R. B. Roe, on leave. Surgeons-Captain T. Grainger, M.D., and J. G. Jordan, M.B., C.M., Bengal Establishment, are placed temporarily at the disposal of the Bengal Government. Brigade-Surgeon-Lieutenant-Colonel L. D. Spencer, M.D., I.M.S. (Bengal), Residency Surgeon and Chief Medical Officer, Rajputana, is replaced at the disposal of the Military Department. Surgeon-Captain W. G. Thorold, Bengal Establishment, is replaced at the disposal of the Government of the North-West Provinces and Oudh from May 31st. Surgeons-Captain W. Vost, M.B., and H. W. Elphick, Bengal Establishment, are placed temporarily at the disposal of the Government of the North-West Provinces and Oudh. Surgeon-Captain E. Hudson, Bengal Establishment, is placed temporarily at the disposal of the Chief Commissioner, Burmah. Surgeon-Lieutenant-Colonel J. H. Newman, M.D., I.M.S. (Bengal), Civil Surgeon, Ajmere, and Medical Officer of Merwara Battalion, is appointed Residency Surgeon and Chief Medical Officer, Rajputana, vice Brigade-Surgeon-Lieutenant-Colonel L. D. Spencer, M.D. Surgeons-Captain C. E. Sunder, M.B., A. H. Nott, M.B., and J. T. Calvert, M.B., Bengal Establishment, are placed temporarily at the disposal of the Bengal Government.

It is notified that, on the recommendation of the Government of India, Her Majesty's Government has been pleased to confer a good service pension on Surgeon-Colonel Archibald Hamilton Hilson, M.D., I.M.S.

*Bengal Government.*—Surgeon-Captain F. A. Rogers is appointed to officiate as Civil Surgeon of Darbhanga, vice Surgeon-Major R. R. H. Whitwell. Surgeons-Captain T. Grainger, M.D., and J. G. Jordan, M.B., C.M., Bengal Establishment, are placed temporarily at the disposal of the Government of Bengal. Mr. W. Forsyth, Officiating Health Officer, Port Calcutta, is confirmed in that appointment from the date on which Dr. R. McLeod assumed permanent charge of the office of Superintendent of Emigration and Protector of Emigrants, Calcutta. Surgeon-Major R. R. H. Whitwell, Officiating Civil Surgeon of Monghyr, is appointed to officiate as Civil Surgeon of Muzaffapur, vice Surgeon-Captain E. S. Peck, on furlough. Dr. C. Banks is appointed to officiate as Civil Medical Officer of Monghyr. Surgeon-Captain T. Grainger is appointed to officiate as Civil Surgeon, Champaran, vice Surgeon-Major E. Bovill. Surgeon-Captain J. G. Jordan acts as Civil Surgeon, Jessore.

**Punjab Government.**—Surgeon M. A. Ker assumed charge of Jhelum district on May 10th, vice Surgeon-Major K. M. Downie. Surgeon-Major W. A. Mawson, 11th Bengal Lancers, is appointed Civil Surgeon, Rawul Pindi, vice Brigade Surgeon-Lieutenant-Colonel Ross, on leave. Surgeon-Captain J. A. Cunningham, Civil Surgeon, from Mooltan to Lahore, as Civil Surgeon, Superintendent of Lunatic Asylum, Professor of Midwifery and Forensic Medicine, in the Lahore Medical College and Medical Officer in Charge, Government College, Lahore, on May 6th, relieving Surgeon-Colonel W. Center. Surgeon-Major S. Little, Civil Surgeon, from Ferozepore to Mooltan from May 16th. Surgeon-Lieutenant-Colonel G. Davis assumed charge of the Civil duties of Hazara district on June 2nd, relieving Surgeon-Major J. A. Nelis.

**Madras Government.**—Surgeon-Captain R. Robertson acts as Civil Surgeon at Guntur. Surgeon-Major H. Allison, M.D., Fort Surgeon, Madras, also acts as Chemical Examiner. Surgeon-Major S. C. Sarkies acts as District Surgeon, Nollore. Surgeon-Major G. L. Walker, M.D., acts as District Surgeon, Malabar. Surgeon-Major W. F. Thomas acts as District Surgeon, Chingleput. Surgeon-Major W. H. Browning is appointed *pro tem.* Surgeon to his Excellency the Governor.

**Bombay Government.**—Surgeon-Captain T. E. Dyson, M.B., I.M.S., is placed permanently at the disposal of the Government for the Civil Department. Surgeon-Captain T. D. C. Barry, I.M.S., is placed at the disposal of the Government permanently in the Civil Department. Surgeon-Captain John Crimmin, V.C., and Surgeon-Major F. F. MacCartie, M.B., delivered over and received charge of the office of Health Officer of the Port of Bombay on May 17th. Surgeon-Captain S. E. Prall, M.B., B.S., acts as Civil Surgeon, Sukur, vice Surgeon-Captain W. A. Corkery. Surgeon-Captain T. D. C. Barry to be Professor of Chemistry and Medical Jurisprudence, Grant Medical College and Elphinstone College, vice Brigade-Surgeon-Lieutenant-Colonel I. B. Lyon, C.I.E., retired. Dr. D. MacDonald, B.Sc., C.M., to be substantive *pro tem.*; also Lecturer in Experimental Physics, Elphinstone College, vice Mr. N. A. Moos.

**Central Provinces.**—Surgeon-Colonel J. G. Pilcher and Brigade-Surgeon-Lieutenant-Colonel W. Center, M.B., made over and assumed charge of the office of Deputy-Surgeon-General and Sanitary Commissioner, Central Provinces, on May 11th. Brigade-Surgeon-Lieutenant-Colonel Peter Cullen, M.D., Civil Surgeon, Narsinghpur, Central Provinces, retires from June 1st.

**North-West Provinces and Oudh Government.**—Surgeon-Major P. J. Kreyer, Civil Surgeon, Moradabad, to hold Visiting Charge of Bijnor district, vice Surgeon-Captain G. H. Fink. Surgeon-Major J. Sykes, Civil Surgeon, Saharanpur, to the Visiting Charge of Muzaffarnagar district, vice Surgeon-Major E. Mulvany, on leave. Assistant-Surgeon E. H. Thomas, M.B., from Prince of Wales's Hospital, Benares, to Najina Hospital, Bijnor district.

**Burma Government.**—Surgeon-Major W. G. King, I.M.S., is posted to the Officiating Charge of the 25th Regiment M.I., vice Surgeon-Captain C. Donovan, relieved. Surgeon-Captain S. A. C. Dallas, I.M.S., in charge of Shore Hospital, Mandalay, to proceed to Rangoon and report himself to the Administrative Medical Officer, Rangoon district, and Surgeon-Captain C. H. Leet-Palk, I.M.S., to assume charge of Shore Hospital, Mandalay. Surgeon-Captain E. O. Weight, M.S., is attached to Station Hospital, Mandalay, for duty.

**General Orders.**—2nd Sikh Infantry: Surgeon-Captain E. Wilkinson to Officiating Charge of Regiment, vice Surgeon-Captain J. W. Rodgers.—2nd Battalion, 5th Gurkha Rifles: Surgeon-Captain W. Henvey to Officiating Charge of Battalion, vice Surgeon-Captain G. Duncan.—24th Punjab Infantry: Surgeon-Captain H. F. Whitechurch, from Officiating to Charge of Regiment, vice Surgeon-Lieutenant-Colonel H. J. Linton.—26th Punjab Infantry: Surgeon-Captain J. K. Close, from Officiating Charge of 21st Punjab Infantry, to Charge of Regiment, vice Brigade-Surgeon-Lieutenant-Colonel J. M. Fleming.—4th Bengal Cavalry: Surgeon-Captain W. W. White, from Officiating to Charge of Regiment, vice Surgeon-Lieutenant-Colonel C. W. Calthrop.—2nd Bengal Lancers: Surgeon-Captain F. Okineally to Officiating Charge of Regiment, vice Surgeon-Captain A. W. Dawson.—15th Bengal Lancers: Surgeon-Captain A. G. Hendley, to Officiating Charge of Regiment, vice Surgeon-Captain E. Hudson.—2nd Bengal Light Infantry: Surgeon-Captain B. C. Oldham, to Officiating

Charge of Regiment, vice Surgeon-Captain W. J. Buchanan.—13th Bengal Infantry: Surgeon-Captain B. H. Deare to Officiating Charge of Regiment, vice Surgeon-Captain F. P. Maynard.—31st Punjab Infantry: Surgeon-Captain J. S. S. Lumsden, to Officiating Charge of Regiment, vice Surgeon-Captain J. G. Jordan.—52nd Pioneers: Surgeon-Captain S. B. Smith, to Officiating Charge of Regiment, vice Surgeon-Captain T. Grainger.—40th Pathan Regiment: Surgeon-Captain H. R. C. Barber, to Officiating Charge of Regiment, vice Surgeon-Captain W. Vost.—42nd Gurkha Rifles: Surgeon-Captain R. Bird, to Officiating Charge of Regiment, vice Surgeon-Captain F. A. Rogers.

**Assam Government.**—Surgeon-Captain R. Bird, M.D., Officiating Medical Officer, 42nd Gurkha Rifles, appointed to Charge of Civil duties of Naga Hills district, from date of taking charge from Surgeon-Captain F. A. Rogers, D.S.O.

**Bombay Medical Establishment.**—Surgeon-Lieutenant-Colonel James Davidson to be Brigade-Surgeon-Lieutenant-Colonel (dated April 2nd, 1892).

The Queen has approved of the transfer of the under-mentioned Officer to the Half-Pay List:—Surgeon-Captain Wm. Wilfrid Webb, Bengal Medical Establishment (dated Aug. 22nd, 1892).

Surgeon-Captain W. H. Quicke and Surgeon-Major James S. Wilkins respectively delivered charge of the Kira District Gaol on July 14th, 1892.

The services of Surgeon-Captain G. J. H. Bell, Bengal Medical Establishment, are placed at the disposal of the Chief Commissioner of Burmah.

Surgeon-Captain C. Donovan, M.D., to do duty, Madras district. Surgeon-Captain S. A. C. Dallas, to do duty, Madras district.

Surgeon-Lieutenant R. H. Elliot, on arrival from England, to do duty, Secunderabad district.

Surgeon-Major E. Mair, Officiating Inspector-General of Prisons, N.W. Provinces and Oudh, on being relieved of the duties of that office, is appointed to revert to his substantive appointment as Superintendent, Central Prison, Bareilly.

Surgeon-Captain C. MacTaggart, Honorary Surgeon, Ghazipur Light Horse, to be Honorary Surgeon of the Agra Volunteer Rifle Corps.

#### ARMY MEDICAL STAFF.

Surgeon-Major W. Barrett, M.B., Retired List, Army Medical Staff, died at 8, Merchiston-place, Edinburgh, on the 1st inst., aged seventy-six years. He joined the army Oct. 20th, 1843; became surgeon March 24th, 1854; surgeon-major Dec. 16th, 1864; and retired June 20th, 1865.

**NAVAL MEDICAL SERVICE.**—Surgeon Eric E. Hershaw, to the *Nelson*.

**VOLUNTEER CORPS.**—*Artillery*: 1st Forfarshire: Surgeon-Lieutenant D. Laing, M.D., is appointed Lieutenant (dated Aug. 6th, 1892).

## Correspondence.

"Audi alteram partem."

### THE PATHOLOGY AND TREATMENT OF CHOLERA.

To the Editors of THE LANCET.

SIRS,—Epidemic cholera is now causing great mortality in various parts of Europe and may not unlikely invade our own country. The subject naturally excites much general interest. The time therefore seems favourable for directing the attention of the profession to certain disputed points regarding the nature and treatment of the disease. In *The Times* of Aug. 5th, 1892, the Vienna correspondent of that paper states that Professors Nothnagel and Kahler, acting under instructions from the Minister of Education, have issued a circular advising people of the precautions they should adopt in case of an outbreak of cholera. They accept Koch's comma bacillus as the cause of cholera, and amongst some directions which would be generally accepted without controversy there is one which I deem to be in the highest degree unwise and dangerous—viz., that "cases of choleric" (that is, choleraic diarrhoea)

"are to be treated immediately with opium preparations, red wine, cognac, or rum-arrack in boiled water." They also declare that "the immediate cause of death in cholera is asphyxiation, consequent upon the thickening of the blood." On the contrary, I maintain—and I have completely proved—that the blood thickening in cholera is not the cause, but a consequence of the asphyxiation, which results from the greatly impeded pulmonary circulation.

Mr. C. N. Macnamara, in his recently published small treatise on "Asiatic Cholera: its History, Causes, and Treatment," says on page 59: "With reference to the poison which we believe the cholera bacillus produces, several theories have been advanced to explain its action in connexion with the pathological changes found after death. Among these theories, that advocated by Sir George Johnson takes a prominent position, and by many pathologists is held to be best capable of accounting for the symptoms and the changes found after death from cholera." He then gives a brief, but, so far as it goes, a clear and correct statement of my explanation of choleraic collapse. But it appears from a subsequent paragraph that he still believes that what he calls "dehydration of the blood and tissues" is the most important factor in the pathology of cholera. And this theory of dehydration, unfortunately as I think, is his main guide in the treatment of the disease. He says, under the head of "Treatment," p. 63: "In the early stages of Asiatic cholera we may frequently stay the further progress of the disease by opium combined with acetate of lead or with dilute sulphuric acid. Twenty drops of laudanum with three grains of acetate of lead, or twenty minims of diluted sulphuric acid, should be given and repeated every hour for three doses (in the case of adult patients) if the purging continues."

If Mr. Macnamara, before publishing this last treatise on cholera, had read the chapter on cholera in my "Medical Lectures and Essays," which, in a recent conversation with me, he admitted that he had not done, he would have seen that I have adduced abundant evidence to prove that the repressive treatment of choleraic diarrhoea by opium, so far from staying the further progress of the disease, often tends to prolong the diarrhoea and frequently leads on to collapse. Mr. Macnamara, at p. 42, quotes the well-known and most instructive experiments by Dr. Koch for the production of cholera in guinea-pigs.<sup>1</sup> Dr. Koch found that he failed to produce cholera in these animals by introducing the cholera bacteria into the stomach unless at the same time he injected into the peritoneal cavity a narcotic dose of tincture of opium, his object being "to render it possible for the comma bacillus to remain longer and gain a footing in the intestine." In this manner he induced fatal cholera in thirty out of thirty-five guinea-pigs experimented upon. Koch's experiments have been repeated by Dr. Neil Macleod,<sup>2</sup> who killed thirty-eight out of fifty-four guinea-pigs by the injection of cholera bacilli into the stomach, and opium injections into the peritoneum to check peristalsis and so allow time for the multiplication of the organisms. Now it appears to me passing strange that Mr. Macnamara and those who agree with him in advocating the repressive opium treatment of choleraic diarrhoea fail to see that in adopting this practice they are imitating on the human subject the fatal experiments which Koch and others have performed upon guinea-pigs.

In the chapter on cholera to which I have referred I have reported numerous cases in my own practice and in that of others in which the abrupt arrest of the discharges by opium has been followed by fatal collapse; while in no single instance, out of a very large number treated in the early stage by evacuants, has the disease passed on to the stage of collapse.

Mr. Macnamara mentions the fact of his having himself gone through a severe attack of cholera. This occurred when he was assisting me in the cholera wards of King's College Hospital in 1854; and, as his life was probably saved by the evacuant treatment which he then adopted, I here reproduce *verbatim* the notes of his case with which he furnished me soon after his recovery:—"On Monday night, at about eleven o'clock I awoke with violent pain and spasm in my stomach and a most distressing state of oppression, with an inclination to vomit. These symptoms were quickly followed by cramps in my hands and feet. I, at once got up and took an emetic, and as soon as the

vomiting which it excited had ceased I took an ounce of castor oil. In about half an hour's time I was violently purged, and so much relief did I experience from it that I repeated the dose of castor oil during the following hour. From this time until eight o'clock in the morning I was purged, and vomited so frequently that I became quite exhausted; yet I suffered little pain, and had lost that dreadful sense of oppression to which I before alluded. I had then two hours' sleep and awoke much refreshed. Throughout the day my bowels were opened several times, and I vomited once or twice after taking food; but in the evening I went down to Blackheath, passed a most comfortable night there, and the next day returned to town ready to resume my duties, although much pulled down by my severe though short illness.—C. N. M., M.R.C.S., King's College Hospital, September, 1854."

The dreadful sense of oppression which he describes was probably due to the commencing embarrassment of the pulmonary circulation by the action of the cholera poison. From this he was speedily relieved by his prompt recourse to evacuant treatment. If instead of the emetic and castor-oil, of which, however, he took at least twice as much as was necessary, he had taken repressive doses of opium, the result might have been very different.

In the earlier period of my professional career I made great sacrifices by persistently advocating a theory and treatment of cholera which the profession generally looked upon as erroneous. At the present time I have nothing either to gain or to lose by discussing the subject, but so long as I can wield my pen I deem it a public duty to protest against theories which have been proved to be false and methods of practice which ample experience has shown to be injurious.

I am, Sirs, yours faithfully,

Saville-row, Aug. 8th, 1892.

GEORGE JOHNSON.

## A CASE OF DEATH UNDER CHLOROFORM.

To the Editors of THE LANCET.

SIRS.—A fatal result from the administration of chloroform recently occurred at the Royal Victoria Hospital, Netley. The patient, a man aged twenty-one, had been in hospital over twelve months with tubercular disease of the hip-joint, and was in consequence completely broken down in health. Excision of the head of the femur had been performed in November, 1891; the disease, however, progressed in the acetabulum and the patient was being gradually worn out with the chronic discharge and hectic fever from a large pelvic abscess which had formed. The operation in prospect was to give an outlet to this abscess. The heart was carefully examined beforehand and nothing was found to contraindicate the use of the anæsthetic. The lungs had also been examined, but no evidence of organic disease was present. Krohne's Hyderabad safety inhaler was used for the administration, into which half a drachm of chloroform was placed. For the first few respirations the patient, who was in a highly excitable state, breathed well and took the anæsthetic quietly without struggling, but suddenly, without warning, he became extremely pallid, the pupils widely dilated and, with the exception of a few short gasping breaths, respiration entirely ceased. The heart's action continued very feebly for some few seconds after. On the first indication of danger the inhaler was immediately removed, the tongue drawn forward, the chin kept elevated, the head lowered and artificial respiration commenced and continued for about half an hour. Electricity was at once applied to the phrenic nerve and over the region of the heart and half a drachm of ether injected subcutaneously, but all with no avail, the patient showing no further sign of life. No operative procedure had been started, as barely one or two minutes had elapsed from the commencement of the inhalation until death occurred.

An examination was made forty-eight hours after death. The heart was normal in size, its walls pale and thinner than natural; there was no valvular disease and no coagula were present in either of the ventricles. The lungs were found to be somewhat congested, but there were no signs of any tubercular disease. The liver was slightly enlarged, pale and flabby, giving no reaction with iodine, and in the intestine three small tubercular ulcers were found just above the ileo-cæcal valve. An iliac abscess gave issue to a large collection of pus.—I am, Sirs, yours faithfully,  
Netley, July, 1892. C. H. Y. GODWIN (Surgeon-Colonel).

<sup>2</sup> THE LANCET, March 9th, 1889.

## “CLASSICAL CULTURE AND THE PROFESSION.”

To the Editors of THE LANCET.

SIRS,—As one of those who consider it a great advantage to the profession that its students should not be compelled to spend valuable time in acquiring an elementary knowledge of languages which are practically useless to them, and of which they speedily forget even the rudiments, I trust you will allow me to point out that Dr. Cuming was perfectly correct in saying that as an element of medical education “Greek seems doomed past recall,” and that Latin is making a bolder fight for its place. Even the Greek alphabet is unknown to most medical men, and of the numerous licensing bodies in the kingdom only a few of the universities exact an acquaintance with it from their medical graduates, whereas some knowledge of Latin is required in a student before he can pass the threshold of any medical school. It may be quite true that a language connected with Greek, as that which we speak is with Anglo-Saxon, is spoken by a few millions of semi-civilised Orientals, that this language boasts of a current literature &c. ; but what has this to do with our professional education? A student of medicine may now become a Fellow of all the Colleges of Surgeons and Physicians and an M.D. of several universities without having wasted a single moment on the Greek grammar, and this fact proves Dr. Cuming’s assertion.

In this connexion it may be remarked that the little knowledge of Greek which they possess proves a really dangerous thing to its medical possessors, for in their anxiety to display it they frequently betray a lamentable ignorance of the laws of their own language. Thus, in showing that they know the Greek word for “head” by pronouncing its derivation with a “k” sound they expose their ignorance of the rule that “c” before “e” is soft in English, and also that lexicographers pronounce such words as “cephalic” and “hydrocephalus” with the sibilant sound of “c.” Moreover, they are generally inconsistent enough to pronounce “hydrocele” and “cœliac” as spelled, showing that their knowledge of Greek is too meagre to enable them to find the derivation of these words. That medical men should attempt to alter the English language and force us to pronounce such words as “ocean,” “hydrogen,” “gynecocracy,” and “gynecology” with a hard sound of “c” and “g” seems the height of absurdity, and yet, through an elementary knowledge of Greek and a gross ignorance of English, some of us seem to be attempting this feat. In Greek, as in many other subjects, it would be well to follow the advice of Pope—

“Drink deep, or taste not the Pierian spring.”

I remain, Sirs, yours faithfully,  
TROJAN.

Aug. 8th, 1892.

## THE CHOLERA IN PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

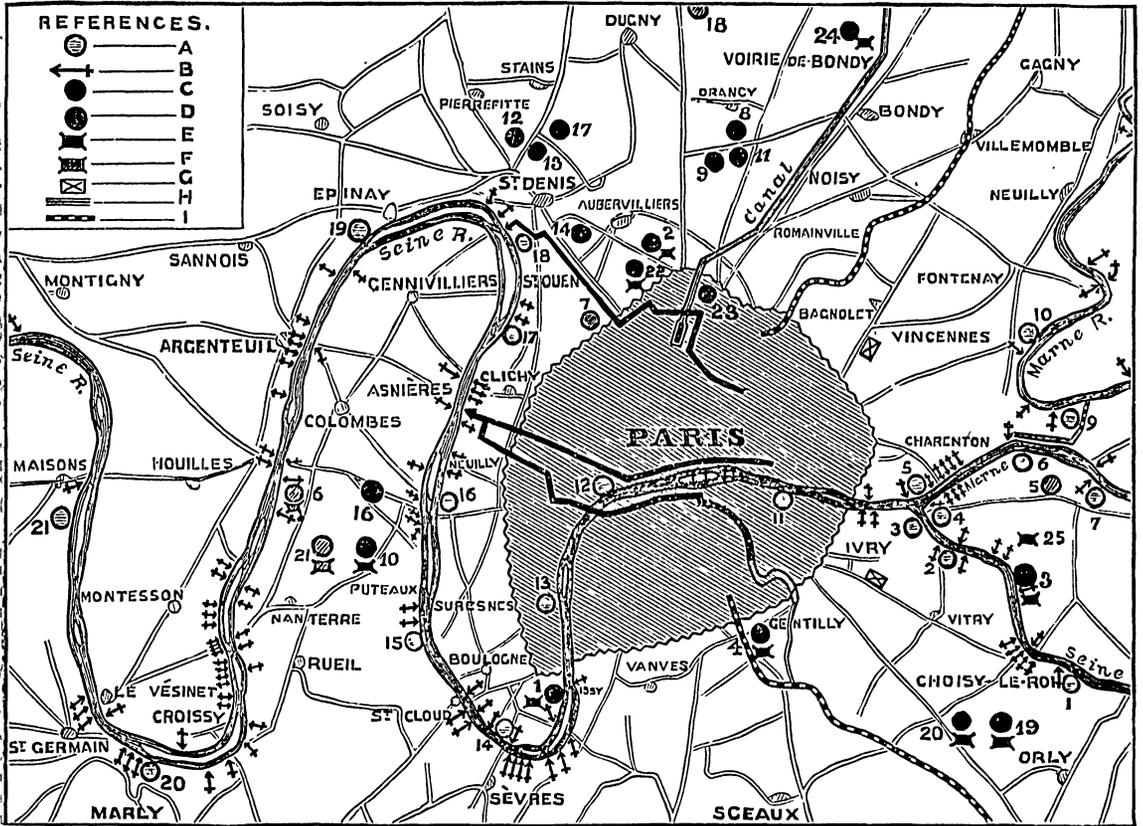

(Illustrated.)

### CONTAMINATION OF THE SEINE.

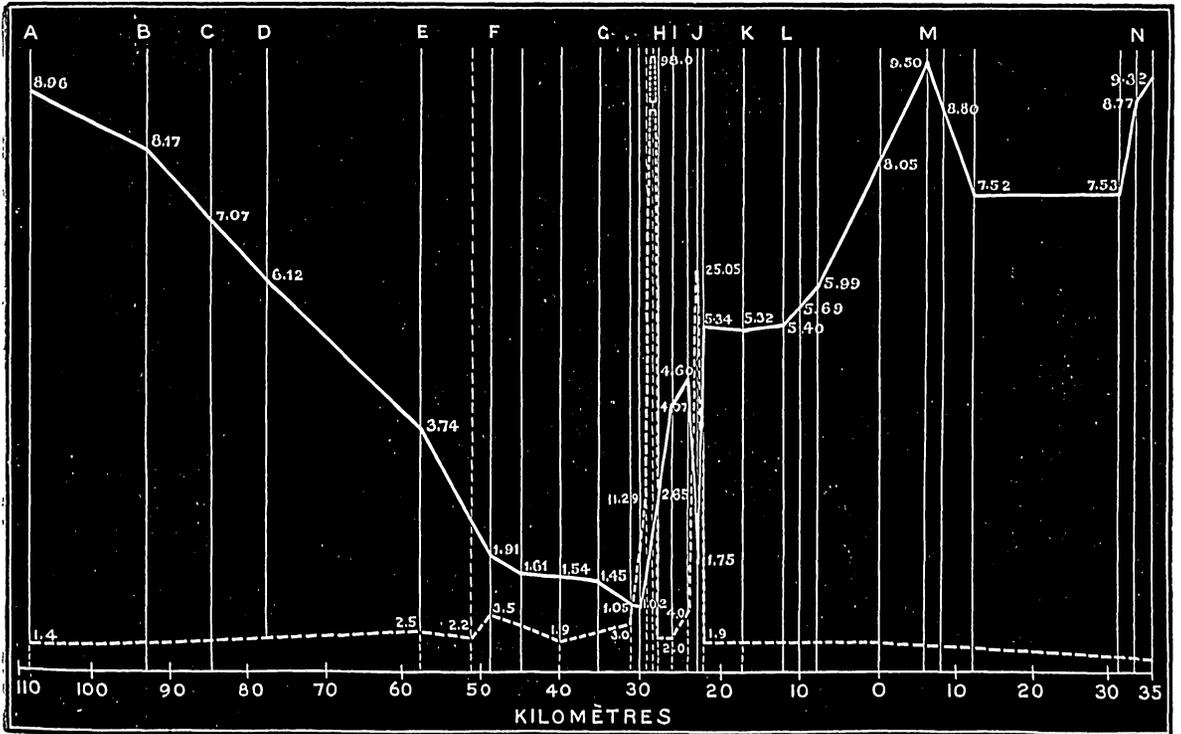

ON all sides evidence accumulates to show that the cholera epidemic has been spreading through drinking the water of the Seine. But it is also very evident that the water of the Seine consumed within the walls of Paris has not caused the epidemic. The mischief arises from the use of water taken from the river after it has passed through Paris. To render the state of affairs thoroughly intelligible I append to this letter a portion of the map of the Seine, published in the official report No. 1303, drawn up at the order of the Chamber of Deputies and illustrating the contamination of the river. Some twenty-two miles up the river and before it reaches Paris—that is, a little beyond Corbeil—the Seine water is limpid, transparent and of agreeable flavour. The experiments which were made by the commissioners appointed by Parliament showed that before reaching Corbeil the Seine water was pure; but at this little town the two rivulets, the Juine and the Essonne, fall into the river. The former of these tributaries, which has its spring near Étampes, is polluted by the drainage from various factories, dye works, paper mills, iron works &c. The waters of the Juine before reaching the Seine are little

better than sewage water. A greasy scum floats on the surface, the water is of a dark colour and bubbles of gas may be noticed. The proportion of oxygen contained in the Juine water is only 6.29 cubic centimetres per litre. Then round and about Corbeil there are fourteen small sewers which fall into the river. These, however, for the most part convey slop water and surface drainage only. As the Seine flows on to Paris it receives other sewer outfalls, but not many, and the water improves in quality. By the time the Seine reaches Choisy-le-Roi and is within seven or eight miles of the walls of Paris it has been found on analysis to contain from 7 to 9 cubic centimetres of oxygen per litre and only some 300 microbes per cubic centimetre. As in the reservoir at Montsouris the extremely pure and excellent waters of the Vanne have generally from 120 to 280 microbes to the cubic centimetre, the Seine water on reaching Choisy-le-Roi may be considered in a fairly good condition. But at Choisy-le-Roi half a dozen local sewers fall into the river, and further down the river, five miles and a half from Paris, there is a large human guano manufactory; these works drain directly into the river and are situated on the water’s edge. A little farther from the river but nearer to Paris there is another dépôt at Maison-Alfort which receives the contents of the Paris cesspools. Then we arrive at the junction of the Marne with the Seine at Charenton. Here, immediately before the Seine meets the Marne, are three water intakes. One of these provides Paris with its supply of drinking water—that is to say, when and where, within the fortifications of Paris, the Seine water is given for drinking purposes it is drawn from the intake close to Charenton. By that time the river has received the foul water from several mills, factories, some guano manufactories and thirty-three sewer outfalls. This water when consumed in Paris generally occasions an outbreak of typhoid fever; and now, when it is supplied to any district in Paris, due warning is published in all the papers and official posters are affixed to the walls. Still, so far this water, though undoubtedly dangerous, does not seem to have occasioned any cases of cholera.

At Charenton the Marne joins the Seine, and in its winding course from Brie-sur-Marne to Paris it receives the contents of twenty sewers. There are numerous water intakes on the Marne, but with one exception they are all beyond Charenton, where the principal sewer contamination occurs. The water from the Marne is employed for local consumption, excepting what is withdrawn from the river at St. Maur, and this is sent to Paris. Finally, it should be observed that there are three intakes of water in Paris itself—one close to the Pont d’Austerlitz and the other two at the other end of the town. However important all these facts may be, they do not seem to bear upon the present epidemic. From a general point of view the water intakes to the east and south-east of Paris are most injudiciously situated, and it is not surprising that typhoid fever should be endemic where such water is drunk; but it is in the suburbs to the north and west of Paris that the cholera has broken out, and there we shall see, by referring to the accompanying map, that the water is much more contaminated than the Marne and the Seine, to the east and south-east of Paris. On both sides of the river, having passed through Paris, it receives the main sewers of the city. Only smaller sewers fall into the river as it goes through the town, and several of these have recently been suppressed. The two islands, the Ile de Paris and Ile de St. Louis, used to drain into the Seine, but the old sewer from the Hôpital de la Salpêtrière has now been connected with the main sewer and no longer falls into the river. Nevertheless, the water does not improve as it passes through Paris, and perhaps the washing of dirty linen in the running stream may have introduced infective materials. Numerous washhouses are constructed on barges which float on the Seine. In any case, as the river issues from the fortification at Auteuil to the south-west of Paris, it already contains from 6000 to 7000 microbes per cubic centimetre and only 6 cubic centimetres of oxygen per litre. Then we come at once to a large dépôt of faecal matter at Billancourt; but at this point, on each side of the Seine, two main sewers have been constructed, which receive the contents of seventeen branch sewers and protect the Seine as it passes through St. Cloud and Boulogne, so that this saves to some extent the water of the two intakes near Boulogne and Suresnes. Between Suresnes and Puteaux these two main sewers fall into the river, and there at once the proportion of oxygen is lowered to 5.3 cubic centimetres to the litre,

J, Opening of the great sewer. K, Barrag de Suresnes. L, Pont de Sèvres. M, La Seine (Pont d'Ivry). N, Corbeil.

NOTE.—The continuous line represents the proportion of oxygen and the interrupted line that of nitrates in the river Seine at various points in its course

and analysis shows the presence of one gramme of nitrates per cubic metre. This varying proportion of oxygen and nitrates is well illustrated in the accompanying diagram showing the progressive alterations in the composition of the Seine water. A little way beyond this gross contamination, at Neuilly, there is another intake of water; and it is just in this neighbourhood—at Suresnes, Puteaux, Nanterre, and Neuilly—that the cholera epidemic began.

From St. Cloud the Seine follows a northerly course and thus reaches Asnières and St. Denis to the north-west of Paris. Here, at Asnières and St. Denis, are the two outfalls of the main sewers of Paris. At Asnières about a third of the sewage is pumped across the river on to the plains of Gennevilliers, where it is used for irrigation purposes; the rest, without any attempt at purification, goes into the river. The result is simply appalling; all the fish are killed and the water thoroughly befouled. The surface of the river is covered with greasy foam. As much as 25 grammes of nitrates (see diagram) have been found per cubic metre of water and the oxygen has almost entirely disappeared; it only amounts to 1 cubic centimetre per litre. As for the microbes they are estimated at 200,000 per cubic centimetre. Heavy deposits of black, foul mud, in some places 10 ft. deep, have been made and there continue on the banks of the river for a great distance. Yet between Clichy and St. Denis, just where these deposits abound, there are two water intakes. From St. Denis the river curves round and again flows in a southerly direction. Round this curve, at a distance of two miles and a half from the Paris main sewer outfall of St. Denis, is the intake of drinking water supplied to the inhabitants of Argenteuil, where the cholera has recently broken out with such violence. Water from this, the Epinay intake, is also supplied to the inhabitants of Sannois and Montmorency, making, with Argenteuil, a total population of about 40,000 persons.

The deposits from the main sewer outfalls, which vary in depth from 10 ft. to 2 ft., are still to be found as far off as Marly; where, by the way, there is another intake of drinking water. The distance by river from the sewer outfall at Asnières to this water intake at Marly is sixteen miles and a half, and at that point the river Seine has received the contents of more than a hundred separate local sewers and all the main drainage of Paris. So great is the contamination of the river that the navigation has been blocked by the sewer deposits. It has been necessary to expend large sums of money to dredge out of the water the heavy filth brought by the sewers.

Referring again to the accompanying diagram it will be seen that as the Seine flows away from Paris the sewage becomes more and more diluted, the population on either bank is less dense and the sources of contamination are less frequent. A little beyond St. Germain the proportion of nitrates has fallen to 2·5 grammes per metre cube, and there are now 3·7 cubic centimetres of oxygen per litre. At Poisy there are 2·2 grammes of nitrates, and 6 cubic centimetres of oxygen. At Mantes there is 1·4 gramme of nitrates to the cubic metre, and the Seine has recovered the proportion of oxygen it contained before reaching Corbeil—namely, 9 cubic centimetres to the litre, or 0·9 per cent. Mantes is at a distance by river of fifty-four miles from the outfall of the Paris main sewers. But though the water at Mantes has recovered the proportion of oxygen it loses after passing Corbeil, traces of infection are to be found much further, and they daily continue to extend their influence. Thus in 1875 the contamination was not found beyond the lock of Mézy, a distance of forty-six miles; but in 1880 it had already reached Port Villey, a distance of seventy-six miles. Thus we may conclude that Rouen will soon be contaminated by the sewage of Paris.

As I have already explained (see THE LANCET, July 9th) the districts outside Paris are at the mercy of water companies which possess monopolies according to treaties drawn up twenty and twenty-five years ago. These treaties contain no clause by which the companies can be prevented from supplying the Seine water. When the treaties were drawn up the Seine was not contaminated as it is to-day, nor was the danger of such contamination so fully realised. These treaties in some instances have still thirty-five years to run. The city of Paris will soon have spring water sufficient to render unnecessary the use of water from the Seine. But what will become of those suburban districts where the cholera has prevailed since the month of April and where many hundred deaths have already occurred from this cause? The accompanying map explains, more eloquently than any words I can write, how the water is contaminated and

how there are intakes of water just where the contamination is most intense. Such a danger cannot be allowed to continue, whatever may be the terms of the treaties with the water companies.

## BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

### *“Moving with the Times.”*

THE thirst for change and variety exhibited in the present day is a prominent feature in town populations. No doubt it is in some measure the outcome of the rapid rate of living, the excitement and high pressure under which the conditions of life are fulfilled, and the crowding together in limited areas. Rest and desire for a brief period of tranquillity is the necessary aspiration after nerve wear and tear prolonged through many months, hence the migration to the coast and the desire to wander far from the busy hive of industries and the noise of ceaseless work. The facilities afforded by railway companies increase the wish to remove away from toil and care, the supply in some measure raising the demand, and though “these English people take their pleasure sadly,” often spending the greater part of the time at their disposal in travelling, they appear to be satisfied, and to flatter themselves that they have created a reserve of health by madly rushing about in midnight trains and subjecting themselves to physical discomfort and self-denying restraints. This time of the year affords abundant examples of ill-regulated change.

### *The Queen's Hospital.*

An interesting ceremony took place at this hospital on the 8th inst., when the Rev. J. C. Blissard was presented with a life-size portrait of himself, to be hung in the board-room of the hospital. For ten years as chairman of the committee Mr. Blissard has rendered exceptional services to the hospital, the portrait being intended to remain as a memento of his valuable aid to the institution. Alderman Clayton made the presentation in appropriate terms and highly eulogised the work done by the late chairman. Mr. Bennett May, chairman of the Medical Committee, endorsed the remarks, and observed that the relations of that committee with Mr. Blissard had always been of the most satisfactory and cordial character. Lord Leigh also presented an illuminated address to Mr. Blissard expressing the confidence and respect with which he had conducted the affairs of the hospital. A suitable reply was made by the ex-chairman.

### *Medical Magistrate.*

Among the recent additions to the Commission of the Peace for the city is the name of Dr. Charles Warden, who for many years has been one of the surgeons to the orthopaedic hospital—a compliment well deserved and upon which he received the congratulations of many friends.

Aug. 10th.

## MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

### *Crematorium.*

FOR some years past a crematorium has been under construction at the Manchester Southern Cemetery. The building is now finished, and last week an experimental cremation took place there with satisfactory results. It is anticipated that the crematorium will shortly be in complete working order. It has been built by a private company.

### *Victoria University.*

At the recent final examination for the degree of Bachelor of Medicine a larger number of candidates presented themselves than has hitherto been the case. The proportion of men who passed was fairly large; that of honours gained was small. It is a striking feature that many men who have within the last two or three years proceeded to this degree have not taken the double qualification of the London colleges, so that it appears as if in the future the degree will be looked upon by Manchester students as the M.B. Edin. is regarded by students of that school—their qualification as well as their academical degree.

*Infirmary Extension.*

The voting papers for the poll of trustees which is to decide whether or not the infirmary is to be extended in its present situation were sent out last week, and are returnable by the end of the present one. The press is taking an active part in the controversy by means of leading articles, and nearly every day there are published numerous letters from private correspondents on both sides of the question, showing a deep interest, not only on the part of the medical men directly concerned, but on that of the general public.

Manchester, Aug. 10th.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

*The British Medical Association Meeting in Newcastle, 1893.*

THE news that the British Medical Association has accepted the invitation to Newcastle in 1893 has been received here with great pleasure. It is now, I believe, about twenty-six years ago since it met there. Newcastle has since then been transformed from an ancient town to a modern city and its population has doubled. Together with the sister borough, Gateshead, from which we are separated by the Tyne, but with which we are connected by some magnificent bridges, we make up, with suburbs, about 500,000 inhabitants; but taking the neighbouring towns from Durham to North Shields and within fifteen minutes or so by rail, we can include a population of over 1,000,000. I hear that a meeting is to be held on the 12th inst. (under the genial auspices of the President-elect, Professor Philpson) to make all preliminary arrangements, and it is certain to be well attended.

*County Medical Officers of Health.*

At a late meeting of the North Riding County Council it was resolved that, on an application being transmitted to the clerk of the County Council from any sanitary authority that their medical officer of health may be assisted by the medical officer of health of the Riding in making an inquiry into the cause of an outbreak of infectious disease, such application should be forthwith transmitted to the chairman of the Sanitary Committee, who, if he thinks it desirable, shall have power to direct the medical officer of health to proceed and assist in making such inquiry. The question of appointing a county medical officer for Northumberland came up last week before the County Council. In a forcible speech Dr. Trotter of Blyth said that they would soon be in Northumberland, in this respect, the one dark spot on the sanitary map of England. Last year, he said, there were thousands of cases of typhoid fever due to bad sanitary conditions, and if the Council did not do all the Local Government Board gave them power to do, they would be morally responsible for any deaths that resulted from disease which was allowed to exist in consequence of their neglect. The Council, however, did not see their responsibility in this matter, so that the appointment of a medical officer was for the present not carried.

*The Measles Epidemic at Jarrow.*

At the last meeting of the Jarrow Town Council reference was made to the epidemic of measles which still exists, and it was stated that during the month of July alone there had been 114 cases.

*Small-pox at Middlesbrough.*

At a meeting of the Middlesbrough Sanitary Committee, held on August 2nd, it was stated by Dr. Malcomson, the medical officer of health, that there had been seven cases of small-pox in two centres since the last meeting. The medical officer further reported that he had not been able to trace any connexion between either of the centres of infection and any of the cases reported previously.

*Northern Friendly Societies' Demonstrations.*

These demonstrations of our friendly societies in aid of local hospitals and other charities are bearing good fruit. At the last meeting of the Hartlepool Hospital Dr. Gourley stated that the result of the last parade enabled him to hand over about £60 to the hospital.

*Sunderland.*

Mr. A. E. Harris, medical officer of Sunderland, whose services the borough is about to lose, in his annual report mentions that there has been a decrease in the marriages to the amount of 124 as compared with 1890, and there has also been a decrease in the births of 359—in other words, the birth-rate was 37·7 per 1000 in 1891, while the average rate from 1874-90 was 40·4. As to the increased fatality from measles, Mr. Harris thinks that the great circumstance at work has been the increased aggregation of children at schools, and he thinks that less zeal on the part of the School Board officers would undoubtedly tend to the greater health of the children, and would also lessen the number of cases arising from such diseases as measles. Mr. Harris is in favour of the appointment of a School Board medical officer to whom parents could send their children for examination when they appeared to be ill. On Monday night last as a number of pauper children were proceeding from school to the Sunderland workhouse they commenced to pick berries from the laburnum trees in the grounds, and a quantity were thus eaten. Several of the party became seriously ill, and when medical aid was sought it was necessary to use the stomach pump, four girls being in a collapsed condition on Tuesday morning. Many were still ill, but it was hoped they would all recover.

*The late Dr. Maclagan of Berwick.*

The promoters of the memorial of the late Dr. Philip Maclagan of Berwick have agreed to perpetuate his memory in the border town by erecting a drinking fountain and bronze medallion, to cost not less than £150. The residue of the fund is to be placed at the disposal of the Misses Maclagan. I understand that the fund reaches about £600.

Newcastle-upon-Tyne, Aug. 10th.

## IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

*Royal College of Surgeons.*

At a meeting of the President, Vice-President and Council of the Royal College of Surgeons in Ireland, held on Thursday, Aug. 4th, the following were elected Dental Examiners: John Barton, F.R.C.S.I.; Henry Gregg Sherlock, F.R.C.S.I., L.D.S.; William Stoker, F.R.C.S.I.; Thomas Studley, L.D.S.; Charles Wall, L.D.S.; Montgomery A. Ward, F.R.C.S.I. The examinations are held in November, February and May.

*The late Dr. Henry Croly.*

The following resolution was adopted at the last meeting of the guardians of the South Dublin Union:—"That the board has learned with deep regret of the death of Dr. H. Croly, who for a long period discharged with ability and skill the duties of medical officer in the Rathfarnham district of the union, and had during all that time proved himself a kind and considerate friend to the poor; and that copies of this resolution be sent by the clerk to the relatives of the deceased."

*"Charming" Erysipelas: Charge of Manslaughter.*

On Saturday, July 30th, an inquest was held in Lurgan on the body of David Archer, a builder, who had died on the previous day after a brief illness. From the evidence it would appear that deceased had suffered from erysipelas of the right leg. He was attended by Dr. Agnew and Dr. Magennis, both of Lurgan. They saw and dressed the patient's leg on Sunday night and Monday morning. On the Monday evening they noticed that Archer was a great deal worse, and on examining the limb they found that their dressing had been removed. It would appear that Owen McIlmurray, who is a "charm doctor" and saw sharpener, was sent for on the Monday after the doctors paid their morning visit to say a "charm" for the removal of the disease. Archer's sister objected, but he and his wife were agreeable. He pulled off the dressings and applied butter and flour and then bandaged the limb in flannel. The two doctors, in the very difficult circumstances in which they were placed, retired for a consultation, and as they were thoroughly agreed that the alteration in the treatment had been attended with very serious consequences, and as the life of Archer seemed to be in extreme danger, he being himself delirious, they told his sister plainly their

opinion, and, after speaking to Archer's wife, they were instructed to take charge of the case again. They removed the new dressings which the "charmer" had applied and resumed the original plan of treatment, and gave such remedies as they considered suitable to the case. On the Tuesday and Wednesday the disease remained stationary, but on Thursday the patient became worse and died on Friday from the effects of the erysipelas. The jury returned a verdict of manslaughter against McIlmurray, who was arrested and brought up at the Lurgan Petty Sessions and returned for trial, bail being accepted. It would appear that McIlmurray not only repeated a charm, but tore away the dressing applied by the doctors to the limb and put on a layer of butter and flour, which he rubbed until sores were produced. The medical men found a flannel bandage embedded in the sores, and, notwithstanding all they could do, Archer died from aggravation of the disease, Dr. Magennis swearing that death was caused by McIlmurray's interference.

#### *Queen's College, Belfast.*

The results of the summer examinations of the Royal University, which were published last week, show that Queen's College, Belfast, again obtains the first place among the affiliated colleges. The students from our local College have won twenty-eight first honours and forty second honours, with thirteen first-class exhibitions and twelve second-class, the aggregate value of these being £662. Indeed it is doubtful if the College has ever been so successful, as a few facts will show. Thus, at the first University Examination in Arts one of its students was first in Latin, another first in experimental physics, but in mathematics the Belfast men carried off all the firsts (including a first) which were given except one—that is, five out of six. At this examination the successful Belfast students were awarded six exhibitions of £30 each and three of £15. At the second University Examination Queen's College won every first honour in mathematics that was given, together with other firsts in French, in mathematical physics and in experimental physics (first of first), and was awarded three exhibitions of £36 each and four of £18 each. The successes at the B.A. degree are still more brilliant. A Belfast Queen's man is first of first in ancient classics, another first of first in mathematical science and a third in experimental science. One of them wins the first of the first-class exhibitions, a valuable prize of £42, while two others follow closely and carry off exhibitions of similar value, and three others obtain £21 (each) exhibitions. A Belfast student gains a first in logic, metaphysics, ethics and history of philosophy, and another a first in civil and constitutional history, political economy and jurisprudence. At the LL.B. degree two of the Belfast alumni carried off all the prizes awarded, one of them gaining a first-class and £42 in money and another a second with £21. In the School of Engineering the College won an exhibition, and at the First Examination in Medicine gained all the firsts in zoology (including, of course, the first of first) and in experimental physics, as well as a first in botany and a first-class exhibition of £20. The foregoing record is one to be proud of and is most satisfactory to all those who take an interest in Queen's College, Belfast. The fact, that at these recent University examinations—examinations conducted by experts in the several subjects, and at which candidates from colleges in every part of Ireland presented themselves—Queen's College, Belfast, has gained the premier position, shows that at no time since its foundation in 1849 was this school of learning in a more efficient condition than at present.

#### *Handsome Donation.*

The Cork hospitals have received £1000 from Sir John Arnott, D.L., a well-known Cork citizen.  
August 6th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

#### *The Cholera Epidemic in Paris and its Environs.*

THE most notable contribution to our knowledge of this disquieting outbreak made since my last letter is undoubtedly the official report of the Committee of Investigation of the

Comité Consultatif d'Hygiène de France handed in on the 8th inst. This committee is composed of Professor Proust and Drs. Netter, Thonot and Ogier, all men of acknowledged competence in sanitary science. Optimism is the prevailing note of the report, the terms of which are certainly calculated to reassure the most timid. Take for example the opening sentence: "A l'heure actuelle on peut dire que l'épidémie a presque totalement disparu de la banlieue [suburbs] et de Paris." The report goes on to state that the last fortnight has brought no modification to the curious and characteristic topography of the epidemic. Those suburbs which draw their water-supply from the Marne and the Oise have remained absolutely free from the disease, which has only made its appearance in suburban districts supplied with Seine water. This observation is rendered more important by the fact that the epidemic raged with most intensity in those parts (Saint-Denis, Saint Ouen, Aubervilliers and Argenteuil) where the Seine water distributed for consumption was at its maximum of pollution. The committee comes therefore to the conclusion that the sole factor in the determination of cholera *vidi* is the drinking of Seine water, this indispensable condition explaining the non-diffusibility of the disease. The report states unambiguously that not a single *legitimate* case of cholera has originated in Paris itself, every undoubted case having been proved to have been contracted in the suburbs. In four instances, at most, these imported cases have given rise to fresh cases, but the tendency to further propagation of the epidemic has been *nil*. "Paris doit donc être considéré comme indemne." After reminding us that up to the present the army (which is supplied either with spring water or with water that has undergone a process of boiling and filtering) and the employés of the great companies and the seaports have escaped the disease, the report concludes with this encouraging sentence: "Il ne nous est pas permis de préjuger l'avenir, mais nous pensons qu'à l'heure actuelle nous pouvons considérer tout danger comme écarté." Let us hope that this pronouncement will not be falsified by the expansion of the dread disease in the near future. I may add that in the last official mortality tables for Paris (issued on the 4th inst.), and having reference to the week ending July 30th, twenty-one deaths of persons above five years of age are attributed to diarrhoea, as against fourteen for the preceding week and an average for the last five years of six cases. The cholera column remains as usual—blank.

Paris, Aug. 10th.

## NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

#### *Quarantine at New York.*

THE report of the health officer for the year 1891 has just appeared and some of its statistics are of general interest. The number of emigrants from transatlantic ports inspected during the year was 445,290. This number was largely in excess of the former year, showing that emigration from Europe is on the increase. The health officer is of opinion that unless the civil authorities exercise greater care in the inspection of emigrants in relation to their sanitary, physical and moral status, the country will in the near future be subjected to sanitary conditions and social and political evils much worse than those which now exist among the populations of the old world. With the exception of one case of typhus fever, the only quarantinable diseases found on board vessels during the year were small-pox, scarlatina, diphtheria and measles. During this period 2730 passengers were removed from vessels to the hospitals for observation, owing to their exposure to infectious diseases other than yellow fever. Thirty vessels arrived from Brazilian ports, which gave a history of sickness and death from yellow fever, either when in port or within the first few days after departure. An earnest effort has been made to ensure that vessels which trade at these ports should anchor at such a distance from the wharf that the infected atmosphere which prevails near them may not affect the people on board, and to have the cargo lightered from the wharf to the vessel, and thus to minimise the danger of infecting the vessel from the dirt which is frequently taken on board with the cargo when it is carried directly from the dock. The total number of cases of yellow fever on vessels arriving at New York in 1891 was seventy. These were received upon a vessel anchored in the lower bay, where they

were treated. The health officer explains at length his management of the cholera ships which arrived in 1890. The facilities for the care of such cases at that time were very defective and gave rise to much criticism. Great improvements have since been made, and he now believes that the quarantine arrangements can meet any emergency.

#### *Precautions against Cholera.*

Amongst other precautions against cholera is a provision requiring our consuls to secure the disinfection of rags at foreign ports, from which they are baled and sent to this country. Our consul at Ghent has issued a circular letter explaining the regulations for disinfection as follows: (1) Boiling in water not less than one hour; (2) exposure to steam not less than one hour, the steam to be of a temperature not less than 100° C., or greater than 115° C.; (3) exposure not less than six hours to sulphurous acid gas made by burning not less than 3 lb. of roll sulphur to each 1000 cubic feet of space; (4) exposure not less than six hours to an atmosphere containing 3 per cent. of sulphurous acid liberated from its liquid state (liquid sulphur dioxide). The Secretary of State has instructed our consular officers in Eastern European Russia, Persia, Calcutta and the western shores of the Red Sea to require rigid disinfection against cholera and to discourage exportation to the United States from infected districts.

#### *Vaccination of Steamship Passengers.*

A passenger on board a Cunard steamship prosecuted the company for what was alleged to be forcible vaccination. Small-pox had appeared on the vessel, and vaccination was recommended to passengers by the surgeon as a means of protection, and also to prevent detention at quarantine. The Court decided that vaccination of an immigrant passenger on a steamship coming from a foreign country is not an unlawful act when his whole conduct indicated that he desired it to be performed, so that he might receive a certificate which would save him from detention at quarantine.

#### *Health of New York for 1891.*

The total number of deaths for the past year was 43,695 in an estimated population of 1,680,000, which is equivalent to a mortality rate of 25.9, against 24.5 in the previous year. The heavy increase in the death-rate is ascribed to the ravages of influenza, but as that disease was epidemic in 1890 the explanation does not appear sufficient. Scarlet fever caused 1220 deaths against 408, and measles 1663 as compared with 730. The *New York Medical Journal* believes that the steady increase in the death-rate of the city was referable in great measure to preventable causes; other influences may expand the death-rate, but none more surely than incompetent sanitation.

New York, Aug. 3rd.

## AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

#### *The Outbreak of Small-pox.*

A SENSATION was caused in Melbourne some days ago by the announcement that a case of small-pox had been discovered at a large hotel in Collins-street. The patient was an Englishman, who had only a few days previously landed from a mail steamer. On receiving notice that the disease was really small-pox, the health officers immediately placed a cordon of police around the hotel and imprisoned the inmates until such time as they were all vaccinated and the whole place fumigated. The patient was removed to the Contagious Diseases Sanatorium, his effects burned, and all papers, books &c. in the reading-room of the hotel treated in a similar manner. Those of the inmates who objected to vaccination were held prisoners until they submitted, which in the end they all did. A notice was issued by the Board of Health calling on all passengers by the steamer in question to report themselves to the medical officers throughout the country and to be vaccinated forthwith. Instructions were issued to the medical profession to carefully watch these passengers and to report at once to headquarters any sign or symptom indicative of small-pox. A close scrutiny of the other passengers resulted in the finding of a girl suffering from the dire disease

and she and her family were at once isolated in their own house. The girl was then transferred to the sanatorium, the rest of the family were vaccinated and the house and its contents fumigated. Telegrams were sent to the health authorities at Sydney, whither the steamer had proceeded, and to the other colonial governments, officially informing them of the outbreak. The steamer had already landed her Sydney passengers before the information was received from Melbourne, but the vessel and crew were at once placed in quarantine. The New South Wales Board of Health immediately issued notice to all passengers as to vaccination and reporting themselves, as the Victorian Government had done, and published the names of the defaulters in the daily newspapers. These very strict precautions have had the effect of confining the disease to the passengers and of enabling the authorities to deal with it satisfactorily. The Queensland passengers who transhipped at Sydney were all stopped at Brisbane and the whole of them quarantined. Up to the present not more than a dozen of the crew and passengers have developed the disease, and they are all isolated in the quarantine grounds of Melbourne, Sydney, Brisbane and Adelaide. There has been one death, a seaman who died at Sydney.

People at home who are familiar with small-pox cannot very well understand the extreme sensitiveness of the Australians on the matter. Small-pox is not endemic here, and it only occurs when brought from other countries. We rely on our health regulations to keep the disease away, and on the whole the precautions taken at the different ports have been successful.

As a consequence of this immunity vaccination has been very much neglected. In my last letter I drew attention to this matter in connection with the statistics lately issued by the New South Wales Government. I pointed out that we were growing up practically an unvaccinated nation. It is only when small-pox is at our doors that we submit to be vaccinated, and in proportion to the amount of public terror does the percentage of the vaccinated rise. I have no doubt that if this present visitation had spread the whole of the population would have desired to be vaccinated.

The steamer's last call before reaching Australia was at Colombo, where small-pox was rife, on May 30th. The passengers landed, and there can be no doubt the disease was contracted there. There was no sign of small-pox on the steamer's arrival at Albany ten days later, and she was granted a clean bill of health, which was endorsed at Adelaide a few days afterwards, and on this clean bill she was passed at Melbourne. The health authorities at Melbourne blame the officials at Adelaide and the ship's surgeon for concealing the fact of small-pox being on board. But, as the surgeon on board points out in a communication to the press, if the disease were contracted at Colombo its period of incubation would only have elapsed on arrival at Melbourne.

There is one thing this outbreak clearly proves, and that is the utter uselessness of the single examination at Albany, where it is proposed to establish the Federal Quarantine station. I have no doubt that for the future the oversea ships arriving from the East will be carefully examined at each port of call along the Australian coast, and that the intercolonial bills of health, even if clean, will not be received as a guarantee of the state of the ship carrying them.

June, 1892.

## MEDICAL TRIALS.

#### ALLINSON v. THE GENERAL MEDICAL COUNCIL.

THIS action came before the Master of the Rolls, Lord Justice Bowen and Lord Justice Kay on Monday last. It is, as our readers are aware, a declaration that the erasure of the plaintiff's name from the Medical Register was invalid and void, and a demand for an injunction to restrain the defendants from erasing the name or publishing the decision or sending a notification of it to the Royal College of Physicians, Edinburgh. The facts of the case are familiar. The Divisional Court, upon the application of the defendants, dissolved the interlocutory injunction, and from this order the plaintiff appealed. Mr. H. S. Young stated the case for the plaintiff. The counsel for the defendants (Mr. R. T. Reil, Q. C., and Mr. Muir Mackenzie) were not called upon. The Master of the Rolls said that the defendants were a body which had a duty to perform imposed upon them by statute, a duty which was somewhat like a judicial duty. The defendants had performed that duty and apparently published the result of their decision. There was no evidence upon which it could be suggested that they had performed their duty dishonestly. They could not, therefore, be held liable for the publication, because the occasion would be privileged. Nevertheless it was argued that the Court ought at this stage of the action to restrain the defendants from publishing their

decision and notifying it to the Royal College of Physicians at Edinburgh. Such a contention was hopeless. The appeal must therefore be dismissed. In this decision Lord Justices Bowen and Kay concurred.

#### ACTIONS AT DERBY BY THE APOTHECARIES' SOCIETY.

##### JUDGMENT.

At the Derby County Court on Tuesday his Honour Judge Kenelm Digby gave judgment in the three actions brought by the Apothecaries' Society against Christopher Jones, herbalist, of Derby, to recover three separate penalties of £20 against the defendant for three alleged offences against the provisions of the Statute "for better regulating the practice of apothecaries throughout England and Wales." The case, which was tried at length a fortnight ago, and in which his Honour reserved judgment, has excited considerable attention among the medical men of the neighbourhood. After detailing the evidence and observing that according to the defendant's card he removed tumours, cancers and abscesses without cutting, also removed the germs of consumption even when the case was given up, the judge went on to say he had stated the evidence in detail in order to make it clear that the special case relied on as "acting or practising as an apothecary" was not an isolated instance of advice asked and given as to an appropriate medicine for a particular ailment, but, as he found in fact, was one of a series of acts. His Honour thought this was a case where the plaintiff acted as an apothecary within the meaning of the Act and therefore in this (the first of the three actions) he gave judgment for the plaintiffs for the penalty of £20.

With reference to the other two cases His Honour said the plaintiffs had made each instance of the visits to the defendant by different persons the foundation of a separate action and claimed three penalties as for three distinct offences. It was not necessary for him to attempt to define what would constitute a separate offence under the Act of George III. All that it was necessary for him to say in the present case was that he felt bound to follow the ruling of Lord Tenterden in the case of "Apothecaries' Company v. Bentley," and to decide that the advising and prescribing to three different patients consecutively on the same day constituted but one offence under the Statute; and therefore that the judgment which he had already given in the first of these cases was a bar to the recovery of further penalties by the plaintiffs in the second and third cases. In these cases, therefore, there would be judgment for the defendant; and in each case the costs would follow the decision.

On the application of Dr. Rogers and Mr. Potter His Honour granted leave to appeal.

#### PROSECUTION OF DRUGGISTS.

##### TINCTURE OF OPIUM OR LAUDANUM?

At the Nottingham Guildhall on Tuesday last three local druggists were charged, under the Act for the Prevention of Adulteration of Food and Drugs, with selling laudanum which was not of the nature, substance and quality demanded by the purchaser. Mr. F. E. Harris (from the office of the town clerk) appeared to prosecute.

In the first case the accused was charged with selling six ounces of tincture of opium which was not of the nature demanded. The inspector of nuisances for the borough deposed that he paid 1s. 6d. for six ounces of the tincture, which he divided into three parts and submitted to Dr. Truman, who certified that the fluid contained no morphia at all. In answer to the defendant, witness stated that he did not ask for tincture of opium, but simply for tincture of laudanum. Dr. Boobyer, medical officer of health for Nottingham, said that the only opium permitted to be used by the British Pharmacopoeia was that obtained from Asia Minor, which contained about 10 per cent. of morphia. Anything sold as laudanum without specifying any particular laudanum should be made according to the Pharmacopoeia prescription. If the quality was allowed to vary children might be poisoned in some cases and in others they might be treated ineffectually. The defendant said that in the course of an experience extending over twenty-one years he had, in company with others, always regarded tincture of opium and tincture of laudanum as two distinct drugs, laudanum only being supplied to the general public. The preparation supplied to the inspector was asked for under the name of laudanum and it was a preparation made on the premises from crude opium instead of dried opium, and to that extent it might be possibly weaker than the Pharmacopoeia prescription. He did not admit that the drug contained no morphia. On cross-examination, he said that he had not had his sample analysed because he thought he was right. If the inspector wanted tincture of opium he should have asked for the Pharmacopoeia prescription. The Bench said the case was proved, and defendant would be fined £5.

In the second case the druggist was charged with a similar offence, the analyst's certificate showing that instead of 754 of morphia there was but 206 in the drug. In answer to a question raised by the defendant, Dr. Boobyer said that he did not recognise any legitimate distinction between tincture of opium and laudanum. Laudanum was the popular designation and synonym. The Pharmacopoeia was a classic work and did not recognise popular designations. The defendant said that he had circulars in his hands from some of the largest wholesale chemists in the country, in which tincture of opium and laudanum were quoted separately. The magistrates said that in this case they would give the defendant the benefit of the fact that the drug contained a little morphia, and he would be fined £3.

In the third case the accused was summoned for selling five ounces which only contained 51 instead of 754 of morphia. The inspector stated that defendant said to him, "Do you want the B.P.?" and witness replied, "Yes, certainly." For the defence Mr. Lindford, F.C.S., chemist to Messrs. Lofthouse and Salmer of Hull, said that he analysed every chest of opium which came into his laboratory, and the tincture of opium in question was of full strength. The analysis of opium was not a very easy one, and he had doubts about the analysis submitted to the Court. The defendant said that when he ordered the drug he specially mentioned that he wanted B.P. quality, and he paid the market price, 3s. 2d. per pound, for it. He sold the article in good faith, and he would ask that the third part in the possession of the inspector might be

analysed by the Government analyst at Somerset House. The magistrates said that they were inclined to believe that the article was in good faith, and they would inflict no penalty.

#### MEDICAL NOTES IN PARLIAMENT.

##### *The Housing of the Working Classes.*

MR. CHANNING has given notice that during next session he will introduce a Bill to amend the Houses of the Working Classes Act, 1890, and to give further powers to local authorities for the provision of houses or cottages with land attached in rural sanitary districts.

##### *The Government of Egypt.*

Sir Charles Dilke will call attention next session to the declarations of successive administrations with regard to the future government of Egypt and move an address to Her Majesty praying that she will be graciously pleased to direct the resumption of the negotiations of 1887 for the neutralisation of Egypt under conditions which will enable Her Majesty's Government to secure the permanence of the arrangement.

##### *Dangerous and Unhealthy Labour.*

Mr. Thomas Bayley has tabled a motion for next session, declaring that the working hours of persons employed in dangerous and unhealthy trades should be regulated by law.

##### *Death from Anthrax in Sussex.*

In the House of Commons on Thursday Mr. Chaplin stated in reply to Admiral Field that he had received reports from the medical officer of health and the sanitary inspector as to an outbreak of anthrax on a farm at Chalvington, Sussex. There were attacked by the disease twenty-one cattle and two horses, all of which had died. He regretted to say that a farm servant, by whom one of the animals was killed, became affected with the disease and with a fatal result.

##### *Typhus Fever in Lewis.*

Mr. Galloway Weir addressed a question to the Lord Advocate with reference to an epidemic of typhus in the island of Lewis. The Lord Advocate replied that no information had reached any of the officials concerned as to the alleged epidemic, but inquiry was being made, and if necessity arose steps would at once be taken to deal with it.

##### *The Prevention of Pleuro-pneumonia.*

Mr. Chaplin, in reply to Mr. William Field, said it was not his intention to recommend the institution of scientific experiments to try the efficacy of inoculation as a preventive of pleuro-pneumonia. Numerous investigations had already been made.

##### *The Seizure of Unsound Meat.*

Mr. Chaplin, answering another question by Mr. Field, said it was a mistake to suppose that animals were passed as sound in open market by any Government inspector. The power of the medical officer to seize meat which appeared to him to be unfit for the food of man, was contained in Section 116 of the Public Health Act, 1875, and meat which had been so seized might be destroyed by order of the justices.

##### *The Proposed Fever Hospital in Tottenham.*

Several questions were addressed to Mr. Balfour with regard to the proposed erection of a fever hospital in Tottenham by the Metropolitan Asylums Board. The President of the Local Government Board, he said, had given the matter the most careful consideration and had sanctioned the acquisition of the site.

## Medical News.

UNIVERSITY OF LONDON.—At the Intermediate Examination in Medicine recently held the following candidates passed:—

*Entire Examination.—First Division:* Alfred Armer, of Guy's and St. Bartholomew's Hospitals; Dorothea Calne, of London School of Medicine for Women; Thomas Varley Cunliffe, Joseph Percy Hall, and Percy McDougall, B.Sc., of Owens College; Percy J. Edmunds, B.Sc., of University College; Joseph Ganner, of Queen's College, Birmingham; Sinclair Gillies, of St. Bartholomew's Hospital; Henry Gwynne Lawrence, of St. Mary's Hospital; Fredk. Charles Sprawson, of King's College; Edwin Claude Taylor, of Guy's Hospital.—*Second Division:* Henry Russell Andrews, of London Hospital; E. Louise C. Appel, B.Sc., and Helen Swatman, of London School of Medicine for Women; Joseph Ashton and Daniel Edward Evans, of St. Mary's Hospital; George F. Bergin, of Bristol Medical School; John Smedley Boden, of King's College; James Jordan Coleman, Henry William Collier, James H. Horton, Benjamin Arthur Richmond, Phillip Northcott Vellacott, and Christopher Frank Wakefield, of Guy's Hospital; Percy Robert Cooper, B.Sc., and Charles Herbert Melland, of Owens College and Manchester Royal Infirmary; Francis G. Crookshank, T. Villiers Crosby, Archibald Hugh P. Dawnay, Joseph Cooto Hibbert, Richard Llewellyn Jones, John Polo Kitson, David Morrison, Ernest Elias Murray, and George Harold C. Way, of University College; John Carmichael Edgar, Thomas Gregory, and M. J. O'Flanagan, B.Sc., of Owens College; George Gilbert Genge, Alfred Lucette Hoome, and Win. Douglas Knocker, of St. Thomas's Hospital; Henry Tregolles Gillett, Thomas Percy Legg, and

Fredk. W. Robertson, of St. Bartholomew's Hospital; Archibald G. Gullan, of University College, Liverpool; Robert Hunter Steen, of Queen's College, Belfast.

**Excluding Physiology.**—*Second Division:* Joseph Norwood Brown, Geo. Wilfrid Gostling, Arthur Hunnard, Austin Edward Reynolds, Sidney Edward Shoppee, and Joseph Edward Walte, of University College; John Samuel Chater, of St. Bartholomew's Hospital; Matthew L. G. Hallwright, of Queen's College, Birmingham; George Robert Harcourt, of St. Thomas's Hospital and King's College; Sydney Price James, of St. Mary's Hospital; Amella M. Le Pélley, of London School of Medicine for Women; W. Matthews Price, of Guy's Hospital; William Smith, of Bristol Medical School; Arch. Young, of Sheffield Medical School and University College.

**Physiology only.**—*First Division:* Wm. Branson, of Sheffield Medical School and University College; Courtenay Rossiter Colley and Edward F. H. Hardenborg, of Guy's Hospital.—*Second Division:* Richard Babb, of London Hospital; D. Arnold Chaning-Pearce and Noel Instone, of Guy's Hospital; Seymour Farrage Gibbs, of St. Bartholomew's Hospital; T. Oates Halliwell, of St. Thomas's Hospital; Herbert Wheatley Hart, of Westminster and Guy's Hospitals; and King's College; John Nicholson, of Yorkshire College; Hugh Stanley Revell and William Henry Stoddart, of University College.

The following candidates passed in Honours in the respective subjects:—

**Anatomy.**—*First Class:* Francis James Stoward (Gold Medal), of Guy's Hospital.—*Second Class:* Leonard J. Miskin, of St. Thomas's Hospital.—*Third Class:* Robert Corie, of St. Mary's Hospital; Joseph S. Bolton, B.Sc., and George Bortram Hunt, of University College; and George Herbert Sowry, of St. Bartholomew's Hospital.

**Physiology and Histology.**—*First Class:* Forbes Fraser (Exhibition and Gold Medal), of St. Bartholomew's Hospital; Francis James Stoward (Gold Medal), of Guy's Hospital; Albert Ruskin Cook, B.Sc., of University of Cambridge.—*Second Class:* Harold Nolan, William Sampson Handley, and Alfred Salter, of Guy's Hospital; Edwin Josiah Toye, of St. Bartholomew's Hospital.—*Third Class:* Joseph Shaw Bolton, B. L. Abrahams, B.Sc., and H. J. Scharliob, of University College; Arthur Bousfield, B.Sc., of King's College.

**Organic Chemistry.**—*First Class:* Francis James Stoward (Exhibition and Gold Medal) and Harold Nolan, of Guy's Hospital; Arthur Bousfield, of King's College.—*Third Class:* Wm. Sampson Handley, of Guy's Hospital; Joseph Shaw Bolton, of University College; Edwin Josiah Toye, of St. Bartholomew's Hospital.

**Matéria Medica and Pharmaceutical Chemistry.**—*First Class:* Harold Nolan (Exhibition and Gold Medal), of Guy's Hospital; R. Smith Hardman, of Owens College and Manchester Royal Infirmary.—*Second Class:* Joseph Shaw Bolton, of University College; S. W. Brook, of Owens College.—*Third Class:* Edwin Josiah Toye, Forbes Fraser, and John Currie, of St. Bartholomew's Hospital; Richard J. Warrington, of Owens College; Richard Henry Norman, of Westminster Hospital; Thomas Albert Starkey, of University College.

**UNIVERSITY OF ABERDEEN.**—The following candidates received degrees in Medicine and Surgery on July 27th:—

**Degree of M.D.**—James M. Bett, M.B., C.M., Richmond, Victoria; John H. Brooks, M.B., C.M., London; Alfred Brown, M.A., M.B.; C.M., Manchester; Jas. F. Craig, M.A., M.B., C.M., Birmingham; Leslie Durno, M.B., C.M., Brechin; Alfred C. Ferguson, M.A., M.B., C.M., Thirsk, Yorkshire; James A. Macdonell, M.B., C.M., West Port, New Zealand; Wm. Milligan, M.B., C.M., Manchester; James P. Phillip, M.B., C.M., Morpeth; William S. Robertson, M.B., C.M., Port Said, Egypt. Graduated under old regulations: Frederick W. Robinson, M.B., C.M., Huddersfield; Alexander Simpson, M.A., M.B., C.M., Preston.

**Degrees of M.B. and C.M.**—Alex. S. Adams, Aberdeen; Alexander Anderson, M.A., Elgin; Wm. Boddie, M.A., Aberdeen; George G. Bothwell, Topsham, Devonshire; Riley Cunliffe, Acrrington; Charles M. Dawson, Rathen; Henry T. Dawson, Williamston, Insh; Robert Ferguson, M.A., Old Aberdeen; James Fraser, Ardersier; George Geddes, Portgordon; \*Jas. Gillespie, Aberdeen; Frank B. Graham, Manchester; Alfred Hogg, M.A., Laurencekirk; Alexander Innes, Auchnagatt; Walter S. Joss, M.A., Drumblade; Thomas B. Law, Aberdeen; Duncan A. McCombie, Aberdeen; James Marr, Tarves; Claude W. Marshall, Greenock; Thomas Massie, Torry, Udry; Arthur D. Milne, Fyvie; Chas. Mitchell, Aberdeen; Harry M. Mitchell, Castledearg, co. Tyrone; Duncan Neil, Aberdeen; Arthur W. Paterson, Aberdeen; William H. de Silva, Ceylon; William Sinclair, M.A., New Pittsigo; \*A. Tennyson Smith, Banff; James Sutherland, Newcastle-on-Tyne; \*John T. West, Dinnet.

\* Honourable distinction.

The John Murray Medal and Scholarship was awarded to William Troshwan.

**Diploma in Public Health.**—Jas. S. Cooper, M.B., C.M., Newmachar; William Thomson, M.B., C.M., Montrose; David M. Tomory, M.B., C. M., Constantinople (with credit).

**ROYAL COLLEGES OF PHYSICIANS AND SURGEONS IN IRELAND: CONJOINT SCHEME.**—The following candidates have passed the Fourth Professional (or Final) Examination, and obtained Licences in Medicine, Surgery and Midwifery:—Acheson Aiken, W. H. Best, W. Black, E. L. Camble, A. J. S. Cooper, C. F. D. Cowell, O. W. Elmer, J. K. Freyer, E. T. Good, E. W. A. Guinness, Giulio Hamilton, R. B. Hunt, W. S. Kane, H. G. P. Lofanu, J. P. Marnell, H. Moore, R. McCombe, V. E. J. McDonough, R. H. Olvor, J. M. O'Callaghan, S. J. C. Perry, J. M. Redington, Frederick O. Stoker, and J. Trumbull.

The following candidates passed in the subjects indicated:—

**Medicine.**—W. H. Anderson, C. R. Chichester, J. F. Elliott, H. G. Falkner, G. A. Fleming, Myles Jordan, W. H. Parr, N. J. Townsend, and F. Warren.

**Surgery.**—W. H. Anderson, H. G. Falkner, F. M. Golding, F. A. Madden, W. G. Posnett, N. J. Townsend, and F. Warren.

**Midwifery.**—C. R. Chichester, F. M. Golding, P. Peacocke, and S. W. Wilson.

**MEDICAL MAGISTRATES.**—Mr. John Moore, M.R.C.S., and Mr. William Japp Sinclair, M.D., have been placed on the Commission of the Peace for the City of Manchester.

WE understand that the cost of the splendid celebration of the recent Tercentenary of Trinity College was £10,000. The sum is large, but Tercentenaries do not occur every day, and the distinguished guests were gathered from all quarters.

**PRESENTATIONS.**—Dr. S. Clark of Blantyre House, Cullen, has been presented by his pupils of the ambulance classes with a case of surgical instruments.—On Saturday, the 6th inst., Dr. Burroughs of Crondall, Hampshire, was presented with a testimonial from friends and patients, consisting of an illuminated card with the sum of £126.

**HOSPITAL SATURDAY FUND.**—At a meeting of the Council of this fund, held at the central office on the 4th inst., the secretary (Mr. W. G. Bunn) reported the result of the recent ladies' street collection to be £5448 19s., being an increase upon last year of £506. The amount of the workshop collection was £5798, making a total of £11,246 19s.

**DR. WILLIAM GARDNER,** late Senior Surgeon to the Adelaide Hospital, and Lecturer on Surgery in the Adelaide Hospital Medical School, has, since his return from Europe, resigned his appointments in Adelaide. He has been elected President of the Surgical Section of the forthcoming Congress in Sydney.

**LADY ROBERTS' HOME ON THE HILLS FOR NURSING SISTERS.**—The annual statement regarding this institution in India gives a satisfactory account of the good work being done by these benefactors of the sick. Funds, however, are required in larger amount to make the endowment fund more adequate to the work designed to be accomplished.

**INGHAM INFIRMARY, SOUTH SHIELDS.**—At the annual meeting of the governors of this institution, held on the 10th inst., the report of the committee exhibited features which were not wholly satisfactory. For instance, the workmen's subscriptions for the past year suffered a diminution of £95 as compared with the sum received (£661 in 1891-92); whilst the number of subscribers and the amounts contributed at places of worship &c. have also diminished. It is satisfactory, however, to learn that whilst the income was somewhat less, the efficiency of the institution has been fully maintained.

## Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

**BAILEY, J. HAROLD, M.B., Ch.B. (Vlct.),** has been appointed House Surgeon to the Wirral Children's Hospital, Birkenhead, vice J. D. C. Allen.

**BELL, W. K., L.R.C.P. Lond., M.R.C.S.,** has been appointed Medical Officer for the Sheldon Sanitary District of the Newton Abbott Union.

**BRADBURY, J. A., M.R.C.S.,** has been appointed Medical Officer for the Wigan Sanitary District and the Workhouse of the Wigan Union, vice Martland, resigned.

**BRASH, E. A., L.R.C.P. Lond., M.R.C.S.,** has been appointed Medical Officer for the First Sanitary District of the Exeter Union.

**BRUCE, L. C., M.B. Edin.,** has been appointed Assistant Medical Officer to the Derby Borough Asylum, vice J. C. M. Given, resigned.

**CORNER, F., L.R.C.P. Lond., M.R.C.S.,** has been appointed Medical Superintendent for the Parish of Kensington.

**FIGGIS, S. BRADLEY, M.B., C.M. Edin.,** has been appointed House Surgeon to the Tottenham Hospital, vice Olaf Kloster, M.B., C.M., resigned.

**HEWAT, MATTHEW L., M.B., C.M. Edin.,** has been appointed Medical Officer of Health for Mowbray, Cape Colony.

**HOPKINS, G. HERNERT, M.R.C.S., L.R.C.P. Lond.,** has been appointed Honorary Medical Officer and Ophthalmic Surgeon to the Swansea and South Wales Institution for the Blind.

**HOWES, H. A., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg.**, has been appointed Medical Officer for the Hemingby Sanitary District of the Horncastle Union, vice Hadden, resigned.

**KAUFFMANN, O. J., M.D. Univ. Lond., M.R.C.P. Lond., M.R.C.S.**, has been appointed Physician to the Out-patient Department of the Queen's Hospital, Birmingham.

**KIRK, WILLIAM, M.D., M.Ch. Irel.**, has been appointed Fleet Surgeon to the Pel Yang Squadron of the Imperial Chinese Navy.

**LONGBOTTOM, WM., L.R.C.P., L.R.C.S. Edin.**, has been appointed Medical Officer for the Brightside Sanitary District of the Sheffield Union.

**MACALISTER, CHAS. J., M.B., C.M. Edin.**, has been appointed Honorary Physician to the Stanley Hospital, Liverpool.

**MACLENNAN, D. U., M.D., C.M. Edin.**, has been appointed Medical Officer for the North Widnes Sanitary District of the Prescott Union.

**MONK, H. G., M.R.C.S., D.P.H.**, has been appointed Medical Officer of Health for the Borough of Shrewsbury, vice Taylor.

**NEVBOLT, G. PALMENSTON, M.B. Durh., F.R.C.S. Eng.**, has been appointed Honorary Surgeon to the Stanley Hospital, Liverpool.

**PROSSER, FRANK, M.B., C.M. Glasg.**, has been appointed Medical Officer for the Rainford Sanitary District of the Prescott Union.

**REES, J. L., L.R.C.P. Lond., M.R.C.S.**, has been appointed Senior Resident Surgeon to the Royal Sea-bathing Infirmary for Scrofula, Margate, vice W. T. Rees, resigned.

**SIMMONS, HAROLD, M.R.C.S., L.S.A., L.R.C.P. Lond.**, has been appointed Assistant Medical Superintendent to the Fulham Infirmary, vice Dr. A. Scott, resigned.

**SMITH, E. N., M.B. Lond., L.R.C.P., M.R.C.S.**, has been appointed Assistant Medical Officer at the Infirmary, Fulham Union.

**SOMMERVILLE, JOHN, M.B., C.M. Edin.**, has been appointed House Surgeon to the Hospital, Auckland, New Zealand.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

**AMPTHILL UNION (RURAL SANITARY AUTHORITY), Ampthill.**—Medical Officer of Health for the District. Salary £52 10s. per annum. The appointment will be for one year.

**BOROUGH OF SUNDERLAND (PORT OF SUNDERLAND)**—Medical Officer of Health and Public Analyst. Salary £500 as Medical Officer for the Borough, £20 for the like office for the Port, and £5 as Public Analyst. (Apply to the Town Clerk; Town Hall, Sunderland.)

## Births, Marriages, and Deaths.

### BIRTHS.

**BLACKLER.**—On Aug. 3rd, at Kingsclere, Hants, the wife of H. J. Blackler, M.B., of a son.

**CORBIN.**—On Aug. 5th, at Morivale, Beckenham, Kent, the wife of E. R. St. Clair Corbin, M.B. Lond., M.R.C.S., of a daughter.

**HEFFERNAN.**—On Aug. 10th, at Barkston-gardens, S.W., the wife of J. J. Heffernan, Surgeon-Major, late Indian Army, of a son.

**MAC DONALD.**—On Aug. 7th, at the County Asylum, Dorchester, the wife of P. W. Mac Donald, M.D., of a daughter.

**PHILLIPS.**—On Aug. 2nd, at Grove-place, Falmouth, Cornwall, the wife of Arthur R. Phillips, L.D.S. R.C.S. Eng., of a daughter.

**SHILLINGFORD.**—On Aug. 5th, at Park House, Rye-lane, Peckham, the wife of Dr. H. Bartlett Shillingford, of a son.

### MARRIAGES.

**BRANFOOT—MALDEN.**—On Aug. 4th, at the Parish Church, Crowborough, Henry Seymour Branfoot, M.B., M.R.C.P. Lond., of Lansdowne-place, Brighton, to Emily Scott, eldest daughter of Henry C. Malden, M.A., of Windlesham House, Brighton.

**BURT—BARNES.**—On Aug. 4th, at Christchurch Priory, Hants, Robert Francis Burt, M.B., C.M., of Stroud-green-road, Finsbury-park, to Emma Jane, elder daughter of the late Rev. J. W. Barnes, M.A., Vicar of Kendal.

**CHEADLE—MANSELL.**—On Aug. 4th, at the Church of St. Matthias, Richmond, Surrey, W. B. Cheadle, M.D., F.R.C.P., of Portman-street, Portman-square, London, to Emily Mansell, eldest daughter of Robert S. Mansell, J.P., formerly of Rothbury, Northumberland.

**EVANS—DICKINSON.**—On Aug. 4th, at St. George's, Hanover-square, James William Evans, Surgeon-Major I.M.S., to Mary Florence, youngest daughter of William Howship Dickinson, M.D., of Chesterfield-street, Mayfair.

**FRANCIS—KING.**—On Aug. 4th, at St. Saviour's, Paddington, Louis Arthur Francis, M.R.C.S., L.R.C.P. Lond., youngest son of Fredk. J. Francis, Warwick-crescent, W., to Ethel, only daughter of the late H. King, of London and Manchester.

**GRAY—HENDERSON.**—On Aug. 3rd, at the Friends' Meeting House, Glasgow, Albert Alexander Gray, M.B., St. Alban's-place, Blackburn, to Mabel, youngest daughter of James Henderson, Glenval, Pollokshields.

**MORISON—MORISON.**—On Aug. 3rd, at the Parish Church, Broad-hempston, by the Rev. F. Townshend Chamberlain, Vicar of the Parish, Fred. Hughes Morison, M.B., C.M. Edin., D.P.H., of West Hartlepool, to Lizzie, second daughter of Capt. Morison, of Elm Park, Broadhempston.

**NEEDHAM—MONTGOMERY.**—On Aug. 10th, at the Parish Church of St. Mary, Carlisle, Joseph Needham, M.B., M.Ch., M.R.C.P., M.R.C.S., of Clapham-park, Surrey, to Alicia A. Montgomery, L.R.A.M., daughter of John Wilson Montgomery, M.R.I.A., Downpatrick, co. Down, Ireland.

**RISDON—CARSBURG.**—On Aug. 3rd, at Christ Church, Crouch End, by the Rev. C. W. Edmonstone, M.A., William Elliot Risdon, M.D., B.S. Lond., of Chancery-lane, to Pamela Maude (Daisy), only daughter of G. N. Carsberg, Esq., of Hornsey-lane, Highgate.

**RUSSELL—MICHELL.**—On July 28th, at Kenwyn Church, Truro, J. Rislen Russell, M.D., Queen Anne-street, W., second son of the late Hon. William Russell, of Elgin, Scotland, to Ada Gwenllian, fourth daughter of R. F. Michell, J.P., Glan Mor, Truro.

**SIMMONS—LEVI.**—On Aug. 4th, at Capetown, South Africa, Frederick Simmons, M.R.C.S., L.R.C.P., to Jennie, only daughter of the late Joseph Levi, of London.

**SMALLPEICE—PHILLIPS.**—On Aug. 9th, at St. Margaret's, Westminster, William Donald Smallpeice, L.R.C.P. Lond., of Queen Anne's-gate, Westminster, to Cicely, eldest daughter of the Rev. Sir J. Erasmus Phillips, Bart., Vicar of Warmistur.

**WOOD—RONALD.**—On June 22nd, at Christ Church, South Yarra, William Atkinson Wood, M.D., third son of the late Rev. Wm. Wood, of Hawthorn, to Janet Gardener, fourth daughter of Robert Bruce Ronald, of Pembury Grange, Kent, and Nap-Nap, New South Wales.

### DEATHS.

**BOOT.**—On Aug. 2nd, at Edinburgh, suddenly, Alfred Boot, Surgeon-Dentist, of Dunedin, New Zealand.

**CALLENDER.**—Between Aug. 1st and 4th, at Kimberley, South Africa, the result of an accident, Gerald Callender, M.R.C.S. Eng., L.R.C.P. Edin., Resident Medical Officer to the Kimberley Hospital, in the 82nd year of his age. (By cable.)

**COCK.**—On Aug. 1st, at Kingston-on-Thames, Edward Cock, J.P., F.R.C.S., aged 87.

**CREWE.**—On Aug. 4th, suddenly, at Rochester, William T. Crewe, F.R.C.S., L.R.C.P. Lond., of Nottingham, aged 38.

**CULLIMORE.**—On Aug. 7th, at the North-West London Hospital, Kentish Town-road, Daniel Henry Cullimore, Esq., M.D., of Welbeck-street, Cavendish-square. R.I.P.

**MACFARLANE.**—On Aug. 3rd, at Stoney-green Hall, Great Missenden, Alexander William Macfarlane, M.D., F.R.C.P. Edin., of 6, Manchester-square, W., aged 40.

REID.—On Aug. 5th, at Goldsmith-street, Nottingham, James Reid, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., aged 86.  
 WEBB.—On Aug. 3rd, at Mutley-park-terrace, Plymouth, Stephen Massett Webb, M.D., Surgeon-Major, A.M.D., and late of the 38th and 23rd Regiments, in the 64th year of his age.

*N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, August 15.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Tuesday, Wednesday, Friday, and Saturday at the same hour.  
 ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations daily at 10 A.M.  
 ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. and each day at the same hour.  
 CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30 P.M.  
 HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.  
 METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.  
 ROYAL ORTHOPEDIC HOSPITAL.—Operations, 2 P.M.  
 CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and each day in the week at the same hour.  
 UNIVERSITY COLLEGE HOSPITAL.—Ear and Throat Department, 9 A.M.; Thursday, 9 A.M.

Tuesday, August 16.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.; Fridays and Saturdays at the same hour.  
 GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.  
 ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.  
 ST. MARK'S HOSPITAL.—Operations, 2 P.M.  
 CANCER HOSPITAL, BROMPTON.—Operations, 2 P.M.; Saturday, 2 P.M.  
 WESTMINSTER HOSPITAL.—Operations, 2 P.M.  
 WEST LONDON HOSPITAL.—Operations, 2.30 P.M.  
 ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 2.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M. Throat Department, Tuesdays and Fridays, 1.30 P.M. Electrotherapeutics, same day, 2 P.M.

Wednesday, August 17.

NATIONAL ORTHOPEDIC HOSPITAL.—Operations, 10 A.M.  
 MIDDLESEX HOSPITAL.—Operations, 1.30 P.M.; Saturdays, 2 P.M. Ophthalmic Operations, Thursdays, 2 P.M.  
 CHARING-CROSS HOSPITAL.—Operations, 8 P.M., and on Thursday and Friday at the same hour.  
 ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.  
 LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.  
 ST. PETER'S HOSPITAL, COVENT-GARDEN.—Operations, 2 P.M.  
 SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.  
 GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 1.30 P.M.; Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.  
 ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.  
 CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9.30 A.M. Surgical Visits on Wednesday and Saturday at 9.15 A.M.

Thursday, August 18.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Surgical Consultations, Wednesday, 1.30 P.M. Ophthalmic Operations, Friday, 1.30 P.M.  
 UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Ear and Throat Department, 9 A.M.

Friday, August 19.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, August 20.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; and Skin Department, 9.15 A.M.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### THE STUDENTS' NUMBER.

WE beg to call the attention of the Deans of Medical Schools and the Secretaries of Hospitals to the announcement that the Students' Number of THE LANCET for the session 1892-93 will be published on Saturday, Sept. 3rd. We also invite from them and from the members of the profession information regarding hospitals, institutions for medical education &c.—such particulars as are of importance to students generally, both in connexion with the general medical qualifications, the dental qualifications, and the qualifications in public health. This should be sent to the Sub-editor, THE LANCET Office, Strand, not later than the 25th inst.

### SUICIDE ON ACCOUNT OF REJECTION AT AN EXAMINATION.]

THE increasing severity of the pass examinations of medical students in Italy multiplies the number of rejected candidates, some of whom have been found to put an end to their studies and even to their lives. A deplorable case of the latter "desertion of the post," as Plato puts it, is announced from the Bologna School. A student of medicine, known to be industrious and very popular with his class fellows, was found dead on the evening of the 6th inst. in his bedroom. He had committed suicide by severing with a razor the carotid artery of the left side. Failure to satisfy his examiners had, it seems, induced profound melancholia, under an acute accession of which he had thus made away with himself. There never yet, said Dr. Samuel Johnson, was a case of suicide which half an hour's well-inspired talk on the part of a friend and confidant might not have averted. Such opportune intervention appears to have been withheld from this poor student, whose fate ought surely to counsel a closer surveillance by the University authorities of their young charges, many of whom live in hired chambers, far from home and from the salutary corrective of that "sweet reasonableness" which family solicitude applies to the desponding or the disappointed in early life.

*Exhibitor.*—We sympathise with our correspondent in his complaint, which seems based on reason. But the matter complained of hardly comes within our province.

*Anxious.*—Our correspondent will most certainly be infringing the terms of the bond.

*Nemo* has not enclosed his card.

### FATAL CASE OF UNRELIEVED STRANGULATED HERNIA AT THE CAPE.

A CORRESPONDENT forwards us the following extract from the *Cape Argus* of June 8th:—

"One of the most painful and saddest of cases that has happened in the district of Tarka occurred on Saturday last to Mr. Enslin of Rictoley, a married and family man, thirty years of age. The circumstances are as follows:—On Saturday, May 22nd, he was working with a waggon, when on Sunday a serious rupture took place. A messenger was at once sent to Tarkastad for medical assistance, which could not be procured. On Tuesday, the poor fellow being in distressing agony, a medical man was again sent for to Tarkastad, but with the same result. On Wednesday the complaint took a more aggravated form; the patient became worse, and, to use the words of one who visited the house, 'It was heartrending to hear the poor man's cries for a doctor.' A messenger was for the third time despatched to Tarkastad for a medical man, only to be greeted as on the two former occasions. On Thursday, the patient being in such intense pain, the family, as a last resource, sent to Adelaide for the necessary medical attention. On Friday, 27th, at 11 A.M., this poor fellow passed away, having for the previous twenty-four hours suffered beyond description, the last few only being delirious, leaving a wife and family of three children utterly unprovided for, simply for the want in the first instance of a few moments' medical skill."

Ozæna should consult his usual medical adviser. We do not recommend practitioners.

Messrs. Harold Smith and Gorrings.—The correspondence is closed.

### "MEDICAL AID ASSOCIATIONS."

To the Editors of THE LANCET.

SIRS,—This agitation against men who accept medical aid associations' appointments is, of course, the work of the general practitioners. But, as "Verax" points out in your issue of July 30th, they are themselves alone to blame. And how, I should like to know, does the officer of a medical aid association offend more against "medical ethics" than he who accepts a Government colonial appointment at even smaller pay and has to go to the ends of the earth to earn it? Both alike are guilty of accepting inadequate remuneration from paymasters who can afford to pay better. So is the assistant, though he cannot help himself, poor fellow! So is the parish doctor, and so are nine-tenths of the medical officers of health, if it comes to that. But the general practitioner does not propose to boycott these. What they do does not affect his pocket, and therefore he does not consider that they offend against medical ethics, or, if they do, it is "no business of his." For the average general practitioner seems to hold the saving faith that medical ethics exist only for his protection and advantage and for nobody else's. He does not consider it at all improper for him to take 10s. 6d. or 15s. for a confinement or 1s. 6d. for a visit, if thereby he can undersell his neighbour. That is not "degrading the profession," or "creating the impression in the mind of the public that medical services are worth little or nothing"; but he considers it beyond all expression wicked and horrible that any man should dare to undersell him. Of course, there are very many honourable men to whom such a description does not apply. At all events, the men who pay their assistants fairly, and treat them honourably, and recognise them as "brethren" are very few. Of the truth of this any impartial man can convince himself by simply watching your advertisement columns for a week or two. I say nothing of the men who make a practice of employing unqualified assistants. Their claws, no doubt, will soon be cut by drastic legislation.

If general practitioners recognise the indisputable fact that medical aid associations are surely ruining general practice in towns, let them band themselves together to render it impossible for these societies to obtain skilled medical aid at an unfair rate, not by still further oppressing the unhappy assistant class, but by themselves paying their assistants fairly and treating them honourably.

It is perhaps well for me to add that I am not a medical aid association's officer, and that though I have been an assistant I am now, I thank heaven, one no longer. I am, in fact,

Your obedient servant,

August, 1892.

A GENERAL PRACTITIONER.

### A POMORPHINE.

To the Editors of THE LANCET.

SIRS,—The question is sometimes asked, How long will a solution of apomorphine keep? I have some by me that was prepared ten years ago. It is dark-green in colour, but as efficacious as ever. Its strength is one-twentieth of a grain of the alkaloid in five minims. On the 28th of last month I was called to a man who had swallowed an ounce of tincture of opium about an hour before he was found at 1.30 P.M. I at once injected five minims of the solution into the right arm, and in less than three minutes free vomiting took place. The man recovered. Age apparently does not affect the potency of this useful drug.

I am, Sirs, yours faithfully,

Peterborough, Aug. 5th, 1892.

W. EASBY, M.D.

PROPOSED DISCIPLINARY POWERS OF THE MEDICAL COUNCIL  
OF NEW SOUTH WALES.

*Mr. H. M. Doyle* is thanked for his letter. We quite perceive the force of our correspondent's representations. We are still of opinion that it is essential in a profession to enforce a high ethical standard of manners and conduct, and to regard many things as wrong which the common law does not condemn, and we should be sorry to admit that what is found good in the mother country is impracticable in her colonies. At any rate, members of British colleges might be expected to uphold their traditions. It is, of course, vital to this theory that the Medical Council itself should be composed of men of exemplary conduct and honourable position. This will not be obtained by lowering the standards, but by raising them and by bringing the best professional opinion and influence to bear on the elections to the Council.

*L. A. S.*—Professor Mosso's brilliant lecture on the Physical Education of Woman, on which we commented shortly after its delivery in Rome before the Queen of Italy, is now published in a revised and convenient form under the title of "Sulla Educazione Fisica di Donna" by Messrs. Treves of Milan.

THE ETHICAL ASPECT OF AGREEMENTS TO SERVE  
MEDICAL AID ASSOCIATIONS.

To the Editors of THE LANCET.

SIRS,—In answer to your request for fuller information I beg to state that the association with which I am connected charges a small entrance fee, and before any person is admitted each applicant has to present himself or herself to me, and as I find their state of health and age I classify them into three separate degrees—the first, those in good health and of reasonable age; the second, those aged but in good health, and those who require a little attention; the third, those in absolutely bad health or ailing at the time they present themselves. Some cases of persons in bad health I refuse altogether, and they, if they still wish me to attend, have to pay under dispensary rules and fees. Class 1 pay 5s. per year and entrance fees; class 2, 10s. 6d.; class 3, £1 1s. Children in proportion, so that we have one family of five persons paying about four guineas per year. There is no wage limit, but I exercise my discretion, and I will undertake to say we have no one in the association whose wages exceed £2 per week or a few shillings over (the wages in the railway works here being paid to the best workman by piece work, so that they vary from week to week). The fees in the dispensary are comparable to those procured by the majority of practitioners in the poorer districts of London. I was in practice there for several years, and I am not speaking from hearsay. Of course it is disagreeable to work for a committee, and it requires backbone to withstand their efforts to put matters on a very queer basis; but I submit that it concerns the person holding the appointment solely and wholly. It is not true that the whole profession here are dead against the association; the leading practitioner, Dr. —, meets me if I desire a consultation, and is friendly. Again, my predecessors, with the exception of the last gentleman before my time, were certainly not desirable personages, and had I been in private practice I should have shunned them myself. But why the sins of my predecessors should be visited on me I cannot say. Much as I should desire the dignity of my profession to be kept up I cannot see that I am lowering it by attending poor persons for a given sum; it is medical insurance for the poor to the core. I conduct my duties with as much decorum, attention and skill as in me lies; of course the insurance attracts the poor, and doubtless it touches the pockets of my professional brethren here, but I submit in these days that is an argument that will not stand. The discrepancy amongst private practitioners in their charges sets aside the fee question. The misdeeds of my fellow men are no excuse, I know, for any misconduct on my part, but no unqualified assistant here is ever allowed to prescribe for any patient; but an unqualified assistant of one of the "scoffers" did visiting throughout the winter and spring. Our agreements may be hard on us, but many of us are anxiously waiting for you, who have such a large circulation in our profession and so much influence, to put the pros and cons before the many. I do not think the members of the medical calling understand the position thoroughly, and if you will only point out the abuses and the virtues plainly we, through a society we are now forming, solely consisting of members of the profession attached to friendly societies, can point to our committees an authoritative statement of the abuses, and I undertake to say that I for one can get them remedied where I am placed. It is hardly up to the dignity of our profession to form a "trade union," as a correspondent has suggested in your columns. The matter must be faced as long as members do not "trade," and so long as reasonable precautions are taken that people who can pay dispensary fees do so. So long as I conduct my profession fairly and do not poach other men's patients, and uphold, as I am enjoined by my agreement with my college, the dignity and honour of my profession, wherein do I err? Does the dignity of my profession consist in charging high fees which the poor cannot afford and then putting them in the county court?

I remain, Sirs, your obedient servant,

August, 1892.

H

MEDICAL ADVERTISING IN SYDNEY.

Two very bad specimens are sent us in newspaper slips from Sydney—one in which "Dr. A. Paterson, A.M., M.D., C.M., F.R.C.S. Ed., and M.R.C.S. Eng." boasts that "no medical man advertising in these colonies has medical degrees which can be compared with his," and ends by offering to send for 2s. 6d. his book on the male generative organs &c.—In the other, by "Dr. M. Perry, M.R.C.S. and L.S.A.," a permanent and complete cure is suggested of everything, from nervous weakness to tumours and diabetes.

W.—The subject is treated in another column of our present issue.

WORKERS IN CO-OPERATIVE STORES.

To the Editors of THE LANCET.

SIRS,—I should be glad to have the experience of your readers as to bad health and mortality amongst stores workers. My own practice shows that the rate in one of London's chief establishments (I believe the largest) is enormous, notwithstanding the fact that all workers are, before entering service, medically passed, and after entering are tended by doctors specially retained. Certain of them (patients of mine) confirm my experience without suggestion from me, and say that in the stores it is commonly remarked, "The stores are killing their men." They attribute it to (1) overcrowded rooms; (2) work underground, gas, and general stuffiness; (3) chills on leaving the buildings. They dare not complain, because the situations are well paid and the hours good. Certainly these men are not of the order of grumblers and only lament loss of health as necessary to existence. As the stores show large profits, surely public opinion or public authority should compel them to provide more room, ventilation, and electric light, as well as medical help. Could a return be got, I believe their sickness and mortality rate would be startling. To get some such return is the object of this letter.

Aug. 2nd, 1892.

I am, Sirs, yours faithfully,

CANTAB.

"BIRTH OF A CHILD WEIGHING FOURTEEN POUNDS."

To the Editors of THE LANCET.

SIRS,—Having read with interest in THE LANCET of July 30th (p. 250) the account of a labour case given by Dr. Harris in which an infant weighing over 14lb. was born alive, I beg to say that a similar case occurred in my practice last week. The presentation was a breech, and the appearance of the patient's abdomen led me at first to conclude it was a case of twins. By abdominal palpation I came to the conclusion it was not, but an infant of excessive size. Labour was very tedious, and I procured the assistance of my friend Mr. Duke, and by our united efforts we succeeded in delivering the patient of a very large infant, of which I give the measurements from my note-book:—Weight, 14lb. 2oz.; chest measurement, 16½ in.; arm circumference, 5½ in.; thigh circumference, 8 in.; length, 25 in. The infant was asphyxiated when born, but Mr. Duke, by his plan of producing artificial respiration, succeeded in a very short time in fully resuscitating the infant.

I am, Sirs, yours faithfully,

Rathmines, Dublin, Aug. 2nd, 1892.

ALEXANDER GORDON.

ACUTE SPINAL MENINGITIS.

To the Editors of THE LANCET.

SIRS,—The following case of acute spinal meningitis which came under my notice a few months ago may be of interest to your readers. I was called to a young man suffering from trismus and slight pain in the lumbar region which were not due to any local disease or injury. Within a few days acute spinal meningitis set in and ran a severe course for seven days without any improvement, although the usual remedies had been prescribed. On the eighth day I gave antipyrin in 5 gr. doses every two hours for twenty-four hours. The patient experienced slight relief after the first dose and continued to improve rapidly to perfect convalescence. I should be glad if any of my fellow practitioners who have used antipyrin in the treatment of acute spinal meningitis would give their experiences of its effects.

I am, Sirs, yours faithfully,

Aberystwith, Aug. 9th, 1892.

G. R. E. BONSALL.

TREATMENT OF CARBUNCLE.

To the Editors of THE LANCET.

SIRS,—Whether the use of Listerian methods is common in treating gangrene, carbuncle &c. as well as abscesses I do not know. I have, however, had a case of large carbuncle in which the careful use of the perchloride solution and sal alombroth gauze has, after a free crucial incision, greatly expedited the cure. On the eighth day I had to deal with a granulating wound, the sloughs having rapidly softened and discharged and the dressings being repeated daily. The skin flaps were then drawn into close apposition, except at the centre of incisions, where there was a deficiency of the size of a threepenny piece, and the wound healed at once. *Bis curat qui citò curat.*

I am, Sirs, yours faithfully,

Aug. 9th, 1892.

ANTHRAX.

## Clinical Lecture

ON A CASE OF

HEAD INJURY FOLLOWED BY HEMIPLEGIA  
AND DILATED PUPIL,

Delivered at St. Mary's Hospital on March 5th, 1892,

By HERBERT W. PAGE, M.A., M.C. CANTAB.,  
SURGEON TO THE HOSPITAL.

GENTLEMEN,—I will ask you in half an hour to go over with me to the post-mortem room that we may look inside the head of a man who died yesterday and whose case presented several symptoms of unusual interest. I am glad of the opportunity of talking to you about it before the necropsy is made. We shall be able to consider the case unfettered by any knowledge of what has been already found, and shall be free from the temptation of fitting our diagnosis to the revelations of the post-mortem room. That is a very easy and comfortable procedure, and I shall adopt the much more profitable course of telling you what were the arguments which led us to the conclusion that in this particular instance no good was likely to follow a resort to surgical measures. In every case of severe head injury that comes before him the surgeon has to ask himself whether by any operation that he can do he may save the patient's life. That question was forcibly put to us by the symptoms of this patient, whose head will presently be opened, and whose case has provided a good example of those sorts of problems and difficulties which seek for a solution in most cases of cranial injury. I will briefly describe the case. I will tell you what I believe to have been the lesions. I will ask you to weigh over again with me the arguments which occurred to us at the bedside, and we will then go and find out the mistakes we made as to matters of fact, of conjecture and of conclusion.

The patient, fifty years of age, was admitted at five on the afternoon of the 2nd March, half an hour after he had been thrown from the box-seat of a hearse, the horses of which had bolted. The man had been thrown violently on his head, and the abrasion and swelling and closure of the right lids told that he had alighted on the right fronto-temporal region of his skull. He had bled slightly from the nose. No fracture of any kind was to be felt, and there was no wound of the scalp. He was unconscious, deeply so, but by no means to the fullest extent; shouting at him evidently produced an impression, although no answer came, and when the hairs of his beard were pulled he resented the insult, raised his arms, comforted his face and slightly groaned. I was under the impression at the time that he was rather more inclined to move his left arm than his right, but there was no other indication of one-sided palsy. There was no facial paralysis, and the pupils were equal. That from the manner of his fall and the character of his symptoms the man had probably met with some serious brain injury there could hardly be any doubt, but so soon after the accident it was manifestly impossible to say how much of his unconsciousness might be due to concussion alone. Clearly at that time there was nothing whatever to call for the use of the trephine; there was no fracture or depression, no evidence that hæmorrhage in any quantity or in any reachable place was going on inside the skull. Late in the evening my house surgeon, Mr. Low, sent for me, and I saw the patient again at eleven, seven hours and a half after the accident. We failed to discover any change in his mental condition, and the pulse and respiration were the same as upon his admission, 70 and 18 respectively. Two symptoms, however, of vast importance and interest had now become developed—viz., undoubted right hemiplegia, leg, arm and right half of face being all paralysed; his arm dropped helpless when it was raised, differing altogether from the behaviour of the left arm; and the left angle of his mouth was decidedly drawn, whilst his right cheek and lips remained placid and expressionless. Further, there was dilatation and immobility of the right pupil, the left being small as it had been at first, and naturally responsive to the stimulus of light.

Let us consider these various symptoms separately and collectively and then I will tell you why, in spite of them, I

No. 3599.

was induced not to trephine. Remember that the man had fallen on the right side of his head, and that he now had right hemiplegia. The degree of the paralysis affecting the face as well as the limbs made it practically certain that there was a lesion somewhere in the opposite left hemisphere. What might the lesion be? Either extensive laceration and contusion of brain from *contrecoup*—a thing in the circumstances by no means improbable—or hæmorrhage upon the surface of the brain or at some place within its substance. Now we argued that even if a *contrecoup* surface lesion were the cause of the right hemiplegia, no operation that one could do would be of the smallest use in remedying the condition. To expose and remove the bruised part of a brain could really be of no practical good whatever. Was hæmorrhage, however, the lesion, and might we hope to remove a large clot, to the pressure of which the symptom hemiplegia was due? I answered No, because I felt sure that if the hemiplegia were due to a surface and reachable extravasation, such extravasation must of necessity be large—large enough to do something more than produce the considerable degree of hemiplegia we found, to cause general indications of brain compression as well. Like other organs of the body the brain is unable to perform its various functions, unless it be properly supplied with blood. A compressed brain, however, is a bloodless brain, blood cannot find the needful room to circulate through it, and after death you will find it pale and with its blood squeezed out of it; and so the symptoms of brain compression are those of annihilated function; mental processes are impossible, and coma becomes profound, the pulse and respiration become increasingly slow and laboured, the breathing is stertorous, all vital processes are put an end to, and death ensues. Our patient showed none of these conditions; he was certainly not more, he was perhaps rather less, comatose than on admission, and his pulse and respiration were not altered in the least. He ought, in my opinion, to have shown some more decided evidence of his brain being compressed, and I could not believe that his hemiplegia was the result of a hæmorrhage such as could be got at through a hole made with the trephine. I feared rather that there was hæmorrhage in some unreachable place in the centre of the hemisphere. Had there been a superficial widely distributed extravasation of blood in the so-called subarachnoid space, I thought it highly probable there would have been some sign of surface irritation in twitching of the right limbs and face rather than the decisive hemiplegia which we saw. Taking all these facts into consideration I definitely gave up any idea of using the trephine on the left side of the man's head. We had, however, still to do with a symptom of not less importance than the one I have named. This was the dilatation of the right pupil, and we had to consider whether that was a fact of such significance as to warrant operative interference at any other part of the head. I daresay you know that in cases of hæmorrhage from the middle meningeal artery dilatation of the pupil on the side of the hæmorrhage is a symptom which may be of much value in diagnosis. Mr. Hutchinson was, I believe, the first to call especial attention to it, and Mr. Jacobson, who has written an exhaustive monograph on this variety of intracranial hæmorrhage, even speaks of it as "Hutchinson's pupil." How is this dilatation brought about? By supposed gravitation and extension of the blood-clot, which, of course, lies between the dura mater and the bone, to the base of the skull, so as to interfere, by direct pressure upon it, with the function of the third nerve.<sup>1</sup> In some of the recorded cases a widely dilated pupil on the same side as the hæmorrhage has been a marked phenomenon. It was very necessary, therefore, to apply our knowledge of this fact to our own patient. The blow had been received, as you remember, on his skull at that part which I have spoken of as the right fronto-temporal region, not so very far from the place where the middle meningeal artery lies in contact with the anterior inferior angle of the parietal bone, and it is by no means impossible that the vessel may have been ruptured here, even though no fracture of the bone was to be felt. In one at least of the recorded cases of middle meningeal hæmorrhage the vessel had given way at the site of a fissure fracture—a mere crack in the parietal bone, which was quite undiscoverable from the outside. I was met, however, with this great objection to the likelihood of middle meningeal hæmorrhage having occurred in our patient by the entire absence of those general symptoms or

<sup>1</sup> On this point, however, the reader will do well to consult a recent paper by Dr. Dear on Cerebro-spinal Pressure: Journal of Pathology, No. 1, p. 51.

compression which had already made us conclude that his right hemiplegia was not the resultant symptom of any gross hæmorrhage on the opposite surface of the brain. It seemed to me a most unlikely thing that a hæmorrhage of such extent as to gravitate and extend to the base of the cranium and there cause pressure on a nerve should have failed to cause indications of compression of the whole brain, and so produce the symptoms of which I spoke a few moments ago. In all the cases where this dilatation of the pupil has been met with on the same side as a middle meningeal hæmorrhage the hæmorrhage has I believe been large and the coma has been increasingly profound. The symptoms have indeed been of such urgency that trephining was imperatively called for to rescue the patients from impending death. Our patient showed no such indications, and I came to the conclusion that his dilated pupil was due either to some small basal hæmorrhage, or, more probably, to a direct injury of the nerve in a fracture of the base of the skull running from before backwards and passing in the immediate neighbourhood of the clinoid processes where the third nerve lies. I felt therefore that no good whatever was likely to accrue from a trephine hole being made over the site of the middle meningeal artery, and we resolved to leave the man alone. Here let me interpolate a word as to fractures of the base. Commonly transverse in one or other of the fossæ a fracture may sometimes be found which runs from before backwards, all depending on the mode in which the injury has been inflicted. A fracture of the base is not in itself of much moment; its only importance lies in the fact that a basal fracture cannot well occur without grave concomitant injury to the brain. This it is which makes such cases frequently fatal. Could you succeed in fracturing a base without brain injury the fracture need not cause you more concern than fracture of the tibia or fibula.

The progress of our patient's case presented no new features of importance. The hemiplegia and the pupil remained the same, while the unconsciousness decidedly was less, during the whole of the next day (Thursday, the 3rd); and it was not until the morning of the 4th that his respiration became embarrassed, either because of pulmonary engorgement or because of concussion effects on the medulla. He died at mid-day, forty-four hours after the accident. These, then, were the facts of his case, and I hope it will not be without advantage to you to have tried with me once again to solve the problems which, like so many head cases, it presented. We may have been wrong in refraining from operation, but although trephining is not in itself dangerous one ought to have good reason for resorting to it, and not even appear to trephine for trephining's sake. I doubt in this particular case if anyone could have said where exactly he ought to have trephined had the question been put to him. I put it to myself and could not answer it, and I believe I had the full agreement of Mr. Low in what we did and refrained from doing. Before I end let me, then, say what I think it probable we shall find when the man's head has been opened. Contusion of the brain immediately beneath the site of the blow on the skull; contusion, and possibly severe laceration from *contrecoup* in the opposite left hemisphere; some inconsiderable hæmorrhage upon the surface and in the neighbourhood of this contusion, but more probably a larger intra-cerebral hæmorrhage which has destroyed some part near the corpus striatum and the great motor tract on the left side; some small hæmorrhages at the base of the cranium, not from the middle meningeal artery, which may have interfered with the third nerve, but more probable than this I think will be the existence of a basal fracture running from before backwards and directly injuring that nerve in the neighbourhood of the clinoid processes. Now let us go and see whether we were right or wrong in not using the trephine, even though we were in face of two such prominent facts as homiplegia and a dilated pupil.

*Abstract from notes of necropsy by Mr. J. J. Clarke.*—Abrasion over the right frontal eminence, with ecchymosis on both sides of the cranial aponeurosis corresponding to the abraded region. The pericranium separated more easily than usual over the frontal region. No fracture was to be seen at any part of the exposed calvarium. The dura mater was throughout abnormally adherent to the bone. Over the posterior parts of the occipital lobes there was a small amount of blood free beneath the arachnoid. In the anterior, middle and posterior fossæ of the right side of the skull there were a number of small clots, and in the posterior fossa a considerable quantity, say 2 oz., of liquid blood. When the dura mater had been removed from the base a fissure

fracture was discovered which started from near the external angular process of the frontal bone (right), crossed the right orbital plate, the right optic foramen and the anterior border of the sphenoidal fissure at its inner end, and detached the anterior clinoid process. The right third nerve was torn (?) in removing the dura mater, and its precise condition was therefore undetermined. No gross lesion was seen in the optic nerve. In the frontal lobes of both hemispheres—in that of the right more especially—there were numerous small areas of hæmorrhagic softening bruises, but there was no evidence of contusion from *contrecoup* in the occipital lobes. In the middle of the left internal capsule there was a hæmorrhage the size of a horse bean. There was no blood in the ventricles.

These notes speak for themselves, and the only point to which I would especially refer is the internal capsule hæmorrhage. Here was a hæmorrhage such as is commonly seen quite independent of injury in the usual place and with the usual symptoms. The brain was not bruised to any degree at this spot; it was not, indeed, the spot where it was likely to be affected by *contrecoup*, and *contrecoup* lesions were markedly absent just where they had been expected. It seems probable therefore that the man had a diseased vessel at the time of the accident, and that the violence of the concussion caused it to give way. In favour of this view is the fact that the man looked much older than his years, that his kidneys were undoubtedly cirrhotic, and that there was atheromatous thickening of his aortic valves.

## Clinical Lecture

ON THE

### DIFFICULTIES AND DANGERS WHICH MAY ARISE FROM INDISCRIMINATE ATTEMPTS AT THE REDUCTION OF STRANGULATED HERNIAE BY MANIPULATION.

*Delivered in St. George's Hospital Medical School,*

By WILLIAM H. BENNETT, F.R.C.S. ENG.,  
SURGEON TO THE HOSPITAL.

GENTLEMEN,—It is, I assume, a matter of common knowledge that many methods of treatment in themselves excellent, and when properly used of much practical utility, may under certain conditions be not only harmful but perhaps disastrous, especially if applied without discretion by any person who does not possess the knowledge or skill requisite for their safe employment. The means available for the reduction of a strangulated hernia without operation form no exception to this rule, and by an unusual chance there are now under my care two patients lying in the Harris ward, separated from each other by a single bed only, whose cases illustrate this fact in a remarkable way.

CASE 1. *Strangulated inguinal hernia; prolonged unsuccessful taxis; herniotomy; gut found partially lacerated; suture of bowel; radical cure; recovery.*—W. F., a man aged twenty-seven, was admitted on Nov. 18th. 1891. In the previous April he found for the first time that he was ruptured on the right side. The hernia was always reducible, and a truss was continually worn. On the morning of the day before the patient came into the hospital the spring of the truss broke and he was therefore obliged to work without it. The hernia soon came down, and he was unable to reduce it. Vomiting thereupon set in, and during the night occurred many times. A few hours before his admission an attempt, lasting about a quarter of an hour, was made to reduce the hernia by manipulation, but without success, the patient suffering great pain, especially during the latter part of the attempt. The bowels acted regularly up to the morning of the 16th. On admission the man had an anxious look and was evidently in very acute pain. There was occasional retching, by which a small quantity of sour-smelling gastric contents was brought up. The tongue was white, but moist; the pulse 100 and fairly full. In the right side of the scrotum and running up to the groin was a large, acutely painful and tender swelling, very tense, resonant and entirely without impulse. There was much

gain about the umbilical region and also some tenderness over the hypogastrum, but no distension. Having regard to the prolonged taxis to which the hernia had been already subjected, no further attempt at reduction by manipulation was made, herniotomy being at once performed. Upon opening the sac several ounces of reddish fluid, containing air, escaped. A large knuckle of greatly distended gut then came into view, deeply congested and gently glued to the lower part of the sac by very recent peritonitis. On freely exposing this gut, by laying open the sac from end to end, there was found over its most prominent part (i.e., at the anterior aspect of its lower end) a longitudinal laceration involving the peritoneum for about an inch; over half its length this rent passed through the subjacent muscular coat, from the opening in which the mucous membrane protruded, and seemed on the point of bursting. The stricture, which was at the inner ring and extremely tight, was then very freely divided with the hope that the tension in the gut would be thus sufficiently modified to allow of the wound in the bowel walls being sutured. This, however, was found to be impracticable, as the stitches immediately cut their way out, the tension not being sufficiently relieved spontaneously. It was at the same time clear that any attempt to reduce the tension by pressing the air contained in the bowel back into the abdomen would result in the rupture of the protruding mucous membrane, which I was particularly anxious to avoid for reasons to be presently discussed. I therefore selected the healthiest available spot on the bowel, and there punctured it with an exploring trocar, afterwards emptying the knuckle of gut of the contents, which consisted principally of altered blood, through the cannula. This having been done the gut naturally collapsed. The wound in its walls was then brought together with perfect ease and safety by means of five Lembert sutures of silk. A single suture of the same kind having been passed across the small peritoneal wound made by the trocar, the bowel was finally thoroughly cleansed and returned into the abdomen. The neck of the sac was then isolated, ligatured, and severed from the scrotal portion; the pillars of the ring were closed by kangaroo tendon sutures, a drainage-tube inserted, and the superficial wound united with silkworm gut. On the 20th four loose motions containing altered blood were passed. The bowels acted daily after this, and by Dec. 18th the patient was walking about the ward apparently in perfect health. In fact, he was practically well by Dec. 4th, but being very apprehensive about himself he was allowed to remain in bed longer than was really necessary. In addition to the points specially relating to the main subject of the present lecture, this case affords a good illustration of the successful treatment of cases of the kind by a method to which I wish to call particular attention. In all instances of strangulated hernia in which the laceration of the bowel does not involve the whole thickness of its walls, so that the intestinal canal is not opened up, the gut as the result of the strangulation is of course greatly distended. In attempting to bring together the edges of the wound under these circumstances difficulty generally arises in consequence of the sutures cutting their way so readily through the peritoneum, that sufficient traction cannot be made upon them to effect the closure of the laceration with any safety. This tendency on the part of the stitches to cut their way out is due partly to the unyielding tension of the bowel and partly to the softening of its coats from pathological changes. Not only therefore is very little pressure required under such circumstances to increase the rent in the peritoneum, but when the tear involves the whole thickness of the muscular coat the mucous membrane bulges through the wound, and extremely slight force only is necessary to cause the protruding portion to give way, thus converting an incomplete laceration into a wound opening up the intestinal canal.

In cases of this sort it is sometimes also found that even after free division of the stricture no sufficient alteration in the tension occurs until digital pressure is used, which may be quite sufficient to burst the stretched and protruding mucous membrane—an accident which it is most important to avoid if possible, not only because it must of necessity allow the bowel contents to escape over the wound, but also because the protruding membrane is usually so thin and injured that if it is damaged further by laceration, incision or puncture, ulceration, and perhaps sloughing, is prone to occur later on, and give rise to trouble which may possibly be serious. In order to diminish the tension of the bowel and to allow of its shrinking of its own accord and without any necessity for inflicting further injury upon the protruding

mucous membrane, I adopt and confidently recommend the following plan, which, it will be noticed, was used in this case.

The stricture having been freely divided, and the distended knuckle of gut carefully cleansed, an exploring trocar is passed into the bowel through the portion of its walls which appears most healthy (i.e., at a point which is certain to be somewhat remote from the laceration). The contents of the gut, consisting generally for the most part of altered blood, pass out easily through the cannula into a suitable receptacle, and are thus conducted quite away from the peritoneum, which therefore remains entirely unsoiled, as the muscular coat at the point of puncture clings so closely to the cannula that no leakage takes place. On the other hand, if the puncture be made in the protruding mucous membrane, leakage is certain, and soiling of the whole rent occurs, in addition to the injury inflicted by the puncture on the damaged structures. The collapse of the gut which follows spontaneously makes the approximation of the peritoneal surface over the laceration perfectly easy and safe, no matter how softened the intestinal walls may be. The gut may then be returned without hesitation, after it has been finally cleansed and a single Lembert suture placed across the little nick in the peritoneum at the seat of the puncture. This last detail is perhaps hardly necessary, but it is a source of additional safety during the return of the bowel, and adds nothing material to the length of the operation. The method here described of relieving tension in damaged or partially lacerated bowel by puncture through the healthier parts rather than through those which are most injured has, so far as I know, not been previously insisted upon but I am sure it is worthy of adoption.

CASE 2. *Inguinal hernia with large hydrocele; attempted reduction by patient; rupture of wall of hydrocele, which was thus converted into a hamatocele.*—W. B.—, a labourer aged fifty-three, was admitted into Harris ward on Nov. 21st, 1891, with the following history. Three years previously he commenced wearing a truss, as he was told he had a rupture; and about eighteen months later he noticed some swelling of the scrotum which, upon applying to the Truss Society, he was told was not a hernia. On the day before he came to the hospital he felt some pain about the groin and noticed more swelling there than he had previously seen. Thereupon, thinking it was the hernia which had come down, he attempted to put it back by seizing the whole scrotal tumour in his hands and using considerable force. No immediate alteration was produced in the swelling, but acute pain followed directly, and in a few hours the whole scrotum became almost black. The pain gradually decreased, but much tenderness followed, on account of which he applied for treatment. On admission the patient was a big, strong-looking man. The left side of the scrotum was much discoloured and distended by an oval swelling, very tense, tender, and non-translucent. Its upper end was quite free from the abdominal ring, which was large, and through it a hernia came down when the patient coughed. The bruising slowly disappeared, and the swelling decreased a little in size after rest in bed. On Dec. 17th I laid open the scrotal tumour, letting out a quantity of hydrocele fluid and altered blood. On examining the walls of the cyst there was found at the upper and inner part a large rent, admitting the ends of three fingers, which passed into a considerable space beneath the scrotal integuments. The parts about this were matted together with recent inflammatory material and the walls of the hamatocele were covered with new lymph. The hernia was not exposed in the operation, as it was thought wiser, considering the inflamed condition of the tissues, to postpone its radical cure, which the patient was anxious to have performed, until a subsequent date. The patient naturally made an uninterrupted recovery.

The main point of individual interest in this case is the fact that the injury was self-inflicted. Although the lesion produced here by the patient's manipulation was not a serious one it may sometimes be so. I have myself had an opportunity of seeing an instance in which taxis applied by the patient resulted in a small rent in the gut through which some fecal material had escaped into the sac. It is true that the gut at the seat of injury had obviously been adherent and the laceration had resulted from the tearing away of the adhesion by the force applied; the fact, however, is significant that laceration of the bowel itself was produced by no more violent manipulation than that applied by the patient himself, who was perfectly accustomed to reduce his rupture.

The main possible disasters which may immediately follow upon attempts at the reduction of herniæ by taxis may be summarised as follows:—(1) Bruising of the bowel; (2) rup-

ture of the bowel walls, complete and incomplete; (3) laceration of adhesions; (4) rupture of the sac; (5) hæmatocele (in cases complicated with hydrocele); (6) Hæmatoma of scrotum and surrounding parts; (7) reduction of the whole hernia with the sac (reduction *en bloc*).

1. *Bruising of the bowel.*—Some bruising, as shown by sub-peritoneal extravasation, of large or small extent, about the herniated bowel will be found in the majority of cases which have been submitted to taxis unless extreme gentleness only has been used. The extent and severity will naturally depend, for the most part, upon the amount and direction of the force applied and to a considerable degree upon the condition of the gut, which bruises more readily when greatly distended, especially in neglected cases which have been allowed to continue for a long period without treatment. It is interesting to note that bruising of the bowel, if in any way extensive, although without any apparent breach of surface on the peritoneal aspect, is almost invariably associated with bleeding into the intestinal canal, a fact conclusively demonstrated in many cases by the characteristic appearances of the first motion passed after the relief of the stricture, which nearly always contains altered blood. It may, in fact, be accepted without reserve that attempts at reduction by manipulation produce some bruising of the bowel in the great majority of cases of strangulated hernia. At the same time it may be fairly admitted that as a rule, unless great carelessness has been used, no permanent harm results. It is nevertheless necessary to insist on the occurrence of injury of the kind in order to give weight to the fact that attempts at reduction by manipulation are liable at times to cause injury. Taxis therefore should not be regarded, as it seems to be by some people, as a plan of treatment which if it fails to reduce the rupture, at least can do no harm. This last remark must not be taken to imply any objection to the proper practice of this method, but merely as a warning against its use carelessly and without due regard to possible evils which may under certain conditions result.

2. *Laceration of the bowel.*—This may of course involve the whole thickness of the intestinal wall or only one or more of its coats; the former is naturally the most serious since it allows of the escape of feces into the sac. The latter condition may vary in degree from an almost imperceptible crack in the peritoneum to a laceration in the peritoneal and muscular coats inches in length, in which case the mucous coat protrudes, hernia-like, through the opening in the muscular wall. Whether the laceration is partial or complete the treatment is identical. The edges of the wound must be brought together with Lembert sutures, care being taken that the end stitches—if the lesion is of any extent—are placed a short distance beyond the extremities of the rent. When the gut is too tense to allow of approximation of the peritoneal surfaces it should, if necessary, be emptied in the way I have described in the first of the cases which form the text of this lecture. However small the crack in the peritoneum is, even if it be hardly perceptible to the eye, a single suture should be passed across it. If the condition of the patient in cases of partial laceration is so desperate that the delay entailed by the suturing process is not justifiable the gut should be cleansed and returned into the abdomen, an unperforated drainage tube of large calibre being left lying in the canal in the way I have recommended in a lecture published in THE LANCET in 1890.

A point of great interest to which sufficient attention has not, I think, of late been paid arises here with reference to the situation at which laceration from injury occurs in these cases. There appears to be an idea, which is traditional and supported by the teaching of the schools now, that the tear produced by injury in the gut of a strangulated hernia takes place *at the seat of stricture* in consequence of the way in which the sharp edges of the constricting tissues, as it were, cut into the distended bowel when pressure is exerted upon it.

Now I have seen several cases myself in which a rent in the gut was undoubtedly produced by taxis, and in two of these the lesion was *not at the point of constriction but on the prominent bulging and most distended portion of the bowel*. Both of these cases were recent, and in each the rent was in the long axis of the gut. The same result followed in some experiments made by me on the cadaver, artificial strangulation in two cases of old hernia having been produced by inflating the bowel from the abdomen and forming a stricture by ligaturing the neck of the sac together with its contents. The hernia was in one instance then violently crushed and in the other struck sharply with a stick; in both the laceration occurred

on the prominent part of the strangulated knuckle and in the long axis of the gut. On consideration, this result, so far as the situation of the injury is concerned, is, I think, precisely what should be expected in recent cases, for in such the rent begins in the peritoneum, which under pressure naturally gives way at the weakest point (that is to say, where it is most thinned and stretched by distension). A sudden blow, therefore, or prolonged hard pressure would as a matter of course lacerate the peritoneum in the part most stretched and thin—i.e., over the end of the distended knuckle rather than at the seat of constriction, where not only is it unstretched, but where it is actually supported by the surrounding parts.

In cases far advanced and neglected the state of affairs is altogether different, because in them the gut at the seat of stricture is indented by the edge of the constricting tissues, partially eaten through by ulceration from within, or perhaps gangrenous and on the point of giving way. Then the weakest point is at the strictured part, and very little force may be necessary to complete the perforation which has already commenced. It is, I presume, in connexion with cases of this latter kind that the traditional teaching has been fostered, for in recent cases of strangulation it certainly does not apply.

3. *Rupture of adhesions in the sac.*—The tearing of recent adhesions during attempts at reduction by manipulation need not have any serious result, but free hæmorrhage into the sac may thus be produced so as to fill it completely with blood, although no serious lesion may be apparent. In old irreducible hernie, in which band-like adhesions sometimes exist between the bowel and the sac wall or between different parts of the bowel itself, no harmful results need follow if the adhesions themselves give way, but if, as may happen, an adhesion brings away some of the intestinal peritoneum with it, a partial laceration of the gut results, which is, if at all extensive, a serious condition, especially if the case has been neglected and operation long deferred.

4. *Rupture of the sac.*—This, although a recognised injury and classed as one of the modifications of the reduction *en masse*, must be a very rare sequence of taxis, as the amount of force required to tear the sac is very great and would hardly be intentionally applied. Bruising of the sac is, however, common and I have seen a portion of its wall torn away with an omental adhesion; this, however, is not a rupture in the sense under discussion—i.e., a splitting of the sac wall from sudden or gradual pressure. In the post-mortem room I have not been able in artificially strangulated hernia to rupture the sac without also bursting the gut. Rupture of the sac is therefore probably too rare to be other than a curiosity; indeed Sir Astley Cooper, after his large experience, says that it “scarcely ever” occurs from any cause. Formerly spontaneous rupture of the sac was also a recognised condition, but actual evidence of its existence seems wanting, or at all events is not convincing.

5. *Hæmatocele.*—A good example of this accident is afforded by Case 2, described in this lecture. After what I have said concerning the difficulty in causing rupture of a hernial sac it may at first sight seem strange that the sac of a hydrocele should give way so easily. There is nothing inconsistent, however, in this, for it must be borne in mind that the sacs of hydrocele sometimes undergo pathological changes which result in softening and thinning, so that they become weak in parts.

6. *Hæmatoma from rupture of a large vein or veins outside the sac.*—Enormous blood extravasation may be thus produced and occasionally upon the application of comparatively slight force, especially in elderly people. I once had an opportunity of seeing a large blood swelling involving the scrotum and groin, which were nearly black from discoloration, said to have followed upon nothing more violent than the manipulation necessary for the adjustment of a truss to an easily reducible hernia in a subject nearly eighty years old.

7. *Reduction “en bloc”*—i.e., the reduction of the sac, together with its contents, the strangulation being therefore unrelieved.—The only point to which I need here call attention in this respect is the singularly small amount of force which sometimes seems necessary to produce this accident. I have personally seen only one case, and that was not in my own practice. The hernial tumour seemed to disappear almost the moment the hand was laid upon it and certainly before there was time for the application of any methodical violence. So much was this the fact that I cannot help feeling that there must be in such a case some kind of spontaneous action from

above which contributes to the reduction. Is it possible that extreme irregular spasmodic attempts at peristalsis may act in this way?

It is only fitting that such an ominous list of casualties, which are not only possible, but actually occur in practice as the result of the use of taxis, should be followed by some indication as to when and how the reduction of an irreducible hernia by manipulation may be attempted without risk. The relative safety of this plan of treatment is dependent on three conditions. (1) The manner in which the taxis is applied; (2) the period during which the manipulation is persisted in; and (3) the state of the hernia.

1. *The mode of applying taxis.*—This may appear such a purely elementary point as to render its consideration hardly justifiable outside the pages of a student's text book. It is nevertheless true that practitioners, otherwise intelligent and trustworthy, do at times manipulate a hernia in the manner best calculated to cause injury to the contents of the sac, whilst it affords the least possible chance of effecting reduction. I do not propose to occupy time now with a description of the method by which the taxis may be applied safely and with a fair prospect of success, as it can be more usefully learnt from practical demonstration at the bedside, but some of the details of the process are so important and essential that they require a passing notice. The details referred to are as follows: (α) All manipulations should be conducted only with thoroughly warm hands; (β) the neck of the hernia should be firmly supported by one hand whilst the other manipulates the body of the tumour. (γ) In using the fingers all pressure from the finger-ends should be made by *the front of the digital pad and never by the actual tips*. (δ) The pressure necessary in the manipulations should be gentle, firm and regular, not forcible, unsteady and spasmodic. The necessity for warm hands, for the support afforded to the neck of the hernia, and for the avoidance of the use of the actual finger tips, is, I cannot help feeling, not so universally acknowledged as it certainly should be, for I have more than once seen attempts made at the reduction of a rupture by grasping the body of the tumour with hands almost blue with cold, the neck of the hernia being left entirely unsupported, and then with a punching and rolling movement, during which the finger tips have been deeply pressed into the parts, the force has been gradually increased until further persistence in the attempt has been rendered impracticable by the protests of the patient. Where injury is possible it is from some such faulty plan as this that it is most likely to result. The cold hands excite every resistance in the way of muscular action; the want of support to the neck of the hernia makes its reduction very unlikely by allowing the gut to bulge over the margins of the constricting ring, and, beyond this, in neglected or long-standing cases, when the bowel has commenced to ulcerate from within, the pressure of the sharp edges of the stricture acts at a great advantage in further injuring and perhaps bursting the thinned and weakened intestinal walls. Finally the sharply indenting finger tips are admirably adapted for causing an unnecessary amount of bruising and possibly laceration of the gut.

2. *The time which should be occupied in taxis.*—Judging from my own experience, and from what I have seen in the practice of others, five minutes should be taken as the outside limit during which manipulation of a hernia in cases of apparent strangulation or when impulse on coughing is absent may be with safety persisted in, no matter how gently it is applied. In unstrangulated cases the same time should always be considered as sufficient, for, although no actual harm need result, if the time be extended it may very easily produce it; moreover, if success is not attained by the end of five minutes it is very unlikely to result at all, and further attempts are practically useless.

3. *The condition of the hernia.*—When properly applied and with the precautions just mentioned taxis may be used with safety—(a) in all cases in which the true hernial impulse is present, provided always that there is neither any marked tenderness nor inflammation in the sac or its contents, when its employment would of course be entirely negated; (b) in very recent cases of strangulation where the tension is not extreme. This latter is a recognised principle and is therefore worthy of respect, but I very much doubt whether it is possible, excepting perhaps in infants, to reduce by manipulation any rupture in which the hernial impulse is not present. For myself at least I must admit that I have never been able to return with any reasonable application of

force a hernia in which I could detect no impulse. This impulse, it is true may have sometimes been slight, but it was present all the same in the cases where reduction was possible, although it must be admitted that I could not always demonstrate it to my house surgeons in the hospital patients. A large distended hernia universally resonant should be treated with more than usual gentleness, for in such cases the bowel is far more liable to injury than in any other kind, especially if adhesions happen to exist in the sac. Hernial tumours dull on percussion, with omental or fluid contents, may be manipulated with greater freedom without much risk of damage being done, but in these reduction is entirely out of the question in the absence of impulse, the utility therefore of persistence in the attempt at all under these circumstances is not plain. Every case of apparently strangulated hernia must necessarily be treated upon its individual merits, but, for my own part, I am sure that, as a general principle, it is better in herniæ which are obviously strangulated and entirely without impulse to perform herniotomy at once rather than make attempts at reduction by manipulation, because I have no doubt whatever that early herniotomy in fairly competent hands is infinitely less hazardous than an unwise persistence in fruitless attempts at reduction by taxis. If due regard be paid to the patient's welfare, one thing at least is certain—viz., that a strangulated hernia which has once been subjected to taxis should be operated upon at once, and no further manipulation used until after the tumour has been explored and the stricture freely divided.

It must not be imagined that all risk of lacerating the bowel during attempts at its reduction necessarily ends after the sac has been laid open in herniotomy, or indeed in every case after the stricture has been divided, for, although to the best of my knowledge the accident has not occurred under these circumstances in my practice, I have been present at an operation in which a surgeon of experience certainly did produce a laceration in the peritoneal coat of the bowel, whilst attempting to reduce it after the division of the stricture which obviously gave rise to the strangulation. This difficulty sometimes experienced in reducing the hernia after the stricture has been cut is undoubtedly as often as not due to the division being not sufficiently free, the little nick so commonly recommended being too slight for securing the necessary relaxation of the constricting band. I am sure, from my own observation that harm is more often likely to arise from too slight a division of the stricture than from one which is too free. Free division of the parts about the neck of the hernia as a rule entirely obviates any chance of injury to the gut, whilst the possible anatomical dangers entailed in this free incision have been, I have no hesitation in saying, unduly exaggerated.

Although I make a practice of dividing the stricture freely, I have never had the slightest cause to regret it, and certainly have never seen any hæmorrhage which has given the least anxiety under these circumstances. The only case in which I have had any trouble whatever on account of bleeding after herniotomy was a strangulated umbilical hernia, in which alarming hæmorrhage took place into the abdominal cavity from a torn omental vein. This vessel was almost certainly burst by the force which was necessary for the return of the hernia through a ring which had been only slightly divided; had the division been altogether more free the hernia could have been reduced without any force and the vessel would, I believe, have undoubtedly remained intact.

I now come to a point which is especially interesting in connexion with a further difficulty which occasionally arises in the reduction of a hernia, even after the stricture has been freely divided. At first sight it is a singular fact that any difficulty should occur at all under these conditions, still it is quite certain that it is sometimes met with. For instance, in a case of inguinal hernia under my own care I was unable, after repeated division of the stricture, to reduce the intestine, although on passing the finger, as is my habit, through the canal into the abdominal cavity, I could feel nothing in any way constricting the bowel. The only noticeable thing to be felt was a loose membranous fold which, springing from the outer wall of the canal, lay quite flaccid upon the gut, and allowed my finger to pass by it with perfect ease. Whilst I was attempting to return the bowel, the end of one finger being placed on it just below this fold, I noticed that as the gut was pushed against the flaccid flap the latter seemed to grip the bowel after the manner of a sling. I therefore divided the fold, and then returned the hernia without the least trouble. Here, then,

the obstacle to reduction was clearly this loose sling-like fold. The existence of membranous flaps like this and the manner in which they sometimes resist the return of the gut in operation for strangulated hernia have not of late received the attention they merit. Bands and flaps of this kind, which are not very rare, should invariably be divided whether they seem to compress the bowel or not, for if they do not actually prevent reduction it will be much more easily effected after their division. The history and mode of formation of these interesting folds may be conveniently reserved for consideration in another lecture.

### A CASE OF CEREBRO-SPINAL FEVER FOLLOWED BY RECOVERY.

By WM. ARMSTRONG, L.R.C.P., L.R.C.S. EDIN., L.S.A.

I WAS called shortly after 6 A.M. on May 11th to see A. B—, aged eleven years, who had been suddenly seized with intense pain in the head. The history of the case is as follows. On May 9th the patient was apparently well, and played football in a hot sun. After returning home he complained of feeling tired, and shortly after vomited bilious matter; he was hot and feverish. His mother, thinking he was bilious, administered a purgative draught. During the next day he remained in much the same condition, but on the following morning at 6 A.M. he was suddenly roused by a loud blast from a hooter, and at once complained of intense pain in the head, and became very restless and excited. I could obtain no history whatever of pain or discharge from either ear. On my seeing the patient he presented the following appearance. He lay on his back with his head on one side, the lower limbs being flexed on the abdomen. The face was flushed, conjunctivæ injected, pupils unequal, dilated, and sluggish, with great intolerance of light. Temperature 103·8°, pulse 120, very excited. On examining the chest, the heart was seen beating violently with a forcible impulse. The abdomen was rather retracted; no tenderness or pain on pressure; no tympanites. No other abdominal symptoms. Slight diarrhoea, which was probably due to the purgative which had been administered. Tongue very furred in the centre and red at the edges. The patient kept crying out "Oh, dear!" in a very distressed way, and did not seem to understand questions put to him. He said that the worst pain was over the temples. He vomited green matter whilst I was there. By way of treatment, I ordered the head to be shaved and an ice-bag applied and prescribed three grains of calomel and a mixture containing five-grain doses of bromide of potassium, the diet to be milk with soda-water or lime-water. During the first week the temperature ranged between 101° and 104° and the pulse between 108 and 120. The headache was much the same, but considerably relieved after each dose of medicine. The patient complained of pain in the back of the neck, down the spine, in the arms and at the pit of the stomach. The position he assumed was one of partial flexion; the head was thrown well back and there was marked stiffness of the neck. There was also marked hyperæsthesia all over the body. The tongue remained very furred; bowels rather constipated; there was no enlargement of the spleen. He continued very restless and delirious, at times being in a condition of stupor. There was great intolerance of light; sluggish pupils with strabismus of the left eye. A large quantity of pale urine was passed. The lower lobes of both lungs became congested. During the second week the patient improved a little and took nourishment well. There was now marked retraction of the abdomen. As he passed very wakeful restless nights I prescribed a draught containing fifteen grains of bromide of potassium and five grains of chloral hydrate with success. Temperature about 102°. At the end of the third week the temperature fell to normal; pulse 80; bowels constipated; there was a good deal of pain in the hips, down the spine, in each leg and also in the neck; a small mustard poultice placed behind the ear relieved the latter; general condition improving; diplopia and strabismus occasionally present. On May 30th the patient became very much worse. Temperature 104·8°; pulse 120. Herpes round the mouth, with sordes on the teeth and tongue; the latter was very dirty looking. He vomited, complained of his head, and lay in a stupor. As an error in diet was traced I ordered a tablespoonful of castor-oil, and on June 1st he was much

better, with a normal temperature. After this the improvement continued. The appetite was very good. He occasionally complained of frontal headache, but there were no other pains. The intolerance of light gradually lessened, but diplopia of the left eye was present until June 8th. Ordered to have a farinaceous diet with a little fish.—June 10th: Patient very much improved; convalescence rapidly advanced.—July 9th: Went away to the seaside, apparently quite well.

*Remarks.*—The patient is said to have lost a sister aged four years of acute meningitis, death taking place in twenty-six hours; the supposed cause was a chill. There is no tubercular history on either side of the family. During the whole of the present attack careful examination failed to detect any sign of pulmonary tuberculosis. The patient is an intelligent, precocious lad, very fond of books. Last December, whilst on a visit at Congleton, he had an attack of illness, in which the following symptoms were present: frontal headache, vomiting, constipation, fever, with loss of appetite for seven days. The case was diagnosed by the medical man as "slow fever." With respect to the term of "diplopia of the left eye" used in the description of the case, the following are the facts. When the left eye was closed vision was normal; when the right eye was closed the patient said he saw two doctors or two mothers with the left eye.

Pontesbury, Salop.

### THE CONDITION OF TWENTY-FOUR CASES OF EMPYEMA IN CHILDREN AFTER CURE BY RESECTION OF RIB.

By E. B. HASTINGS, M.D. LOND.,

LATE RESIDENT MEDICAL OFFICER TO THE EAST LONDON HOSPITAL  
FOR CHILDREN, SHADWELL;

AND

HARFORD N. EDWARDS, M.R.C.S., L.R.C.P. LOND.,  
LATE HOUSE PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN,  
SHADWELL.

THE operation of resection of a portion of a rib, with free drainage of the pleural cavity, is one now generally performed in empyema after other treatment has failed; but the ultimate results of the operation as regards deformity, &c., are not well known, because the patients are not, as a rule, kept under observation after the wound has healed, although there are still abnormal physical signs in all cases. With the view of ascertaining what is the condition of cases of empyema in children after a considerable period has elapsed from the date of discharge from hospital, we have examined as many old patients of the East London Hospital for Children as were accessible. All the patients in the hospital books for the last eight years have been written for, but the great majority having changed their residences since leaving the hospital the letters addressed to them have been returned undelivered. In a few other cases no notice was taken, although the letters were apparently delivered. We have been able to examine 24 cases, all of whom had had a portion of one rib excised, and notes of their present condition are given below. The following figures show the periods which have elapsed since the operations were performed: Seven years in 2 cases, four to five in 4 cases, three to four in 2 cases, two to three in 7 cases, one to two in 6 cases, and less than one year in 3 cases. The ages of the patients at the time of operation were as follows:—One year in 2 cases, two years in 6 cases, three in 2 cases, four in 3 cases, five in 3 cases, six in 3 cases, seven in 1 case, eight in 1 case, nine in 2 cases, thirteen in 1 case.

The causation of the empyema is in most of our cases doubtful, the patients having been brought to the hospital only when the disease had reached a more or less chronic stage; but it is stated to have been the result of pleuro-pneumonia in some of them, and it was probably a sequela of this disease in most cases. It is difficult to obtain an accurate account of symptoms, as most of the children are too young to give a statement of their own symptoms, and their mothers are either unobservant or, being at work all day, ignorant of them. It is impossible to get an account of the symptoms without putting leading questions, and the description of them must therefore be taken with some reserve. There was pain in the affected side in two cases, but only occasionally. In eight there was a history of cough, but in only one was it stated that the cough was severe.

Four of these eight cases had slight bronchitis when examined, and another had granular pharyngitis, to which the cough was probably due. Two of the eight were said also to suffer from shortness of breath. One child was stated to be wasting. In her case the wound continued to discharge for nearly two years; the child had scarlet fever during this time, and the physical signs now suggest dilatation of bronchi. (*Vide* Case 24, A. T.—.)

Coming now to the more certain ground of physical examination, we find that the results are better than the account given by the mothers would have led us to expect; the completeness of the recovery in the great majority of cases has indeed surprised us. The general nutrition was good in 19 cases, and fair in 5. Not one of them looked wasted or ill. In the majority of the cases inspection of the chest gave no indication of disease beyond the presence of the scar. The spine was straight in 19 cases, slightly curved in 3, and distinctly curved in the remaining 2. In 15 patients the shoulders were on the same level; in 7 the shoulder on the side on which the empyema had been was slightly lower, and in 2 the shoulder was distinctly lower. In no case was there distinct and obvious flattening of the chest wall; in 16 there was complete absence of flattening, and in the remaining 8 there was a slight degree of flattening. The gap made in the rib by the operation appeared to be closed with bone in all. No difference could be made out between the movements of the two sides in 14 cases; in 8 the expansion was slightly less on the diseased side, and in 2 there was a distinct deficiency of movement. The results from percussion were as follows: Complete absence of dullness was found in 8 cases; in 7 there was some dullness in the immediate neighbourhood of the scar, no doubt due to the inflammatory thickening and increased rigidity of the parts there; in 5 there was slight dullness over a more extensive area; and in the remaining 4 there was distinct dullness. The breath sounds were unaltered in character and equal on the two sides in 10 cases; in 2 they were rather weaker in the situation of the scar; in 10 there was weakness of breath sounds over a considerable area of the diseased side as compared with the breath sounds on the healthy side, the difference being only slight in 3 cases; in the remaining 2 the breath sounds were distinctly weak on the affected side. In only one case did we find any adventitious sounds limited to the affected side, and in this case only at the end of a deep inspiration; but four patients had slight general bronchitis when examined. The position of the heart's apex beat was noted in twenty of the cases equally divided between the right and left empyemata. It was found to be close to the left nipple line in 17 cases. In 2 cases of left empyema the apex beat was one inch and three-quarters of an inch respectively outside the left nipple line, probably from imperfect re-expansion of the left lung. In 1 case of right empyema the apex beat was three-quarters of an inch to the left of the left nipple line, presumably the result of adhesions formed before the pleura was drained, for imperfect re-expansion of the right lung would cause the position of the heart to be moved to the right. The altered position of the heart's apex and the scar left by the operation were the only abnormal physical signs that we could discover in the last-mentioned case. In 2 cases the impulse was noted to be in the fourth intercostal space, in 15 it was in the fifth interspace; in some the position could not be defined. The lowest and most external point at which the heart's pulsation could be felt has been taken as the position of the apex beat. The result points to good recovery of the lung in nearly all the cases. The completeness of the recovery is very surprising when we consider how severely ill a child generally is before operation, how profuse is the discharge of pus after operation, and to what an extent the physical signs are altered even when the wound has healed. When discharged from hospital deformity and impaired movement of the chest and dullness and weakness of breath sounds are generally quite distinct; but in the majority of our cases these physical signs of disease have become either very slight or quite absent with the lapse of time—in no fewer than seven the presence of the scar, with a slight alteration in the percussion note in its immediate neighbourhood, being the only remaining evidence of the disease. In many cases the healthy appearance of the children was very striking, especially when it is considered under what unfavourable hygienic conditions the poor of the East-end of London, who constitute the bulk of our cases, live; and hardly any of them could be described as unhealthy looking. In only one case were there any signs suggestive of

phthisis, and in this case the signs were not sufficient to warrant more than a suspicion of that disease, while the general condition of the patient was decidedly opposed to it. We did not discover any evidence of lardaceous disease, but the urine was examined in only a few cases. There was no œdema in any case. To save repetition we give full notes of only 3 cases, which may each be taken as a type of a group, although the divisions between the groups are not very sharply defined. The case of A. T.—stands by itself as the least satisfactory of all. The terms "slight" and "slightly" are several times used in this paper. They have been applied only to conditions in which the alteration from the normal or the difference between the physical signs on the two sides was so little that careful examination was required to detect it, and that in ordinary clinical work it would hardly have been noticed.

*Case 1.*—W. C.—, aged two years, admitted May 11th, 1889, with a history of three weeks' illness. Causation of empyema doubtful. A history of phthisis on mother's side. There were signs of a pleural effusion on the left side. May 14th, chest aspirated, and eight ounces of pus withdrawn. On May 17th the chest was opened, a portion of a rib being resected and the pleura drained. The patient left the hospital on June 4th. Condition on May 15th, 1891, two years after the operation:—Occasional cough, but not short of breath, and able to run well. He holds himself erect as he walks. Appetite good; well nourished. The spine is straight, and the shoulders are on the same level. Chest of good shape; no flattening. Movements equal on the two sides. Percussion note everywhere equal on the two sides, except in the neighbourhood of the scar, where it is slightly higher pitched. Breath sounds equally good on both sides; no adventitious sounds. Apices of lungs normal. Cardiac impulse felt in fifth space as far as a quarter of an inch outside the left nipple line. Liver felt just below the edge of the ribs; spleen not felt; fingers not clubbed; no œdema.

The following 6 cases closely resemble the above, and only the points in which they differ from it will be mentioned:—

*Case 2.*—W. W.—, aged two years and eight months at time of operation. Examined sixteen months later. Chest rather barrel shaped; liver felt three fingers' breadth below the ribs.

*Case 3.*—P. B.—, aged three years and six months at time of operation. Examined two years afterwards.

*Case 4.*—G. B.—, aged seven years at time of operation. Examined four years and nine months afterwards. History of occasional pain in right side passing to umbilical region.

*Case 5.*—L. A.—, aged eight years at date of operation. Examined seven years later.

*Case 6.*—J. J.—, aged nine years at time of operation. Examined seven years later.

*Case 7.*—J. A.—, aged two years and six months at time of operation. Examined three years and nine months later. Said to have pain occasionally and frequent cough.

In the following 13 cases the recovery is not quite so perfect, all showing either slight deformity, dullness, or weakness of breath sounds.

*Case 8.*—H. J.—, aged three years when admitted on Feb. 13th, 1888, with signs of pleural effusion on the left side. "Very scrofulous-looking, with clubbed fingers." Feb. 17th: A part of seventh rib in posterior axillary line excised, and about six ounces of thick greenish pus removed.—April 29th: "Discharged with contraction of left side." Examined three years afterwards, and the following note made:—The mother says that the wound did not heal until two months after leaving the hospital, but child well now in every way. Looks very well; face a good colour; fingers not clubbed; no œdema. Spine a little curved, with convexity to the left in the dorsal region. Shoulders and scapulae on the same level on the two sides. Some very slight flattening at the left anterior axillary base. Movements of chest equal on both sides behind, in front rather better on the right side. At extreme left base and near the scar the percussion note is very slightly higher pitched, with rather weak breath sounds; Elsewhere percussion note and breath sounds perfectly good. Apices normal. Cardiac impulse felt out as far as a quarter of an inch to the left of the left nipple line. Systolic murmur at apex. Liver and spleen not felt.

The following 12 cases resemble Case 8 and, as before, only the differences will be mentioned:—

*Case 9.*—A. E.—, aged two years when admitted for operation. Examined four years and a half later. Systolic murmur at apex, probably hæmic; no flattening of chest.

*Case 10.*—B. F.—, aged eight years when admitted for

operation. Examined nearly five years later. At right apex in front bronchial breathing and slight increase of vocal resonance; general condition very good; no flattening of chest walls.

*Case 11.*—A. M—, aged two years when admitted for operation. Wound continued to discharge for eight months according to mother. Examined two years later. Heart normal.

*Case 12.*—S. W—, aged two years when admitted for operation. Examined nearly two years later. Considerable prominence in left mammary region, but spine nearly straight; movements and percussion note the same on the two sides; heart normal.

*Case 13.*—C. A—, aged nine years when admitted for operation. Examined six months afterwards. No flattening of chest. Heart normal.

*Case 14.*—J. B—, aged seven years when admitted for operation. Examined ten months afterwards. No flattening of chest. Heart normal.

*Case 15.*—W. S—, aged four years and six months when admitted for operation. Examined seven months afterwards. No flattening of chest. Heart normal.

*Case 16.*—R. H—, aged two years when admitted for operation. Examined seven months later. Heart normal.

*Case 17.*—F. T—, aged six years when admitted for operation. Examined one year and nine months later. A few small râles are heard at the left base at the end of a deep inspiration. Heart normal.

*Case 18.*—A. P—, aged two years and six months when admitted for operation. Examined four years and three months later. No dulness. Liver three fingers' breadth below edge of ribs. Heart normal.

*Case 19.*—A. H—, aged five years and six months when admitted for operation. Examined eleven months later. Cough troublesome. Has enlarged tonsils and granular pharyngitis, which probably explain the cough. No flattening of chest. Heart normal.

*Case 20.*—C. D—, aged six years when admitted for operation. Examined one year and six months later. Said to be in better health than before illness. Front of chest rather flat. Small râles at both bases. Heart normal.

In the three cases which form the next group the permanent alteration in the physical signs is rather greater, although the general condition is good in all.

*Case 21.*—F. C—, aged thirteen years, was admitted on Nov. 5th, 1888, with a history of pain in the right side for two months, and signs of a pleural effusion on the right side. No family history of phthisis. On Nov. 12th aspiration was done and six ounces of straw-coloured fluid drawn off. On Dec. 17th twenty-seven ounces of pus were withdrawn. On Jan. 4th, 1889, the chest was opened, a portion of the seventh rib being resected at the angle of the scapula. On Feb. 12th the patient was sent to a convalescent home; there was still a fair amount of pus discharging from the wound. In June, 1890, the wound was still discharging, but, after scraping the sinus and removing a piece of necrosed bone from one of the cut ends of rib, it healed; it had been discharging about eighteen months. The patient in May, 1891, about two years and four months after operation, looked very well. Nutrition good. No cough, pain or dyspnoea. Hands and feet always cold, but said to have been the same before the illness; fingers not clubbed. Slight convexity of dorsal spine to left. Right scapula and shoulder rather lower than left. Respiratory movements better on left side than on right. Veins slightly dilated on right side. Slight flattening on right front. Percussion note dull, with increase of resistance, at right base from level of scar downwards; diminished resonance in right axilla; the same on the two sides in other situations. Breath sounds weaker over dull area and over whole right front. No adventitious sounds. Heart's apex in fifth space just internal to nipple line. No murmur.

*Case 22.*—M. B—, aged six years at the time of operation. Examined two years and three months afterwards. Spine straight; slight tendency to pigeon breast; some general bronchitis. In other respects the physical signs are much the same as in Case 22.

*Case 23.*—R. R—, aged seven years, when admitted for operation. Examined two years and six months later. Spine straight. Very slight flattening at right front. Dulness at extreme posterior base on right side with weak breath sounds; dulness at right axillary base, with weak breath sounds and prolonged expiration. Systolic murmur at apex and base of heart, probably hæmic.

*Case 24.*—A. T—, aged four years at time of operation. She had scarlet fever shortly after leaving the hospital, and the wound did not heal for about two years. Examined two years and nine months after operation. Coughs a great deal and brings up a large quantity of phlegm; no hæmoptysis, but sometimes epistaxis. Breath very short, and patient cannot walk fast. Losing flesh. General nutrition very fair. Spine straight. A little flattening at left anterior axillary base. Left shoulder rather lower than right. Movement of left side of chest a good deal diminished. At the left base the resonance is diminished and resistance increased from angle of scapula downwards; at extreme base quite dull. Respiration weak all over the left base, with râles. In the axilla the breath sounds are weak and bronchial, almost tubular; apices normal. Cardiac impulse in fifth space half an inch outside left nipple line; double thrill felt at apex; double murmur, loudest at apex, but heard all over the left side of the chest. No history of rheumatism or chorea could be obtained. Spleen one finger's breadth and liver two fingers' breadth below edge of ribs. No œdema. Fingers rather clubbed.

## PSYCHO-THERAPEUTICS.

A SCIENTIFIC FRAGMENT.

BY WM. DALE, M.D. LOND.

"As the state of the mind is capable of producing a disease another state of it may effect a cure" (John Hunter). In this article I wish to consider, imperfectly though it must be, these questions—(1) The influence of the mind on the body in producing diseases; but especially (2) the influence of the mind in curing or removing diseases. The subject is doubtless beset by difficulties, among which perhaps the most formidable are, first, that we are obliged to depend for information on the subjective feelings of the sufferers themselves; secondly, on the often very garbled and misleading statements made respecting these feelings. The gist of our subject is contained in these lines of Churchill:—

"The safest way to health, say what you will,  
Is never to suppose we shall be ill;  
Most of those ills we poor mortals know  
From doctors and imagination flow."

The influence of the mind on the body is well burlesqued in the following story. Sir T. Moore being visited by Erasmus, the former endeavoured to convert him to a belief of the real presence in the Eucharist, and assured him that if he would *only believe* he would be satisfied of its truth by unquestionable evidence. On leaving Moore's home he borrowed his pony, and finding it useful did not incline to return it, but sent certain Latin stanzas as under:

"Quod mihi dixisti,  
De corpore Christi,  
Crede quod edis, et edis;  
Sic tibi rescribo  
De tuo palfride,  
Crede quod habes, et habes."

Which have been thus freely translated:—

"Remember you told me  
Believe and you'll see,  
Believe it a body and a body 'twill be;  
So should you tire walking  
This hot summer-tide,  
Believe your staff's Dobbin  
And straightway you'll ride."

Not only does the imagination play us strange tricks, but our affections and passions are liable to become inordinate and abnormal, and they lead to many bodily disorders. Not only may this be said of fear, anger, revenge, grief &c., but also of love, hope, joy, friendship &c.; so that even our enjoyments and duties as well as our vices may become "scorpions to whip and sting us." The poets have not overlooked these facts, as in the following examples:

"She never told her love,  
But let concealment, like a worm I' th' bud,  
Feed upon her damask cheek: she pined in thought,  
And, with a green and yellow melancholy,  
She sat, like Patience on a monument  
Smiling at grief."—*Shakespeare*.

"Dum spectant oculi lesos lædantur,  
Multique corporibus transiitio nocent."

Or thus in English :

"Viewing sore eyes, eyes to be sore are brought,  
And many ills are by transition caught."

"For deadly fear can Time outgo,  
And blanch at once the hair."

"O how fear did make her colour rise!  
First red as roses that on lawn we lay,  
Then white as lawn the roses took away."

I hold the views of Mr. Herbert Spencer, who believes in "the constant coöperation of all the leading nervous centres in every thought and emotion," and therefore, in my judgment, our division of the mind into various faculties or powers is merely to facilitate our conception and study of mental acts—or, more strictly speaking, is an attempt to analyse the thing which is an entirety, and to divide that which is indivisible. According to this view an act of the intellect or an act, say, of volition is in either case an act of the whole mind, and we love or fear &c. with the whole mind, not with a single part or parts of it; and in this sense in what follows I shall endeavour to consider the mind's action on the body in the production and in the removal of diseases. There are very many instances of the hair turning grey or white in a few hours, through sudden fright or grief, but on these I shall not dwell, since I am not aware that we possess any mental influence that can undo this misfortune; for we know of no other power whatever that can make "one hair white or black."

Sir Thomas Watson says that diabetes may be caused by distress or anxiety, and Dr. Copland states that mental exertion and the depressing passions may give rise to the disease. It has also been observed that in families where the disease is hereditary, if one member of the family should suffer from it fear will hasten its onset in other members. The following statements concerning the influence of anxiety and disappointment on the inhabitants of France during the Franco-Prussian war are on record. "A young lady was standing with her father at the window when the Prussian soldiers came down the *tranchée* and she was seized with shivering; her father, who could feel her trembling, said—'You need not be frightened; they will not hurt you.' But she had received a shock from which she became quite blanched and lost her sleep and flesh, and she has never been able to keep her feet warm from that day, now two years since." In a letter to THE LANCET, dated June 21st, 1871, the writer states: "The true hope of the Parisians, which they fondly cherished, and which in a great measure kept them alive during the siege, was most cruelly blighted—and you may imagine their disappointment when the capitulation of the city was announced; the mental shock to some was such that they almost lost their reason. But the most remarkable effect of the siege was the aged appearance of some of the inhabitants. Men and women alike seemed to have passed over at least ten years of their existence in half as many months." There are many well-authenticated instances of hydrophobia being produced by fear: for example, "A boy was bitten by another boy in anger. There was no evidence of rabies in the biter, but the boy died. He was seized with hydrophobia forty-eight days after the bite and died in twenty-four hours."<sup>1</sup> It is recorded by Gaubius that "a soldier quarrelled with a woman, who thereupon bit his hand. He was seized with rigor and died." An enraged Italian youth, unable to revenge himself, bit his own hand and was seized with a deadly fear of water, as if bitten by a rabid dog. Malpighi asserts that his own mother died of hydrophobia a few days after being bitten by an angry epileptic. To Carlyle is attributed the saying, "Conscience is very much a matter of the condition of the liver," and at all events one may safely say that bile and bad tempers, or even melancholy, go together. Anxiety and grief, fear and anger will all produce jaundice. So it would seem that mental states are produced by disorders of the liver and disorders of the liver by mental states—they mutually react on each other. Dr. Carpenter remarks that "it is perhaps not an ill-founded opinion that melancholy and jealousy have a tendency to increase the quantity and to vitiate the quality of the biliary fluid;" and that "it is certain the indulgence of those feelings produces a decidedly morbid effect by disordering the digestive processes, and thus reacts upon the nervous system by impairing its healthy nutrition." The influence of sudden fright in checking the secretion of bile and so occasioning jaundice is adduced by Bichat as a striking proof of the connexion of mental states and the secreting organs; and so Juvenal writes, "Quid referam quantû succum

jecur aident via." Dr. Murchison observes that "there is good evidence that nervous influences may not only cause functional derangement but cure structural disease of the liver." Diseases of the spleen are also said to have been caused by certain states of the mind, as "thought, anger, care, sorrow, fear, or grief," or worry about many matters. The ancients believed that anger and desire resided in the gall, fear in the heart, and joy in the spleen, so the poet—

Cor ardet, pulmo loquitur, fel commovet iras  
Splen ridens facit, cogit amore jecur.

Excessive joy as well as excessive grief may even cause death. Wives on receiving their husbands back safe and sound, who had been reported as certainly lost, mothers on embracing their sons who were thought to be dead, poets on coming to sudden honour and fame, and prisoners on being pardoned or suddenly released, have died from the shock of sudden joy. Rheumatism has been produced by fright, and this oftentimes seems to be the only exciting cause; and gout is proverbially dependent on mental influences; fretting, worry, domestic vexation, joy, anger, terror and excessive mental strain are all exciting causes of this disease.

Sydenham observes that "melancholy is pre-eminently the inseparable companion of gout. Hence, those who are liable to it are so wont to tire and overwhelm the animal spirits by long and deep thought, that excessive exertion of this sort, even without the artificial aid of reading, makes the proper preservation of the economy of the body an impossibility, for which reason (as it seems to me) gout rarely attacks fools. Those who choose may except the present writer." Joy, grief, or disappointment will, according to many writers, occasion fever. The following instances may be named. Dr. Rush observes that "the attendants upon the sick in bilious yellow fever in Philadelphia in 1798 were materially influenced by the prospect of the patient's recovery; so long as there was hope they often escaped, but when hope was extinguished they were frequently attacked by the disease." Dr. Jackson states that "the garrisons of Savannah and York Town remained healthy so long as these towns were besieged, while Savannah became affected with fever when the French and American armies retreated from it, and York Town when it capitulated. In both instances the mental tone of the inhabitants ceased to be wholesomely maintained; joy in the former did not prevent the deleterious influence of their action; and grief and disappointment in the latter produced their natural fruits."

Sir Samuel Baker, in his "Albert Nyanza," after describing the symptoms of the fever which prevailed and proved frequently fatal in Africa, and was of an intermittent type, observes that "any severe passion of the mind, such as grief or anger is almost certain to be succeeded by fever in this country, just as full occupation of the mind was found to act as a prophylactic against it." Several examples of the power of the will over the bodily functions are recorded—e.g., of a man named by Dr. Darwin who could stop the motion of his heart when he pleased and of another who could by voluntary effort cause the action of the bowels at any time in half an hour.<sup>2</sup> Colonel Townsend's case, so often quoted, is doubtless very remarkable. It is said of him that he possessed the remarkable facility or power of throwing himself into a trance at pleasure. "The heart apparently ceased to throb at his bidding, respiration seemed to be at an end, his whole frame assumed the icy chill and rigidity of death..... his mind during the trance was as utterly devoid of consciousness as his body of animation. In this state he would remain for hours, when these singular phenomena wore away, and he returned to his usual condition." The celebrated John Hunter had great will power. Speaking of animal magnetism, to which his attention had been drawn, he observes: "If any person is affected by it, it must be by the imagination being worked up by the attention to the part expected to be affected." In this belief he went to be magnetised and observes, "When the magnetiser began his operations and informed me that I should feel it at first at the root of the nails of that hand nearest the apparatus I fixed my attention on my great toe, where I was wishing to have an attack (fit of the gout). Whenever I found myself attending to his tricks I fell to work with my great toe—working it about &c.,—by which means I prevented it having any effect upon me." During an alarming attack of spasm, attended by unusual depression of

<sup>1</sup> THE LANCET, July 14th, 1890

<sup>2</sup> Philosophical Transactions, p. 39.

the heart's action, Hunter is said to have been able to keep up the respiration, as he thought, by a voluntary effort; but I am disposed to think that, whatever may have been the state of the heart at the time the respiratory centres were unaffected, and therefore he breathed naturally, and not by any voluntary action he himself put forth. The case of Colonel Townsend is singular in many respects, and among others that he is said to have discovered by accident the power he had to suspend the action of the heart; it is probable, therefore, that the cardiac suspension he could produce voluntarily was the result of some peculiarly nervous state, which by repetition had previously become automatic; and this same feeling or sensation rendered it possible for him at times to precipitate the act. Colonel Townsend's cases teach us nothing—merely exciting our wonder; but Hunter's power of attention, as described in his mode of dealing with the magnetised, really contains, as has been said, "the gist of all that has been written since on the influence of expectant attention on the imagination." Shakespeare has two lines in "King John" of gravest import:—

"How oft the sight of means to do ill deeds  
Makes deeds ill done."

And on the ludicrous side of the thought we have the following experience of John Hunter. "I went," he says, "to see Mrs. Siddons' acting. I had full conviction that I should be very much affected, but unfortunately I had not put my handkerchief in my pocket, and the distress I was in for want of that requisite when one is crying, and a kind of fear I should cry, stopped up every tear, and I was even ashamed I did not, or could not, cry."

Next notice certain cases of disease which go under general and arbitrary names. Hysteria, which doubtless often proceeds from some anomalous action of the mind and feelings, but which likewise is often mere perverseness and little understood; disappointed love, or ambition, or social hopes and expectations, or inordinate passions or desires in any direction, and an inordinate craving for sympathy or undue attention; and, in some instances, disinclination for any kind of employment or even amusement, are among the most prominent exciting causes of hysteria. In other instances in connexion with it, and as a part of this disease, we meet with deception and cunning without apparent purpose or end; but, I conceive, for the most part to arouse sympathy or to avoid work or exertion. A case came under my notice some years ago where a young woman lay in bed two days apparently in a state of deep insensibility, inasmuch that the medical man in attendance thought she had serious brain disease; but on being freely doused with cold water over the head and face she speedily came to her senses and called out, "I'll tell my father!" In another case, that of a lady's maid seen by a medical friend of mine, to whom he was called at midnight, the free use of cold water brought her out of a severe fit in which she was violently struggling, and jumping up she cried out in a rage, addressing the medical attendant, "You're a devil!" In another case the patient was a half-drunken woman who had fallen down in a fit opposite my house, and by her struggles was exciting much sympathy, but on my pouring over her face a can of cold water she leaped up and said, "You're Dr. —; give us a drink." Other cases yet more strange would seem to be produced for some purpose or from some morbid feeling by imitation. Thus the hip, the knee, the ankle, the shoulder, the elbows, the wrist or the fingers may become immovable and highly painful, as if from severe disease of the joints; yet, as the subsequent history has shown, they have become instantly well again under some emotional or impulsive effort of the patient, and that to the general surprise of experienced medical attendants. "Expectation of the action of a remedy causes us to experience its action beforehand."—Umzer. "I am confident that I can fix my attention on any part until I have a sensation in that part."—John Hunter.

In the preceding remarks I have given numerous instances in proof of the influence of the mind in producing various diseases of the body; and I have now to show its power, and the limits of that power, as a psycho-therapeutic agent. I shall exclude from consideration mesmerism, or animal magnetism, as it is designated, and also Braidism, another form of animal magnetism, as they were employed by Dr. Elliotson and Mr. Braid as agents in the treatment of disease; for their effects even in the hands of these and other able observers were for the most part uncertain, often illusory, and always more or less mysterious. I shall also pass over the wonderful stories which are told concerning "tractors" (pieces of wood or metal &c.) which, after having

been employed by certain enthusiasts in hospital practice, have long been laid aside in England as, if not useless, at least as quite undeserving the praise once bestowed upon them. I shall deal in the same manner with the administration of "bread pills" and other inert substances, whilst assuring the patient that they are new and most powerful remedies, inasmuch as, requiring to be used both on the part of the patient and the physician with much mystery, untruth and quackery, the whole procedure is repugnant to every right and honest feeling.<sup>3</sup> These things being excluded from consideration, either as unworthy or uncertain methods of treatment in disease, we find that the influence of the mind in curing bodily ailments is extremely limited. I shall now proceed to illustrate this influence by examples, seek to define its limits and inquire to what extent it may be legitimately employed.

"A young lady, in other respects healthy, had gastric nerves so wayward that they would permit only a small amount of food to remain on the stomach. This condition produced great debility and inconvenience. Her physician told her that she might by a strong mental effort free herself from the ailment. She tried her best, but failed. It became apparent that she did not possess sufficient will power for the task. The physician, therefore, decided to assist the will by inducing strong emotion with respect to the ailment, and this he effected in the following manner. Going to the future husband of the lady he urged him to inform her that their union could not take place until she was cured. The time fixed for the marriage was close at hand, and the shock of such news had an immediately beneficial effect. Her gastric nerves began to resume their normal functions from the moment of that interview." "The wife of a scientific man was seized with what is called hysterical paralysis of the lower limbs. She was informed that her inability to walk was not the result of any organic change, but merely of nervous debility, and she received the usual routine advice—that she must fight against her feelings, and make constant efforts to overcome the paralysis by force of will." She followed this advice for a long time, but getting gradually worse she gave up all attempts at walking and resigned herself to the ignominy of a Bath chair. One summer's day she was left on the seashore by her husband, who went a short distance for a newspaper. During his absence a half-intoxicated Highlander approached the lady and threatened to kiss her. In terror she jumped from the Bath chair and made off in search of her husband. From the date of that incident she gradually recovered the power of locomotion."<sup>4</sup> "A patient suffering from hypochondriasis, who thought he was dying from liver disease, upon receiving information of the death of his brother, who actually died of a scirrhous liver, immediately staggered and fell down, crying out that he was dead. Dr. Crawford of Baltimore being sent for, he immediately attended, and on being informed of the notion which had seized the hypochondriac exclaimed: 'Oh, yes, the gentleman is certainly dead and it is more than probable his liver was the death of him. However, to ascertain the fact, I will hasten to cut him open before putrefaction takes place.' He called for a carving knife, and, whetting it as a butcher would when he proceeds to open a dead calf, he stepped up to him and began to open his waistcoat. The hypochondriac became so terribly frightened that he leaped up with the agility of a rabbit, and, crying out, 'Murder! murder! murder!' ran off with a speed that would have defied a score of doctors to catch him. After running a considerable distance, until he was almost exhausted, he halted, and not finding the doctor at his heels soon became composed. From that period this gentleman was never known to complain of his liver, nor had he for more than twenty years afterwards any symptoms of this disease."

Hydrophobia, it is thought, may be prevented or cured by a firm determination to resist it. A Mr. C— was severely bitten by a cat which died the same day hydrophobic. He appears to have thought little of the circumstance, and was certainly not nervous or imaginative in regard to it. Three months, however, after he had received the wound he felt one morning great pain in the arm accompanied by extreme thirst. He called for a glass of water. The sequel will be best told in his own words: "At the instant that I was about to raise the tumbler to my lips a strong spasm shot across my throat. Immediately the terrible conviction came to my mind that I was about to fall a victim to hydrophobia—

<sup>3</sup> Another "ism"—hypnotism—is on its trial, but I fear nothing will be gained in medicine by its employment.

<sup>4</sup> The Nineteenth Century, November, 1887.

the consequence of the bite that I had received from the cat. The agony of mind I endured for one hour is indescribable; the contemplation of such a horrible death as that from hydrophobia was almost insupportable; the torments of hell could not have surpassed what I suffered. The pain, which had first commenced in the hand, passed up to the elbow, and thence to the shoulder, threatening to extend. I felt all human aid was useless, and I believed that I must die. At length I began to reflect on my condition. I said to myself either I shall die or I shall not; if I do it will only be a similar fate which many have suffered and many more must suffer, and I must bear it like a man; if, on the other hand, there is any hope of my life, my only chance is in summoning my utmost resolution, defying the attack and exerting every effort of my mind. Accordingly, feeling that physical as well as mental exertion was necessary, I took my gun, shouldered it, and went out for the purpose of shooting, my arm-aching the while intolerably. I met with no sport; but I walked the whole afternoon, exerting at every step I went a strong mental effort against the disease. When I returned to the house I was decidedly better; I was able to eat some dinner, and drank water as usual. The next morning the aching pain had gone down to my elbow; the following day it went down to my wrist, and the third day it left me altogether. I mentioned the circumstance to Dr. Kinglake, and he said he certainly considered that I had had an attack of hydrophobia, which would possibly have proved fatal had I not struggled against it by a strong effort of mind." If it be true that hydrophobia, or symptoms closely resembling it, may be produced by fear and excitement after being bitten by an animal, rabid or otherwise, and that by a strong mental effort these symptoms may be subdued, as in the case which has just been referred to, it is most important that the fact should be generally known. There is good evidence to show that this is by no means an isolated case, and the physician should be careful at least not to encourage the idea of hydrophobia in a patient who has been bitten by a suspected animal; but indeed it would be well for him rather to scout the notion so that the fears of his patient may be as far as possible allayed. One case is recorded in which a man, who had been bitten by a dog, through fear remained in bed for several days, believing he was the victim of hydrophobia, but he became speedily well on being told by his physician that hydrophobia caused death much within the time he had already remained in his bed. "If it were understood," says Dr. Spitzka, "that fear and expectant attention may not only develop serious nervous symptoms, but actually cause death, many who are threatened with hydrophobia would cultivate healthful self-control. .... A number of cases are on record in which patients suffering from the most agonising symptoms of rabies recovered on hearing that the dog which bit them was alive and well."

Hysteria is evidently a disease over which the mind has much power; hence in many phases of this malady it has been thought a sufficient explanation of the symptoms to say "she won't will." The following example is recorded by Mr. Skey, late surgeon to St. Bartholomew's Hospital: "A young lady of sixteen, who for many months had been suffering from an inversion of the left foot, which was twisted at right angles with the other, was treated by orthopædic surgeons with an elaborate apparatus of splints. Neither they nor Mr. Skey (though he recognised the nature of the affection) succeeded in curing it. Psychological agents, however, effected a cure in a few minutes. She willed to use her foot like other people, and she did. She accompanied her family to a ball, her foot as she entered the ball-room being not yet restored to its normal position. She was invited to dance, and under this novel excitement she stood up; and to the astonishment of her family she danced the whole evening, having almost suddenly recovered the healthy muscular action of the limb. She came to see me," adds Mr. Skey, "two days afterwards. She walked perfectly well into my room, and paced the room backwards and forwards with great delight. The actions of the limb were thoroughly restored, and all trace of the previous malady had disappeared." The good effects of a resolute bearing on the part of the physician and the free use of cold water in hysterical fits have already been mentioned. Another case comes vividly before me, that of a young woman who, as I entered the house, having been hastily summoned, was said to be dying from some imaginary swelling of the throat. In this case also a firm demeanour and a plentiful dousing with cold water quickly effected a cure, though the doctor was said to be cruel and unfeeling.

Faith and hope are doubtless valuable adjuncts in the treatment of disease. Hence besides the many well-authenticated cures effected by visiting religious houses, the shrines of saints, strong faith in the prayers of holy men and women, relics, holy water, charms &c., there is every reason to believe that the physician who by his personal bearing and firmness gains the entire confidence of the patient has an infinitely better chance in the treatment of disease than one whose demeanour and character fail to impress him favourably. The above instances must suffice to illustrate the subject of psycho-therapeutics. Many more might be given, but they would be similar in character. On considering the whole subject I think it must be admitted that while the influence of the mind in the causation of diseases is very great, its influence in curing diseases, or the use the physician can make of it for this purpose, is very small and limited. Fear, like mesmerism or tractorism, can very rarely be resorted to, for it has been well observed, "Who can calculate the effects of fear; and, consequently, who would dare to make use of it as a curative agent?" For example, it is possible that a rough intoxicated Highlander may cure a lady of hysterical paralysis; the shock of a railway accident stave off an attack of rheumatic fever, as it is said to have done in one instance, or the threat to dissect a hypochondriac perform a cure. But what practical use can be made of such knowledge? It appears to me, then, that the sum total of what can be done by psycho-therapeutics must be effected by a firm self-reliant bearing on the part of the physician in dealing with cases of hysteria and nervous diseases generally. I have shown already that many hysterical disorders, and even hydrophobia itself, may be cured by encouraging the patient to exert a strong determination (volition) to conquer his disease. Faith and hope too may be stimulated in the sick; this the physician can do, not by inducing them to visit the shrine of a saint or exciting superstitious feelings within them, but by his mode of addressing his patients in the hope and confidence which he endeavours to inspire and in the removal of everything calculated to depress them. One of our noblest poets has said,

"Mirth, music, friendship, love's propitious smile  
Chase every care."

And to whatever extent one may be disposed to discount the saying of the poet I think that the influence of music has not been utilised in the treatment of disease as it might have been. Whoever has visited the theatre or the opera must be familiar with the soothing and generally pleasant influence that music possesses, and all the more so if some contrivance has been made so as to have the musicians out of sight and that the music may sound as if at a distance; the distant sound of bells, of a waterfall or of singing is alike pleasant and soothing, and all the more so if it be heard at night or in quiet places which invite to meditation. An ancient writer says of music: "It makes a child quiet; the nurse's song, and many times the sound of a trumpet on a sudden, bells ringing, a carman's whistle, or a boy singing some ballad tune early in the street, alters, revives, recreates a restless patient that cannot sleep in the night."<sup>5</sup>

I am persuaded that in some form and in suitable cases, of which the physician would be the best judge, music might be made more serviceable in treatment, provided it were judiciously employed and kept from assuming the garb of quackery or mystery, and in this manner becoming ridiculous. Music was employed, as we know, so far back as the days of the first Israelitish king, for the Scriptures state: "When the evil spirit from God was upon Saul, David took an harp and played with his hand; so Saul was refreshed and was well, and the evil spirit departed from him." It is strange, therefore, that in this day it has been so greatly neglected. There is an article in a periodical of the day on "Rest of Nerves," and among other means the writer advises men who are harassed with many business or other cares in this busy worrying age to rest in bed, at least one day in the week, that the overworked, jaded nervous system may be refreshed and recuperated—and the advice is sound and judicious, although it may perhaps seem absurd and a mere jest to the healthy and vigorous. This plan, however, is only suggested by the writer as a preventive against the evil effects of the worry and cares of business or the bustle of life in these days; but the mind has many other things to bear besides these, which, I fear, neither one day's rest in the week in bed, or even two, will

<sup>5</sup> The influence of "sweet sounds," or, in other words, of music, is now being tried for certain diseases in some of our large hospitals.

help us to sustain with fortitude and calmness. In that very learned and witty book, "The Anatomy of Melancholy," the writer, quoting from Roger Bacon on the way to prevent the ill effects of mental troubles on the body, observes: "If it be any disgrace, abuse, temporal loss, calamity, death of friends, imprisonment, banishment, be not troubled with it, do not fear, be not angry, grieve not at it, but with all courage sustain it. If it be sickness, ill success, or any adversary that hath caused it, oppose an invincible courage, fortify thyself by God's word, or otherwise, set prosperity against adversity (as we refresh our eyes by seeing some pleasant meadow, fountain, picture, or the like), recreate thy mind by some contrary object, with some more pleasing meditation divert thy thoughts. A philosopher was bitten by a mad dog, and as the nature of that disease is to abhor all water and liquid things and to call up the picture of a dog before those affected by it, he went for all this reluctantly to the bath, and seeing there (as he thought) in the water the picture of a dog with reason overcame the conceit—*quid cani cum balneo*. What should a dog do in a bath? A mere conceit." It appears then finally that Faith and Hope are the two great principles which the physician must encourage or seek to evoke in his patient. The diseases to which man is liable may be looked upon as so many enemies which lay siege to the citadel of his life, and often he is so fiercely assailed by them that he finds no help or defence in himself; and it is then that the physician, coming to his rescue with the powerful allies, Faith and Hope, may perchance create within him a courage which will enable him to make, at least, a brave stand against his foes; and he who expects more than this from the influence of the mind in the removal of bodily diseases will, I think, be disappointed.

Bishop's Telfington.

## GUNSHOT INJURIES TO THE EYE: THE POSSIBILITY OF THEIR MORE CONSERVATIVE TREATMENT.

By GEORGE FERDINANDS, M.D., C.M. ABERD.

THE shooting season invariably confronts us with the *pros* and *cons* of enucleation by its presentation of cases where doubt is entertained whether a foreign body exists in the eye or whether the injury sustained by that organ is sufficient to demand its removal. Professor Theodor Leber, in his recent address before the Ophthalmological Society, very lucidly demonstrated how different chemical substances seem to possess different pus-producing qualities depending upon the amount of irritability each was capable of producing. We are told that "purulent inflammation set up by the action of chemical substances has not the same power of extension as that due to the action of microbes." This is an important statement, and its importance is enhanced, since clinical observation strongly supports Professor Leber in his further remark that "the inflammation caused by chemical agents remains more or less limited to the affected area." These facts, viewed in conjunction with the theory of germ transmission along the lymph channels of the optic nerves, undoubtedly demand a reconsideration of the bases generally accepted as justifying enucleation. Especially is this so in those cases where only an aseptic inflammation may with reasonable grounds be anticipated. Such reconsideration may lead to modified measures in a large proportion of gunshot injuries to the eye. A shot is a comparatively aseptic body, and usually produces little disturbance when lodged in the eyeball.<sup>1</sup> In these cases the period of observation might with safety be prolonged. In fact, the hasty removal of eyes thus injured is to be deprecated. An attempt should be first made to extract the foreign body from the exudation around, from which, as suggested by Professor Leber, cultivations may be made, to discover the septic or aseptic nature of the injury. Another advantage from delay may be gained in cases where doubt exists as to the presence of a shot in the eye. The following instances which have come under my own observation may exemplify this.

CASE 1.—R. B.—, in August last, had his left eye struck

<sup>1</sup> Unfortunately Professor Leber makes no mention of lead.

by a spent shot. The case was seen by me a week after the accident. The upper eyelid was slightly swollen and ecchymosed, and right in the centre, nearer the nasal end of the lid, was a well-marked wound, almost healed. It was difficult to judge whether the wound had extended to the whole depth of the lid. Beyond these, there were no perceptible signs of external injury. V. = barely  $\frac{1}{8}$ ; and on examination the fundus showed a large subretinal hæmorrhagic patch below the macula lutea—i.e., just on a line with the wound on the eyelid. The appearance the hæmorrhage presented was certainly suspicious, for it consisted of a dark central spot, slightly elevated, and surrounded by an irregular zone of a lighter shade. The vitreous near the hæmorrhage was slightly hazy. No other evidence of internal injury could be noticed in spite of careful examination, especially of that part of the fundus lying adjacent to the injured eyelid. The hæmorrhage retained its character and size for over three weeks, and then suddenly became absorbed in a few days, leaving only pigmentary traces, and when the case was last seen V. =  $\frac{1}{8}$ .

CASE 2.—A. M.— was also accidentally shot just below the left eye, one centimetre from the lower lid, where there was a well-marked punctured wound, almost hidden by the swelling externally; the appearance round the eye was that of a typical "black eye." On careful palpation, rendered difficult by the swelling, no foreign body could be felt beneath the skin. The eyelids were with difficulty separated, and the external examination of the eyeball revealed only slight subconjunctival hæmorrhage towards the outer side. The examination of the fundus proved difficult, especially as the pupil was small; but a distinct subretinal hæmorrhage could be made out a little way below the disc. Ice and atropine were ordered. After three days the swelling subsided considerably, and a thorough examination of the fundus revealed only the single hæmorrhage seen before; it presented, however, the same peculiar appearance of a dark, jagged central spot and a lighter zone around it. On palpation over the wound a week after the accident the presence of a pellet embedded deep beneath the skin in the subcutaneous tissue could with a little trouble be felt. This discovery removed all doubt as to there being any foreign body in the eye itself. The hæmorrhage rapidly diminished in size and density, and a fortnight after the accident vision had improved from the perception of only fingers at 6 ft. to  $\frac{6}{6}$ .

CASE 3.—I am unfortunately unable to give precise notes of this case. A few years ago I was asked to assist at an enucleation. As far as I can remember, the history of the case was as follows. About a month before the date of operation the patient, while out shooting, was accidentally shot in the face. He distinctly felt something strike the eye. On examination there was either no apparent wound of the eyeball or only a slight abrasion. However, a well-marked hæmorrhage near the disc was easily recognised, looking very much as if a foreign body was lodged in its centre. The case was carefully examined from time to time by two medical men, but the persistence of the hæmorrhage without any apparent diminution of its size or density only served to confirm the suspicions entertained that the foreign body was present; and as the patient and his relatives were anxious about the matter it was decided to remove the eye. This was done, and on examining the eyeball no foreign body was found, neither was there much evidence of any hæmorrhage left.

The first two cases were evidently instances of mere concussion of the eyeball, the hæmorrhage being caused by *contrecoup*. In fact, injury to the fundus by this peculiar phenomenon is by no means uncommon, and is especially noticeable in blows or injuries received over the eyeball. The third case must have been identical with the two former. It may have been a case in which the shot had traversed the eyeball and entered the orbit, but there seems not to have been sufficient evidence to suggest this. The case serves to show how necessary it is that a final examination of the eye should be made immediately before it is excised. Had too precipitous measures been adopted in the first two cases useful eyes would have been unnecessarily sacrificed.

The whole subject is replete with difficulties. Each case has to be treated on its own merits, and consequently depends on the judgment of the surgeon who has had drilled into him all the dangers of sympathetic ophthalmitis, and who naturally resorts as early as possible to extreme radical treatment. It is well, therefore, to remind him that there are

certain cases which do not require these radical measures, and that they can only be recognised by an extension of the period of observation usually considered necessary in such cases.  
Aberdeen.

## NOTE ON DIASTASIS THROUGH NECK OF FEMUR.

BY DAVID WALLACE, F.R.C.S. EDIN.

DIASTASIS through the neck of the femur is described as a rare injury in our text-books, and Dr. Hamilton refers to only three problematical examples.<sup>1</sup> In the "Archives of Surgery"<sup>2</sup> the author refers to the detachment of the upper epiphysis of the femur, and specially directs attention to its absence from museum collections, no specimen being extant, and he also refers to the rarity of any clinical descriptions of the injury. Mr. Hutchinson, however, states that he is "confident that it is an accident which is not infrequent." In the first week of April of this year, a few days before I saw Mr. Hutchinson's account of this injury, one of my students asked me to see a case of supposed old-standing dislocation of the hip. On examination of the patient I concluded that it was probably a diastasis through the neck of the femur, not a dislocation at the hip-joint. The history and condition were as follows:—

M. B—, aged eleven years, a girl of good build, tall and strong for her age, was said by her mother to have been a well-nourished child, who walked before she was nine months old. When nine months of age she fell out of her cot, and the mother believes that when falling the right foot caught between the bars, so that the leg was severely twisted. The child cried, and refused to stand up or allow the leg to be moved. There were pain and swelling in the neighbourhood of the hip. Hot fomentations were applied during the first few days, but in the course of two or three weeks (?) a doctor was called in, who said the hip-joint was dislocated, and attempted to reduce it, but failed to do so. Two or three years later the child walked with a distinct halt, and the hip was prominent. At this time the mother showed the girl to a "bonesetter," who tried "to put the bone in," but also failed. The swelling and lameness have persisted until now, but the girl walks, runs, and jumps without any pain as a general rule, although after much romping she now and then complains of pain at the hip. No other injury has been sustained, and there is no history of joint or chest disease in the patient or in other members of the family.

*Present state.*—The patient complains of no pain or discomfort, but says she is lame and that the "leg comes out at the haunch." She walks with a distinct limp, and when she stands the right foot is observed to be a little more everted than the left, while there are marked drooping and rotation forwards of the right anterior superior iliac spine. The right limb is evidently shorter than the left.

*Measurements.*—1. From anterior superior iliac spine to internal malleolus: right, 27 in.; left 29½ in. 2. From anterior superior iliac spine to tip of patella: right, 14 in.; left, 16 in. 3. From tip of trochanter major to external condyle: right, 13½ in.; left, 14½ in. Nélaton's line on the right side passes 1½ in. below the tip of the trochanter; on the left side it is normal.

*Movements.*—The right thigh can be flexed on the abdomen, but not quite so fully as the left. Rotation of the right is greater than the left. Abduction is equal on the two sides. When the right leg is flexed on the thigh and the thigh on the abdomen the trochanter major is felt as a distinct prominence midway between the anterior superior spine of the ilium and the ischial tuberosity, and moves through a much wider radius than the left. No rounded prominence corresponding to the head of the femur can be felt, but there is a distinct mass of bone projecting internally to the trochanter, which moves with the trochanter. (Is it the atrophied head of the femur in an old-standing dislocation, or a short process representing the neck thickened by osteophytes?) When rotary movements are carried out a rough grating is felt deeply seated. The right leg is thinner than the left, but is muscular and shows no sign of malnutrition.

From a consideration of the above points in this case I

conclude that it is a diastasis of the neck of the femur, chiefly because of—(1) a history of injury at an early age, but subsequently to the child walking; (2) no history or appearance of tuberculous disease; (3) marked displacement of the trochanter major upwards, associated with very free movement and eversion of the foot; and (4) a slight degree of shortening of the femur.

Edinburgh.

OF

## HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

### MIDDLESEX HOSPITAL.

A CASE OF SUICIDAL WOUND OF THE THROAT COMPLETELY SEVERING THE LARYNX AND OPENING THE GULLET; SUTURING OF EACH; SURVIVAL DURING SEVERAL HOURS.

(Under the care of Mr. HULKE.)

A POINT of forensic and physiological interest in this remarkable case is the allegation that the patient was able to speak in a whisper so as to be understood by the constable called to him soon after the infliction of the wound, although the upper portion was separated by an interval of several centimetres from the lower part of the larynx and one vocal cord was damaged. Closely questioned on this point, the constable's testimony remained unshaken. The absence of respiratory embarrassment in the presence of the deep retraction of the lower part of the larynx is another notable circumstance. Its probable explanation lies in the free access of air through the widely gaping external wound, the rigidly patent lumen of the severed cricoid cartilage and the diminished call on the lungs in presence of the very great loss of blood, and the deep shock. The insensibility to pain shown by the patient during the examination of his wound and the suturing of the gullet and larynx merits a passing notice; it is a not uncommon circumstance in shock from injuries, and as a matter of common experience it seems to be more pronounced in instances of self-inflicted wounds, where it appears to be largely dependent on the mental condition attending these injuries. That this patient was not suffocated by the copious entrance of blood into the trachea may have been due to the widely gaping external wound affording free outlet for the flowing blood, the external escape of which might have been favoured by his lying on his side. It was remarkable that the great cervical bloodvessels escaped injury, as did also the thyroid gland. The retraction of the trachea towards the chest gives some measure of the longitudinal elastic tension of this tube under normal conditions. Owing to the jagged irregular manner of severance of the larynx and the detachment of small pieces the upper and lower parts could not be everywhere adjusted with perfect accuracy. Stout silk sutures were used for sewing the larynx together, being better able to withstand the great downward pull of the trachea and becoming more slowly disintegrated than catgut, and therefore holding longer.

A. C—, aged twenty-three, was received into Founder ward in the early morning of April 15th, 1891. He had very shortly before been found on the floor of a room with his throat cut. His clothes were soaked with blood, which in small quantity was still trickling from a gash in the front of his throat at the level of the cricoid cartilage. The surface of his body was cold, and had the colour and translucency of white wax. His pulse was scarcely perceptible (it was so small and weak); its beats were 60 per minute; respiration 16 (shallow and noiseless). His face had an anxious expression. He was perfectly conscious. When spoken to he tried to answer; his lips moved, but he was voiceless and no sound was emitted. He had swallowed, we were told, a little brandy-and-water, but most of this had run out through the wound. In the casualty receiving-room a hypodermic injection of ether had been given him before it was deemed prudent to move him to the ward. The police

<sup>1</sup> Hamilton: *Fractures and Dislocations.*

<sup>2</sup> Vol. III., No. 12, April, 1892.

constable who brought the patient to the hospital said that he found him lying in a pool of blood on the floor of a room in a house in a neighbouring street. A razor lay on the floor about a yard distant from him. He was conscious and breathing quietly. He asked "Where am I?" To the question "Who did it?" he answered in a loud whisper "Me." On the table in the room was a note in his handwriting leaving his body to the hospital, "as it is not worth burial." The gash was not quite central, but it reached rather more to the left than to the right side of the neck. Its length was about five centimetres and it gaped about two centimetres at its middle. Its edges were ragged, and when drawn apart a deep irregular hollow was apparent, the back of which was formed by the prevertebral muscles and vertebral column, on which were seen the lowest part of the pharynx and the œsophagus. The former of these, near its junction with the latter, had in it a wound two centimetres long, opening its lumen. When the upper tegumental margin of the deep gash was raised the upper part of the severed cricoid cartilage came into view; it, with the higher laryngeal structures, had been drawn up within the mandibular arch. The division of the cricoid cartilage had been effected by a succession of sawing cuts, which had also detached completely several small pieces of it which were lying loose in the wound. The lower part of the cricoid cartilage in connexion with the trachea had retracted so much towards the root of the neck that it could not immediately be seen, but with a laryngeal mirror it was recognised at the level of the upper opening of the thorax. First, bleeding having been completely arrested, the cut in the gullet was closed with three sutures. Next, the lower part of the cricoid cartilage was seized with a vulsellum forceps, pulled up and drawn forwards to the level of the margins of the tegumental wound, which made it possible without risk of suffocation to flush out the deeper recesses of the wound with mercuric perchloride solution. This done the upper and lower parts of the larynx were united with two stout silk sutures on each side passed through the cartilages. These held the parts of the larynx firmly together. A large Trousseau's tube was previously inserted in the trachea. A little iodoform was dusted upon the cut surfaces of the wound and this was protected from direct exposure to ward atmosphere by a couple of layers of carbolised gauze strained over an improvised wire cradle serving as a respirator. Little pieces of ice from time to time placed in his mouth seemed to assuage thirst, which by signs he indicated to be very great, nutrient suppositories and enemata were ordered. Throughout the day he was quiet, but at 11.30 p.m. he grew restless, and he tried to leave his bed. For this one-third of a grain of acetate of morphia was hypodermically injected. After this he was again quiet. At 2.30 a.m. on the 16th (next day) death occurred.

At the necropsy, in addition to the laryngeal injuries mentioned, several cuts were found in the thyroid cartilage, especially on the right side, passing completely through it; the arytenoid cartilages had been severed from the cricoid and the right true vocal cord was divided. The bronchi and lungs were found congested, the right lung deeply so, and the left lung emphysematous. In the anterior mediastinum were calcified remains of a caseated lymph gland. The aorta was slightly atheromatous. The left testis had not descended; it was atrophied.

### MORPETH DISPENSARY.

#### CASE OF ACUTE YELLOW ATROPHY OF THE LIVER; NECROPSY.

(Under the care of Mr. STANLEY YEOMAN.)

ON account of the extreme rarity of the above disease and the unprecedented age at which it occurred, a record of the case will prove of value. Bristowe writes: "Cases of malignant jaundice have been observed chiefly in adults and in women more frequently than in men. But children are now and then attacked with it, and we have recently seen a typical case in a child two and a half years old." Groves described a case in a child aged twenty months. The characteristic symptoms of the disease in Mr. Yeoman's patient were well-marked absence of febrile temperature with the presence of hæmorrhages in the skin and from the mucous membranes and an unusual amount of jaundice. No

cause could be ascertained for the onset of this rapidly fatal disease, the etiology of which is still unknown.

M. M—, aged ten months, was first seen on Monday, Feb. 23rd, 1891. The family history was good, except that a sister and brother of the father had died of phtthisis. The mother had always had good health although she was a thin and weakly-looking woman with little colour. This was the eighth child; she had lost only one previously. The child had always been considered healthy, but had had a slight attack of bronchitis two months ago. The infant, a fine, healthy-looking child, was suffering from jaundice, which had been noticed by the parents the day before (Sunday). Up to that time she had been in good health. There had been some slight vomiting on Sunday, but nothing serious enough to make the parents uneasy. On examination the child appeared remarkably fine for its age and was well nourished, but suffering from well-marked jaundice, the conjunctivæ being more markedly stained than the skin. There had been some slight vomiting the day before, but none since. The tongue was slightly coated; the bowels had been opened the previous day, the motion being soft and of a pipe-clay colour; pulse and temperature normal; abdomen normal; lungs and heart normal. On Tuesday (the 24th) the jaundice had increased in intensity, and there was some hæmorrhage from the gums, the blood being particularly dark in colour; several petechiæ were observed on the back. The edge of the liver could be made out well under the ribs, and the area of hepatic dulness was diminished. The skin was cool and dry; temperature normal. The pulse varied in frequency. No vomiting. Only a very small quantity of urine (about one drachm) was obtainable, which was of a yellow colour with a greenish-yellow sediment. A play of colours was obtained with nitric acid. The child was evidently worse, and inclined to be restless. The next day the jaundice was still more marked; the child was considerably worse, and very drowsy. The bowels had not acted. The tongue was black, there was considerable hæmorrhage from the gums, and dark blood was issuing from the mouth and nose. Besides the petechial spots on the back there were now several on the arms and legs. The temperature was subnormal and the liver dulness appeared less. No vomiting. The child rapidly sank, and died in the afternoon. During the attack the pulse varied considerably, being usually over 100 per minute. The highest was 120, the lowest 60, per minute. The head symptoms were not marked. There was some slight restlessness at the commencement of the attack and drowsiness towards the end. The treatment at first consisted in large doses of sulphate of magnesia and carbonate of magnesia. On the Tuesday five grains of mercury with chalk were given. The bowels only acted once after the child was taken ill; this, no doubt, was partly due to the fact that the parents neglected to give the medicine regularly.

*Necropsy, eighteen hours after death.*—A well-nourished child with marked jaundice. There were six large extravasations of blood on the back, from about the size of half a crown to a four-shilling piece. There were fifteen small spots on the left leg, two on the right leg, two on the left arm and seven on the right arm. These were from about the size of a threepenny piece to a sixpence. The heart and lungs were normal. The liver was well under the ribs and very small slightly wrinkled and flabby. The wrinkling increased a few hours after removal. The gall-bladder contained a small quantity of light-coloured fluid. There was no obstruction in the ducts. The lobules were obliterated. Weight seven ounces. The spleen weighed one ounce and a half. There was a small supplementary spleen. The right and left kidney weighed one ounce and three-quarters each. The heart weighed an ounce and a half. The stomach and intestines contained a fair amount of blood, and there were slight extravasations into the coats of the intestines. The large intestine contained hard grey fæces. Other organs were normal in appearance. Mr. Shattock examined a specimen of the liver microscopically and reported thus: "The sections show no trace of hepatic tissue, but simply granular detritus. I should consider it certainly an example of acute yellow atrophy."

*Microscopic appearance of the blood.*—The red corpuscles were very granular and irregular, and showed no tendency to form rouleaux. The white blood cells were greatly increased in number. There were crystals of tyrosine and cholesterine.

*Remarks by Mr. STANLEY YEOMAN.*—This case I consider shows in a remarkable manner the close similarity that subsists between phosphorus poisoning and acute yellow atrophy of the liver, a similarity that has led some to

suggest that the two are identical. In arriving at the diagnosis a careful exclusion of the possibility of phosphorus poisoning was perhaps the most important evidence. This was carefully confirmed at the post-mortem examination, since there was not even a minute trace of phosphorus in the stomach or intestines. Another point in the case was the absence of vomiting, which is so characteristic of phosphorus poisoning. On the other hand, the cerebral symptoms were not so marked as might have been expected. One of the most interesting points noticed during life was the remarkable variation in frequency of the pulse. The temperature, nevertheless, never rose above the normal. Considering the readiness with which the temperature rises in children from slight causes, this was well worth noting. Unfortunately, a fair specimen of the urine could never be obtained for careful examination. Finally, I may say that the extremely rapid change in the hepatic tissue, the quick termination of the case, the absence of vomiting, the unlikelihood of a child of that age obtaining phosphorus, and the rarity of phosphorus poisoning, all negative the idea of any foul play. Dr. Philip very kindly attended the case throughout with me, and I have to thank him for many of the above notes, which, unfortunately, I feel are far from complete, as the circumstances surrounding the patient considerably handicapped us.

### GOONA HOSPITAL, INDIA.

#### ABSCESS OF THE LIVER; OPERATION; RECOVERY.

(Under the care of Surgeon-Captain SHAW.)

THE following case illustrates the treatment of hepatic abscess by direct incision and drainage from the side through the abdominal wall, adhesions having taken place between the apposed surfaces of peritoneum. It has been stated by Kartulis that the pus of hepatic abscesses following the dysentery of hot countries does not contain micro-organisms, and that therefore, should any escape into the peritoneal cavity during operation, peritonitis is not likely to ensue. It is almost impossible to exclude dysentery as a cause of the abscess, for not infrequently, although there has been no history or symptoms of that disease in fatal cases, it has been found that dysenteric ulceration of the bowel was present.

L. C.—, aged thirty-four, was admitted on April 19th in a feeble and emaciated condition with the following history. Eighteen months before admission he had a severe attack of fever (malarial) lasting three months. He completely recovered, excepting that after meals he was troubled by a sense of weight and uneasiness in the gastric and hepatic regions. Some months afterwards, whilst kneading his abdomen, he noticed a swelling over the liver, and there was slight pain. More than a year elapsed when the pain became so severe that he was obliged to come into the hospital for treatment. He had never had dysentery or syphilis. His condition on admission was as follows:—Very thin, emaciated, and so weak that he could not sit up in bed; pulse 120 and thready; severe constipation, with scanty clay-coloured stools; tongue flabby and pale, except where discoloured with dark patches; complexion muddy looking. No vomiting or cough had troubled him at any time; no purulent matter had been passed per anum. The hepatic dulness reached downwards to the level of the umbilicus, but was not increased upwards. The enlargement was wholly confined to the right lobe. The patient complained of severe headache, and his temperature rose every evening to 100° or 101°. He was ordered a purgative and some "hepatic mixture," with quinine. A severe burning pain in the liver was eased for the time by a blister. Some days later the assistant surgeon tapped a very distinct bulging just below the ninth rib, drawing off twenty-four ounces of pus, and thereby giving much relief.

May 6th.—Again tapped, thirty-two ounces of pus being drawn off.

10th.—Tapped; twenty ounces taken out.

12th.—Eleven ounces more drawn off, making a total of eighty-seven ounces evacuated by the trocar.

After this the pus continued to ooze out of the trocar openings, until the patient was seen by Surgeon-Captain Shaw on May 17th. He was then terribly pulled down, could not sleep, but had no night sweats. The skin over the liver was tense and red and was bulged out, but fluctuation was absent. The pus discharged was very foul. Over the base of the right lung rough friction sounds and small

crepitations were heard, but there was no dulness. As no opening had established itself between the liver abscess and the intestinal canal or the lung, and as the pus would force a passage for itself sooner or later, it was determined to drain the cavity. A probe put into one of the trocar openings followed a sinus running subcutaneously upwards and backwards for three inches and a half. Under chloroform the abscess cavity was explored through one of the openings just below the ninth cartilage, which was about four inches and a half long, two inches and a half broad, and ran obliquely backwards and inwards; its mouth was about one-third of an inch in diameter. A three-inch incision was made parallel to and just below the thoracic margin. The peritoneum was adherent to the abdominal wall; one small vessel was tied, and the necrosed tip of the ninth cartilage, which lay close to the opening, was snipped off. With the operator's finger the walls of the cavity were felt to be ragged and slimy, and about six or eight ounces of chocolate-coloured pus gushed out, mixed with what looked like lumps of white fibrin and with large blood-clots. The cavity was then washed out with 1 in 4000 sublimate solution, half an ounce of iodoform and strips of lint soaked in iodoform emulsion put in, and finally a large drainage-tube and dry dressing, which completed the procedure. Speed was imperative owing to the critical condition of the man. His temperature rose that evening from 97.6° to 100.8°.

21st (the day after the operation).—Morning temperature normal, evening 102.2°; pain much less. A little pus was syringed out of a small recess, which was opened into by the probe. There was no foul smell. The remainder of the case can be shortly stated. For two days after this the temperature rose to 101.2° and 99.8° in the evening, being normal in the morning. The cavity was syringed out daily, the discharge soon ceased, but the drainage-tube and strips of lint were kept in, chiefly to prevent the mouth from closing. Surgeon-Captain Shaw is of opinion now that they might have been removed long before they were. The tube was shortened as the cavity got shallower and narrower. The man himself frequently took out the tube when the surgeon's back was turned and persisted in squatting on his "hunkers" to eat his meals. Thinking himself quite well he left the hospital on the night of June 9th, but was taken back next day none the worse for his exertions.

June 18th.—Tube removed; cavity almost filled up. Liver dulness quite normal and base of right lung quite clear of adventitious sounds. The man has got quite stout. There is now only a very small opening left, through which a little serous discharge comes. He is about to return to his field work in a few days. He will have been about eighty days under treatment.

*Remarks by Surgeon-Captain SHAW.*—There is nothing definite to point to the exact cause of the disease. The frequency with which the pus had to be drawn off shows how quickly it accumulates in these abscesses and, what is more important, shows, I think, how likely any incomplete measure, such as tapping or aspiration, is to prove a failure. In my opinion waste of time and tissue might have been saved in this case by early incision and drainage. I do not quite understand why the opening of a liver abscess externally below the ribs should be looked on with so much alarm, for, I should suppose, peritoneal adhesions are almost certain to have had time to form.

**HULL ROYAL INFIRMARY.**—The chairman and managing committee of the Hull Infirmary have received a communication from Messrs. Reckitt, in which the writers express their intention of presenting the Withersna hotel and grounds to the hospital as a convalescent home. The authorities, in acknowledging the generous gift, express their sense of the benefit the donation will confer on the sick poor of the neighbourhood.

**THE NEW HOSPITAL AT HALIFAX.**—After some delay the work of erecting the new infirmary seems to have entered a more satisfactory phase. A site, fourteen acres in extent, has been purchased, and the subscriptions already promised, along with the proceeds of the sale of the old infirmary, will, it is believed, be sufficient to cover the cost of the new hospital. The scheme formulated at the outset provides for from 130 to 150 beds, and it is proposed to build an administrative department on a scale sufficient for a hospital of 300 beds should funds be available for that extension.

## Notices of Books.

*How to feel the Pulse and what to feel in it: Practical Hints for Beginners.* By WILLIAM EWART, M.D. Cantab., F.R.C.P. London: Baillière, Tindall and Cox. 1892.—*Die Untersuchung des Pulses, und ihre Ergebnisse in Gesunden und Kranken Zuständen.* Von Dr. M. v. FREY. Berlin: Julius Springer. 1892.—The study of the pulse is as old as medicine itself, and in the two works named above we possess as complete a view of the subject as is possible; but the standpoint of the English and of the German author is very different. Dr. Ewart confines himself strictly to the limits imposed by the title of his book; Dr. Frey aims at presenting a complete physiological exposition of the mechanism of the circulation as regards the heart beat and the pulse wave. The one is of immediate utility in daily practice; the other shows us how far science has succeeded in elucidating the various phenomena of cardiac action in health and disease. Each work has its special value and the one complements the other. Dr. Ewart's little work, although addressed to beginners, will be read with pleasure by older men who have been feeling pulses all their lives. In systematic arrangement of matter, in minute attention to detail, in taking nothing for granted but explaining each point as it arises, the book is a model clinical manual. Opening with a description of the methods of feeling the pulse, and then considering briefly the essential facts of its physiology, the author describes in turn the qualities and varieties of the normal pulse, and then the abnormal conditions. A short chapter is devoted to capillary pulsation and another to venous pulsation. There is a very useful glossary of terms employed in the description of the pulse, and a list of Latin terms appended to the volume. We doubt if anyone could find fault with a book written with such laudable intent and so admirably adapted for its purpose, whilst to the student it must be invaluable. Dr. Frey's more ambitious monograph dismisses in a few pages the information to be gained by the time-honoured method of palpation. He is more concerned with describing the sphygmograph and its congeners, which have been devised to record not only the character of the pulse wave but the degree of tension and the volume of the pulse. The cardiac movements are studied very thoroughly, both as regards the pressure conditions and the cardiographic record. The arterial pulse is then studied as to its characters in different regions, and the separate variations it undergoes under varied circumstances. In a word, the book represents the advanced physiology of the time, whilst its value is enhanced by the ample bibliography appended to each chapter.

*Diseases of the Nervous System.* By J. A. ORMEROD, M.D. London: J. & A. Churchill.—This is the latest addition to Messrs. Churchill's Students' Guide Series. In the execution of such a work, novelty and originality are not to be expected, or even desired; but an author who sets before himself the object which Dr. Ormerod had in view must possess a wide and intimate knowledge of nervous disease, an intuitive perception of the difficulties which a student is likely to meet amid the intricate problems of neurology, and at the same time the ability to describe in clear and precise language the various phenomena of the different diseases. The author of the work before us evidently possesses all those requisites in an eminent degree, and he is to be congratulated on the judicious use which he has made of his knowledge and wide experience. The book is divided into eight chapters; the first two are devoted to an account of the anatomy, normal and morbid, of the nervous system; the third, fourth and fifth treat of the symptoms, general and special, of nervous

disease; the sixth, of diseases of the nerves and cord; the seventh, of cerebral diseases; and the eighth of functional diseases. In some parts the work is necessarily sketchy, but on the whole it is admirably fitted for the purpose for which it is intended.

*The Surgical Diseases and Injuries of the Stomach and Intestines.* By F. BOWREMAN JESSETT, F.R.C.S., Surgeon to the Cancer Hospital. London: Baillière, Tindall and Cox. 1892.—The title chosen for this little book is not a very happy one. It should have been "The Surgical Treatment of Diseases and Injuries of the Stomach and Intestines." The investigations and writings of Senn have greatly advanced this department of operative surgery, and while it is absurd to anticipate that his work will be crowned with the same measure of success as has followed the labours of the early ovariologists, there is no doubt that a large number of cases that have been hitherto allowed to die unrelieved will in the future obtain a prolongation of life and diminution of suffering through the art of the surgeon. Mr. Jessett has repeated many of Senn's experiments, and has himself worked further on the same lines, and has tested some of the results he has obtained in animals in patients under his care. The results have certainly been encouraging. In the book before us an account is given of the work he has himself done in this department of surgery and of the work of Senn and many other surgeons in America, Great Britain and Germany. The various operations that have been suggested are described and criticised and the reader will find gathered together what has been hitherto scattered in surgical literature. It is not new material that is here given—most of it has already appeared in transactions of societies or in periodical literature, but it is very convenient to have it in book form. There is a certain amount of repetition that ought to have been avoided and in some places a little confusion between experiments on animals and operations on man. As a surgical handbook it is interesting and will be useful.

*The Mediterranean Shores of America: Southern California.* By P. C. REMONDINO, M.D. Philadelphia and London: F. A. Davis and Co. 1892.—We are quite prepared to recognise Southern California as possessing one of the best climates in the world and as an excellent sanatorium for some types of phthisis, but we confess that we feel obliged to take many of Dr. Remondino's statements with several grains of salt. For instance, he analyses the deaths from phthisis at San Diego for a period of ten years. The total number was 258. Only nine of these, we are informed, were born at San Diego, and of these eight were females. The author does not believe that these eight were true cases of tuberculosis, because (1) "the cases were attended at the end with a general breakdown, the lungs from their importance doing so (*sic*) prominently," and (2) "no one was ever infected or fell a victim to the disease by being with them." No necropsies were made. Comment is needless. Dr. Remondino is fond of classical allusions, but either he is often at fault or his printer has been unkind to him. In "Eulesis" it is a little difficult to recognise the seat of the Eleusinian mysteries and "Dionysius" is not the Greek equivalent of Bacchus.

*Our Temperaments: their Study and their Teaching.* By ALEXANDER STEWART, F.R.C.S. Edin. Second Edition. Crosby Lockwood and Son. 1892.—This work, the first edition of which was favourably noticed in these columns, is an attempt to throw light on one of the most obscure, but assuredly most interesting, chapters in anthropology. The author has accumulated a mass of information from philosophers, medical men, poets, artists and others to prove the existence of recognisable types or temperaments

and urges that practical lessons of great importance may be drawn from his conclusions. For ourselves we should deny the existence of even the four leading so-called temperaments—viz., the sanguine, the bilious, the lymphatic and the nervous—or rather we should maintain that the existence of intermediate types is so universal as to deprive this classification of practical value. Nevertheless, there is truth mixed up with much doubtful theory in the speculations that have been made on the question of temperaments, and anyone anxious to look into the subject will find much to interest and instruct him in Mr. Stewart's pages. The illustrations, printing &c. of the work are excellent.

*The Rationale of Mesmerism.* By A. P. SINNETT. Kegan Paul, Trench, Trübner and Co. 1892.—Mr. Sinnett is very severe on those who have questioned the right of Mesmer to be regarded as a great thinker and discoverer, and maintains that "the records of mesmerism, both early and recent, teem with illustrations of the way in which magnetic influence from a distance has been successfully exerted upon persons quite unprepared to receive it." It is strange that the men most qualified by training and ability to establish a new scientific fact still remain quite incredulous regarding the existence of this "magnetic influence," while freely admitting the reality of the phenomena of hypnotism. It is the explanation of the phenomena that is the disputable point. Mr. Sinnett has, of course, his *argumentum ad hominem* ready for all who question his special creed. "The incredulity of unspiritual mankind is Nature's own protection against those unfit as yet to use her higher gifts." The book is in fact an attempt to revive the belief in animal magnetism as the explanation of the mesmeric or hypnotic trance and the well-known attendant phenomena. We regard that theory as decisively disproved and see little advantage in reviving an obsolete controversy. Hypnotism is a curious chapter in psychology and, although hitherto practically barren, may yet prove helpful to mental science, if not to therapeutics. But we feel sure that "animal magnetism" in the strict sense is a chimera.

*Zwölf Vorlesungen über den Bau der nervösen Centralorgane.* Von Dr. LUDWIG EDINGER. Dritte umgearbeitete Auflage. Leipzig: F. C. W. Vogel. 1892.—It is only a few months since we had the pleasure of welcoming the appearance of an English edition of Dr. Edinger's well-known lectures on the anatomy of the central nervous system. The high appreciation which the work enjoys in Germany is evidenced by the appearance of a third edition in which the author has made valuable additions to the letterpress and also to the illustrations. The book in its present form furnishes one of the most complete and reliable accounts of the structure of the nervous system which we possess, and the publication of an edition which incorporates all the latest knowledge in this department of research is an event of interest and importance.

*Handbook for Travellers in Northern Italy.* Sixteenth Edition; carefully revised, with a Travelling Map and numerous Plans of Towns. London: John Murray. 1892.—The tourist season and the autumn months will find many of our compatriots at the Italian lakes and in the chief cities of the subalpine and Lombardo-Venetian provinces. For them there is no better guide than the time-honoured "Murray," brought up as it is to the latest and most trustworthy information. The present edition, however, is less strong in some departments than it might be—notably in that of the mineral-watering places and health resorts. Abano, for instance, and Battaglia, both in the Venetian territory, while receiving ample justice as regards their hotel accommodation and local attractions, are quite inadequately dealt with in respect of their mineral waters.

*Yellow Fever: a Monograph.* By JAMES W. MARTIN, M.D. Edinburgh: E. & S. Livingstone. 1892.—Although the essay on which this monograph was founded formed a paper "read before the Royal Medical Society of Edinburgh some years ago," it is by no means old-fashioned in its treatment of the subject. Besides giving a very clear and concise account of the chief facts about yellow fever and its congeners among the malarial fevers of the tropics, it discusses its etiology at some length. The author seems to be favourably impressed with the results reported by Dr. Freire of his treatment by inoculation, and ventures to predict that medical science "in the near future" will do much to deprive this scourge of the tropics of its terrors. We sincerely trust that his prophecy may be verified.

*Differentiation in Rheumatic Diseases (So-called).* By HUGH LANE, L.R.C.P., M.R.C.S. Second Edition. London: J. & A. Churchill. 1892.—We need merely note the appearance of a second edition of this little book, the substance of which originally appeared in these columns. It is written in a purely practical spirit and points out with success the leading features of chronic rheumatism, rheumatoid arthritis and gout, besides discussing with commendable detail the main lines of treatment of a class of painful affections which so often defy our powers in this direction. The plan of thermal treatment in the baths of Bath is stated and judicious hints given as to their prescription.

*Nervous Exhaustion.* By WALTER TYRRELL, M.R.C.S. London: Kegan Paul, Trench, Trübner and Co.—It is a pity that Mr. Tyrrell should have applied this title to his little book. Nervous exhaustion is now so generally used as a synonym for neurasthenia, which is daily becoming a more definite clinical entity, that it is a pity to complicate matters by embracing under the title such diseases as epilepsy, hysteria, neuralgia and "suppressed gout," whatever that may be. The author holds that these conditions are all the result of the exhaustion of what he calls "nervous force," and his treatment is directed to building this up by means of tonics &c. If his pathology is correct his therapeutics are rational, but we doubt whether his theories will meet with general acceptance.

*Transactions of the Medical Society of the State of Pennsylvania.* Philadelphia: Wm. J. Dorman. 1890.—Many excellent papers are contained in this number. It would be impossible to criticise the whole of them here, but we would specially draw attention to the "Address in Hygiene" delivered by Dr. Thomas J. Mays on "The relation between Artificial Inoculation and Pulmonary Consumption," although we cannot agree with one of the sentiments expressed—namely, "that never was an *ignis fatuus* pursued which left more promises broken and greater anticipations unfulfilled than the bacillus theory, so far as it stands related to the prevention and treatment of pulmonary consumption." Interesting also are the papers on "The Management of Obstinate Dropsies," by Dr. James Dyson, and "Prolapsus of the Rectum in Children," by Dr. K. R. Wharton. As a chronicle of local epidemics and diseases the reports from various county societies are worthy of note.

*The Veterinary Journal.* August 1892. Edited by GEORGE FLEMING, C.B., LL.D., F.R.C.V.S. London: Baillière, Tindall and Cox.—The articles in this number are of full average interest, and comprise, amongst others, a description by Mr. J. Clarke, F.R.C.V.S., of a disease in cattle commonly called grass disease, which seems to have hitherto escaped distinct notice. A paper by Veterinary-Captain J. A. Nunn, F.R.C.V.S., on the use of Cocaine in Masking Lameness, is also worthy of perusal. An editorial article in this number deals with a subject which is now exciting considerable attention—namely, the prevalence of glanders. The editor suggests that recourse might be had to mallein as an aid to diagnosis in this disease.

## Analytical Records.

### COMPRESSED PELLETS OF CASCARA SAGRADA AND OF PEPSINE.

(WYLEY'S, LIMITED, COVENTRY.)

AN examination of both these preparations proved very satisfactory. The contents of the compressed pellets of pepsine were, on experiment, shown to be remarkably active on coagulated albumen, rapid digestion ensuing, the liquid subsequently exhibiting the reactions for peptones. We regard the pepsine pellets, therefore, as a suitable and elegant form of digestive. On examining the cascara pellets they were found to dissolve gradually in cold water until a brown mass of extract was exposed which was not entirely soluble in water, but almost completely in spirit. Seeing that the pellets contain all the desirable ingredients of the "sacred bark" they are calculated to serve a useful purpose, and are especially adapted for the administration of this drug to those who in other forms find it unpleasant to take. Both pellets are coated with pure cane sugar.

### TRITICUMINA FOOD AND BREAD.

(MEABY'S TRITICUMINA COMPANY, READING.)

The preparation of these farinaceous foods is evidently based on sound scientific reasoning. Triticumina is described as a wheaten food malted under conditions specially ascertained for the purpose of rendering the product most suitable for use as a digestible food. This statement is borne out by our analyses, which elicited that the food contains twice as much soluble carbohydrate as ordinary wheaten flour, while it was particularly rich in valuable phosphatic constituents, the total mineral matter amounting to 1.32 per cent. This proportion of valuable mineral constituents is doubtless secured by the use of the entire wheat in its preparation. The specimen of bread made from this flour is an excellent brown loaf of uniform texture, having a sweet nutty smell on fracture and keeping moist and fresh several days. The microscope showed the presence of branny particles, but so small in size as to be hardly distinguishable by the unaided eye. We have not examined a better specimen of bread or one that approaches more closely to the ideal.

### DORINA BISCUITS.

(H. B. CHIBNALL, 77 AND 79, KING-STREET, W.)

These biscuits, which more nearly resemble cakes, are suitable for invalids because they contain a high percentage of soluble carbohydrates, a suitable proportion of fat and a corresponding quantity of mineral salts, including soluble phosphates. They make an excellent sop when prepared with milk in the manner directed, and being largely soluble little effort is required to masticate them. They contain more phosphate than ordinary bread and an increased amount of dextrin and maltose. The microscope shows wheaten starch cells, which have undergone certain changes consequent on well-regulated cooking. The biscuits, no doubt, possess distinct nutritive value.

### LIQUOR PAPAIN ET ACID GLYCERINE: PAPAIN TABLETS AND LOZENGES, &c. (DR. FINCKLER AND CO.)

(B. KÜHN, 36, ST. MARY-AT-HILL, E.C.)

The action of papain, or, as it may be called, vegetable pepsine, very closely resembles that of ordinary pepsine, inasmuch as it not only dissolves fibrin but converts it into true peptone. Moreover, papain possesses a distinct advantage over pepsine in that it is equally active in acid, neutral, or alkaline menstrua, so that there is every probability that it is effective as a digestive agent throughout the whole alimentary tract. True papain is obtained from the juice of the trunk and fruit of the carica papaya by treating it with alcohol, which precipitates the ferment. So obtained it is quite uniform in its action. The papain forming the basis of the above

excellent preparations is evidently prepared in this way. The digestive action of this curious substance is admirably demonstrated when the above glycerine extract is used for experiment. It is seen to rapidly digest white of egg when warmed to blood heat with a little water in a test tube. The lozenges, tablets and pilules afford very convenient forms for the administration of this valuable digestive, and in view of the important advantages papain possesses it is deserving of more extended trial.

### SUN-CURED VIRGINIA CIGARETTES, ALL TOBACCO.

(T. P. & R. GOODBODY, LONDON AND DUBLIN.)

In a report of THE LANCET Analytical Commission,<sup>1</sup> which was instituted in consequence of prevailing rumours that the tobacco in cigarettes contained opium, and other injurious substances, the analytical evidence showed that there was no foundation for such suspicions, the only possible thing that could be objected to being the copper lettering used on the paper wrapper to indicate the brand. As was then pointed out, if the lettering containing copper were objected to, no doubt manufacturers could be induced to adopt some other means of indicating or distinguishing their own particular wares. Recently<sup>2</sup> it was reported from America that deaths had actually occurred from the excessive smoking of cigarettes, the paper wrappers of which were stated to contain arsenic and phosphorus. We are inclined to doubt whether either phosphorus or arsenic has ever been found in the paper used for cigarette making, unless in exceedingly minute and therefore negligible quantity. None of these charges, at any rate, can be brought against cigarettes when the tobacco contained in them is wrapped in nothing but pure tobacco leaf. Cigarettes have been submitted to us by the above firm made in this way. We have not obtained a tittle of evidence that they contained anything but pure tobacco. The only alkaloid detected in the cigarettes when they were suitably treated was the one normal to tobacco—viz., nicotine; search for substances of an injurious nature procured only negative results. When smoked they compare very favourably with the ordinary cigarette; they were cool and sweet and appeared to burn more slowly.

### CANADIAN CLUB WHISKY.

(WALKER AND SONS, ONTARIO, CANADA; LONDON OFFICE, 18, COCKSPUR-STREET, TRAFALGAR-SQUARE, S.W.)

This whisky will not suit all palates, inasmuch as it is strongly impregnated with the peculiar and somewhat aromatic flavour of the wood in which probably it has been stored. It is very dark in colour, but in spite of this it is particularly soft to the palate, having been allowed to mature, according to Excise guarantee, for a period of five years. It blends well with aerated waters. Analysis showed the presence of a slight excess of tannin and extractive matters, but in other respects the results were quite normal. Absolute alcohol 42.50 per cent. by weight, 50 per cent. by volume, equal to 87.60 per cent. proof spirit; extractives, 0.21 per cent. The sample was quite free from all raw and injurious products.

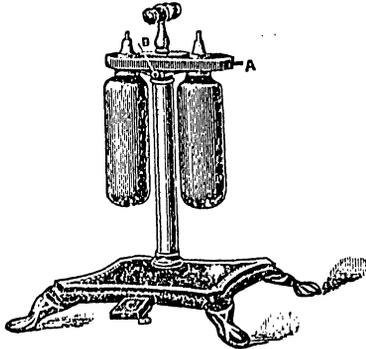

## New Invention.

### THE PEDAL LEVER GAS STAND.

THE various forms of apparatus in ordinary use for the administration of nitrous oxide gas possess some disadvantages, which become especially apparent when it is desired to give the gas for an operation lasting some minutes. Until recently the choice of apparatus has been restricted to the gasometer arrangement or some form of metal bottle with a screw foot-

<sup>1</sup> Vide THE LANCET, Oct. 20th, 1888, p. 785.  
<sup>2</sup> Vide THE LANCET, April 2nd, 1892, p. 709.

key. In the former the holder is generally too small and requires refilling from the metal bottle during the operation, while in the latter the screw arrangement invariably in use is not the mechanism best adapted for easy manipulation by the foot. It is often difficult to turn on and off, and the bottles are held in the horizontal position. To do away with these disadvantages Mr. Walter Smithard, L.D.S., has invented the apparatus figured below. The stand consists of a hori-

A, Screw for clamping bottles to valves. B, Aperture for indiarubber tube conveying gas to bag. C, Pedal.

zontal base 12 in. in diameter, raised by four feet 2 in. from the ground. In the centre of the base is fixed an iron tube cased with brass. In the upper end of this pillar and in the pillar itself are arrayed the valves and springs, and projecting from the side of the base is the pedal (c). The bottles are fixed to the valves in the upper end of the pillar and held in position by a powerful screw clamp, and the gas is turned on at each bottle. The apparatus is then ready for use, and requires only the slightest pressure of the foot on the pedal to liberate the gas into the bag as it may be required. It possesses the following advantages. The stand will carry any sized bottle from a fifty gallon steel to a hundred gallon iron. The bottles are held in the upright position, which facilitates the easy and regular escape of the gas. When the bottles are once fixed and turned on, the slightest pressure of the foot on the pedal liberates the gas into the bag. There is no turning the foot round or slipping of the key, the supply of gas is under perfect control with a minimum of trouble, leaving both hands and the whole attention of the administrator to be devoted to the patient. This apparatus has been in use at the hospital for some months, and has been found most convenient, compact and easy to work.

ALEXANDER WILSON, F.R.C.S.,  
Administrator of Anæsthetics, Victoria Dental  
Hospital, Manchester.

## GRAVES' OR BASEDOW'S DISEASE IN ANIMALS.

THE morbid condition with which the names of Graves and Basedow are associated is not very rare in mankind, but it is only recently that an affection closely allied to, if not identical with, it has been observed in animals. In man, as is well known, goitre is frequently accompanied by exophthalmos and cardiac disturbance, and indeed it is these three symptoms which constitute the characteristics of Graves' disease. In later years we find mention now and again in veterinary literature of cases of goitre in different species of the domesticated animals, but until 1888 the malady under consideration was not reported as having been observed in them. In the *Archives of Veterinary Medicine*, published at St. Petersburg in that year, Jeswjenko describes the case of a four-years old thoroughbred horse which, after a long gallop, exhibited abnormally strong and frequent arterial pulsations, cardiac palpitations, and progressive weakness; it had tumefaction of the thyroid body, and in sixteen days there was very marked double exophthalmos, the ocular globes being so protruded that the eyelids could no longer cover them. The animal died in about a month. The same observer had witnessed a somewhat similar case in a small pet bitch aged seven years, but it was cured in three months on being treated with iodine. In the annual veterinary report for the kingdom of Saxony for 1890 Roder alludes to a cow which had severe

palpitation of the heart, frequent and violent arterial pulsations, a thyroid body hypertrophied to the size of a man's fist and very intense double exophthalmos. This condition had been in existence for four years. Another instance—the best hitherto described—was brought before a meeting of the Paris Central Society of Veterinary Medicine not long ago by Professor Cadiot of the Alfort Veterinary School. This case was that of a horse (gelding) about fifteen years old, which had been taken to the school as a patient. The owner had been in possession of it for only six weeks and knew nothing of its history, but he had noticed that it was gradually becoming feebler. On examination the animal was found to be emaciated, very weak and apparently exhausted, with a swollen and painful fore-limb and œdematous infiltration into the dependent parts of the body, as well as several small tumours in various regions. At the upper and front part of the neck, on the trachea, was a hard and indolent hemispherical tumour adhering to the inner surface of the skin, which appeared to be constituted by hypertrophy of the left thyroid body; situated on the left side of the trachea, it advanced to the middle line. On the right side there was only slight enlargement. A very striking symptom was noted on the course of the superficial arteries; this consisted of very strong and perfectly rhythmical movements of the skin over these vessels, similar to those occurring in certain cases of aortic insufficiency; when the hand was placed over these arteries, bounding pulsations could be felt. These phenomena were more especially observed over the course of the glosso-facial, temporo-maxillary, posterior auricular, occipito-muscular, carotid and gluteal arteries. On each side of the croup and over the course of the latter vessel sudden jerkings of the skin and subjacent muscular layer were remarked at equal intervals—powerful pulsations synchronous with the cardiac systole. At the glosso-facial artery the pulse numbered from seventy to eighty beats per minute, and on compressing the superficial veins they assumed large dimensions. When the hand was applied to the præcordial region violent, precipitous and palpitating shocks were perceived, which, as it were, shook the thoracic wall. Auscultation also revealed serious cardiac disturbance, mainly marked by violent contractions of the heart which appeared to cause the animal pain. Rectal exploration of the posterior aorta and its terminal vessels gave evidence of their increased dimensions and abnormal pulsations. Inspiration was normal, but expiration was interrupted. The temperature was 38.4° C. The urine did not contain either albumen or sugar. The visible mucous membranes were slightly infiltrated, and an examination of the blood gave no reason for suspecting the existence of leucæmia. The symptoms increased in intensity and the thyroid body augmented in size until death ensued in three days after admission to the hospital. A necropsy showed the heart to be hypertrophied; it weighed seven kilogrammes; there were insignificant valvular alterations; the large arteries had an enormous calibre—they were about double their ordinary diameter—but their walls were thin; all the viscera were congested; the left thyroid body was more than ten times its natural size, measuring twenty-three centimetres in circumference and nine in diameter, and had a very vascular and fibrous aspect; it was surrounded by a thick capsule of connective tissue; there was only slight hypertrophy of the right thyroid body. In this case, related by Cadiot, one of the characteristic signs of Graves' disease—exophthalmos—was absent; but the others—cardiac palpitations, bounding pulse and hypertrophy of the thyroid—were certainly present. The absence of abnormal prominence of the eyeballs in this horse rather militates against the supposition that it was the malady in question; but then, as Cadiot pointed out, even in mankind all the symptoms enumerated are not equally conspicuous in every case, the goitre or the exophthalmos may at first be trifling and only become noticeable at a late period and successively, or be altogether absent. What predominate in this syndrome are the circulatory troubles, which appear to be dependent on an obscure lesion of the sympathetic nervous system or of the vaso-motor centres; and if it generally assumes a typical form easy to recognise, it also appears in masked or abortive forms which render diagnosis difficult. In this case it was admitted that there was something more than a mere coincidence between the cardio-vascular disturbance and the hypertrophy of the thyroid body, and that it had at least a close relationship to Graves' or Basedow's disease, of the existence of which in animals the instances recorded leave scarcely any room for doubt.

# THE LANCET.

LONDON: SATURDAY, AUGUST 20, 1892.

THE Tables (which are specially compiled for THE LANCET, and which we publish monthly) giving an analysis of statistics of sickness and mortality in London may be consulted with great advantage by our readers. They indicate not only the number of deaths from the principal infectious diseases, but the number of notifications of cases of such diseases for all the London districts. To be forewarned is to be forearmed, and to know that certain diseases are abroad is a stimulus to early and correct diagnosis. Such Tables, too, are a valuable guide to the health of different districts, and should afford comfort or dissatisfaction to the sanitary authorities according as their record of health is good or otherwise.

They are useful to us to-day as showing at a glance the importance of a much-despised complaint in the list of the causes of summer mortality. It cannot be too often pointed out that the diseases which cause the largest number of deaths are frequently those which are least feared. The following is a list of the "deaths from principal infectious diseases" that occurred in London during July in numerical order: diarrhœa, 627; measles, 300; diphtheria, 129; whooping-cough, 100; scarlet fever, 88; enteric fever, 25; small-pox, 4; typhus fever, 2; other continued fevers, 2.

Our more particular purpose just now is to invite attention to "diarrhœa," which is classed among the zymotic diseases and stands at the head in prevalence and mortality at the present season. In any summer it would be right to emphasise this disease and its lessons, but it is especially so at a moment when the invasion of Eastern Europe by cholera excites anxiety. So far as cholera is concerned we may be comforted by the better knowledge of the laws of the diffusion of the disease and the better powers of sanitary authorities for resisting it. But the more we study allied diseases and learn to effectually cope with them the greater confidence may we feel in contemplating the invasion of a disease which admits of so little satisfactory treatment. Our Tables show that, whereas the mortality in June from diarrhœa in London was 200, that of July rose to 627. It is satisfactory to know that, large as is this number, it falls short of the average by 298. This may be set down to some extent to the comparative moderation of summer heat, and to the general improvement in public health due to the development of sanitary legislation and the greater diffusion of sanitary knowledge. Be this as it may, we are in the very height of the season for such disease. The temperature of the earth is at 56.5°, which Dr. BALLARD has ascertained to be the temperature at which the disease prevails, and any study of it is opportune. It may be premised that most of the mortality from diarrhœa is among infants. "Choleraic diarrhœa" jeopardising life in adults is relatively rare, and probably much rarer than it used to be in England. The older members of the profession will remember that it used to be not uncommon to see very severe cases of "English cholera" in this country with evacuations that

produced collapse and sometimes suppression of urine. Even in a healthy season diarrhœa still causes in London in one month 627 deaths. The pathology of these cases has always been more or less obscure. The older authors used to say that in many of the cases the necropsies revealed no lesions, and that the flux was a merely functional one attended with no change of structure. Of late years the accounts of the morbid anatomy have been more definite and serious. In cases that are without inflammatory symptoms, severe and yet not fatal, it is probable that there is some turgescence of the intestinal glands. The glands are more distinct than usual. Dr. J. LEWIS SMITH of New York, to whom we owe good descriptions—clinical and anatomical—of infantile diarrhœa, says the solitary follicles of the large intestines especially are in most cases elevated and their central depression distinct; the patches of PEYER are also prominent. In the graver cases, attended with pyrexia and lasting a week or more, serious lesions are found, and the disease is a genuine enteritis. Dr. SMITH says: "The 1500 cases of so-called cholera infantum, reported every summer in this city, are, with now and then an exception, cases of inflammation generally protracted." He adds the following suggestive sentence: "In like manner the excess of reported cases of infantile marasmus in the second half of the year over those reported in the first half should be added to the statistics of intestinal inflammation." He made eighty-one post-mortem examinations of such cases, and remarks that the lesions he found resembled those described by BILLARD, who says: "In 80 cases of inflammation of the intestines that I examined with great care there were 30 of entero-colitis, 36 of enteritis, and 14 of colitis." Dr. EMMETT HOLT, an American physician, found that in his experience infantile diarrhœal diseases were associated with distinct lesions. Of fifty-seven such necropsies follicular ulceration existed in nineteen, or 33 per cent., and in almost every case the solitary follicles were very much enlarged. The extreme heat of American summers, the indifferent sanitation of American cities, and the lax and excessive feeding of American children, account for the great prevalence of this disease in America as well as for the amount of thoughtful study it has there evoked. The great thing for a practitioner to do in regard to any case of infantile diarrhœa is to ascertain whether it is of the simple or inflammatory order. The temperature should be carefully taken. In young children it is best taken in the rectum. If persistent pyrexia be present together with emaciation after profuse vomiting and purging in young infants the case should be regarded as serious; but in many cases, even though of inflammatory origin, the temperature may be subnormal and the appearance may indicate collapse. The causes of such attacks are chiefly high temperatures of the air and earth, improper or unsound or excessive food, chills, and insanitary environment. To enumerate the chief causes of such a serious disease is to indicate its chief remedies, which must consist in moderation of heat, with flannel bandaging of the abdomen; in food, the nearest to that of mother's milk; in the removal of everything unhealthy in the dwelling, or of the child from the crowded city, where such diseases are most fatal, to the seaside or a country air. The feeding is often the

most difficult problem, and must be worked out in each case. In some cases with persistent vomiting it is well to suspend milk for a time and substitute barley water. The milk used should be perfectly fresh and sweet, and it is often safest to use it boiled. A mixture of barley water and milk, with or without a little lime water, is frequently beneficial, but in severe cases meat juice, from scraped raw beef, with a little glycerinum boracis, will often give satisfactory results. A linseed poultice on the abdomen is often signally useful. Medicines play a secondary part, but they have their uses. Purgatives are rarely necessary, owing to the excessive evacuations with which we have to deal, while opium has to be used with very great caution. A few drops of brandy in food are often beneficial. All sorts of drugs have been recommended, but the simpler sort are the best, and probably few are more useful than a teaspoonful or two of chalk mixture, with a few grains of bismuth. The individual judgment of the practitioner in each case, formed in the light of ascertained facts of causation and pathology and guided by previous thoughtful consideration and experience in dealing with infants, is, however, the sheet anchor of safety in the treatment of a disease which is so frequently full of danger.

THE powerful articles on the future water-supply of London which have lately appeared in *The Times* are, we are glad to find, in perfect accord with the views so often stated in these pages. The writer, evidently no friend to the London County Council, yet agrees that the London County Council alone, or in coöperation with the City authorities, must undertake the control of the future supply. He holds that in London "our county councillors, our School Board representatives, our guardians and so forth are sheer products of the influence of the wire-pullers upon the gullible and ignorant voter." Yet he urges that the metropolitan water-supply must either be entrusted to this Council or to a vaguely defined analogous body. It is somewhat premature to discuss the question now while it is under the consideration of a Royal Commission, but it is our plain duty to repeat and emphasise the remarks which we made when this body was appointed not many months ago. The considerations involved are complex, but may be ranged under three heads—viz., sanitation, justice and economy. Each would require a volume for its complete consideration: all that can be offered here is an imperfect synopsis. First, as to the sanitary aspect of the case. For more than twenty years we have urged that the present metropolitan water-supply is unsatisfactory in quality. Whatever care may be used in the protection of the sources of supply, danger of accidental and serious pollution must always exist when the supply is drawn from rivers flowing through populous districts. We have repeatedly pointed out the dangers to which the Upper Thames is exposed; and, although at ordinary times no ill effects can be traced to such pollution, any zymotic epidemic might render the danger urgent. Filtration is at present our only safeguard, and the value of efficient filtration has been abundantly shown by modern bacteriological research. But, to say the least, it would be premature to assert that the most careful sand filtration would render water that had recently been polluted with the cholera or typhoid bacillus safe as a London water-supply.

Secondary to, but hardly less important than, the quality of the future supply is its quantity. The development of London in late years has been so gigantic that it is not possible to form any accurate judgment in regard to its future extension. Upon any reasonable estimate the requirements of the metropolis will soon be greatly in excess of its water-supply. Very little more water can be drawn either from the Thames or the Lea, and supplementary contributions from deep wells are problematical not only as to quantity but also as to their possible effect upon local centres, a consideration which leads us to the second of our headings.

Justice in regard to water-supply must be considered from two points of view. First, existing rights must be respected. Anything approaching to confiscation of money fairly invested, not only by original speculators but by *bona-fide* investors, would be repudiated by the conscience of the country. We know by experience that the price paid when property is acquired by compulsory purchase is always in excess of the real value, and this is in accordance with strict equity. Extravagant over-payment is unjust to the public, but under-payment or very mean payment is unjust to thousands of individuals. We may be sure that in the future, as for the most part in the past, these opposite errors will be avoided. Justice to local centres outside the metropolis must also be carefully observed. To denude another town or even a village of its water-supply without reparation would be manifest injustice, and the avoidance of this injustice is probably the gravest difficulty which the Royal Commissioners have to face.

With the economic considerations involved in this great question we have no immediate concern. They are for the statesman rather than the man of science. Every friend to his country will admit that the blessing of a free supply of pure water, obtained without interference with the rights of others, is worth purchasing even at a high price. Most people are by this time convinced, as we have long been, that a great ultimate economy, and no extravagant outlay, will follow the adoption of a wise reformation in our London water-supply. As for the future sources of supply which are still open to us, we must for the present, for lack of space, reserve our opinion.

THE article on "The Art of Dining" which appears in the current number of the *Nineteenth Century* from the pen of Colonel KENNEX-HERBERT contains many hints not only interesting from the social point of view, but also important dietetically. The proper choice, preparation and serving of food is not a matter to be handed over to gourmets or gluttons, or to be regarded as merely interesting from the æsthetic and gastronomic point of view. It is in reality a national question of the very first magnitude, touching the public health in one direction, the public purse in another, and not indirectly affecting the well-being and happiness of every rank and every individual. National food customs, on the one hand, reflect and, on the other, to a material degree influence national character. They are the growth of ages, and are largely affected by questions of race and climate. Hence sudden and thoroughgoing reforms are not to be expected, and are hardly desirable. Still it is wholesome to have our national failings in this regard indicated, and to have lines

of possible development and amendment pointed out. It can hardly be said that our national record in the matter of *cuisine* is a good one. Few are the foreign authorities which have ever been found to praise British cookery, and, with all our national self-complacence, we do not select this topic as one on which we can justifiably plume ourselves. Yet those who have travelled most will be the readiest to agree that on one point we probably excel the civilised world—viz., attention to the quality of meat. It may be questioned whether any beef or mutton quite equals that of the British islands, and assuredly, with all our failures in the gastronomic art, no other people are so careful to secure the fineness of quality and condition of the meat brought to the tables of the wealthy and well-to-do. This deserves to be remembered when our errors and defects are under review.

Colonel KENNEY-HERBERT treats mainly of the formal or elaborate dinner, and finds much to condemn in the profuse and ostentatious style now widely prevailing amongst us. He is for simplicity, and lays down as sufficient for all purposes the following *menu*:—A soup, a piece of fish, a *relevé*, an *entrée*, a roast bird, an *entremet de légume*, a sweet *entremet*, a savoury morsel and dessert. The important point in this arrangement is the place of the *relevé* after the fish and before the *entrée*. There can be little doubt that, contrary to current custom, this is the natural order of things. The *relevé* is the principal item in the repast and should not be later than third on the list. The diner begins with soup, because, if wearied by fatigue or long fasting, nothing is so quickly absorbed or so readily excites the digestive powers as a small quantity of warm meat essence, such as are the best soups. Fish follows, not of necessity, but because it is a light and wholesome article of diet, which from its comparative absence of flavour could not be relished after the more savoury meats. At this point it is obvious that the principal item of the meal should be served, and the interpolation of a trumpety *entrée* is (if we carefully interpret our needs) really an obviously unnatural arrangement. On the other hand, when the appetite has been fairly satisfied with the substantial *relevé*, there is much to be said for following it with a delicate and attractive *entrée*. The roast fowl, vegetables, sweets and dessert seem, on the whole, a natural arrangement, which it would be impossible to alter for the better. The course composed simply of vegetables is almost always found on the Continent, and may be made one of the most attractive and wholesome features of the meal.

The writer makes merry, and not without cause, regarding the curiosities of nomenclature presented by the orthodox bill of fare. He relates how on one occasion whitebait was announced as *à la Madras*. "Happening to know something of the Southern Indian capital I waited for a new experience, for as they have no whitebait they have no special way of serving it there; when lo! the small fry appeared plentifully besprinkled with raw curry powder... No sane person uses curry powder in the form of pepper in the land of Ind." The writer's strictures might extend further in the same department. The phraseology of the ordinary *menu* is more frequently than not a hideous hotch-potch of French and English, a meaningless jumble of arbitrary and often ill-chosen terms. We would not plead for reducing the *menu* to pure Anglo-Saxon, for it must be admitted that for many indispensable terms that language

furnishes no equivalent for the French terms in ordinary use. Such words as *entrée*, *entremet*, *relevé*, *fricandeau*, *macédoine*, *soufflé*—to mention a few out of many—have no satisfactory equivalents in English, and we seem obliged to borrow from our neighbours, whose culinary genius has so manifestly surpassed our own. But we do earnestly plead for some restriction upon the multiplication of needless and often senseless novelties in such expressions. It would surely be possible to limit the number of accepted French culinary terms and to attach to each a definite and limited meaning.

Colonel KENNEY-HERBERT condemns in strong terms the current craze for making things look pretty. "We have become the victims of a decorative mania ..... The use of fancy colours, without consideration of their congruity, for the sake of prettiness, to tint the maskings used in savoury cookery, is surely preposterous; for how in the natural order of things can a fillet of fish be green or a cutlet of chicken pink? ..... Who can see without pity in the window of some fashionable culinary professor a noble salmon that never did anyone an intentional injury put in the pillory and exhibited as a peepshow to the passer-by, with his back bristling with prawns like the 'fretful porcupine'; crayfish disporting themselves about him, his sides outraged by a gruesome tattooing of truffles and divers devices in patterns like a Maori masher, and, lastly, to complete the atrocity, an impalement of hideous 'hatchet' skewers? Surely this is as bad as the desecration of 'dead Hector' with the garish bedizenment of a circus clown." Perhaps the most revolutionary point in the article in question is the suggestion that the modern dinner should be brought to an end within an hour. This would, indeed, be a relief, but it seems too much to hope for. For the purpose of expediting the progress of the dinner the writer suggests that the various component parts of the meal should be served ready helped from the *buffet*. He also recommends the abolition of the service of cheese. There are many other points in Colonel KENNEY-HERBERT'S article which invite attention, but we advise our readers to study it for themselves. Whatever may be advanced *contra* from the social or æsthetic side the teaching of the article is thoroughly sound dietetically.

IN a striking and suggestive paper read before the recent meeting of the British Medical Association at Nottingham, Dr. A. J. HARRISON of Clifton described a new treatment for lu us, which, so far as it has at present been tried, holds out every promise of success. We have ample evidence that tuberculosis is curable. At post-mortem examinations old tuberculous nodules are frequently found at the apices of the lungs, and the investigations of Drs. KINGSTON FOWLER, SIMS WOODHEAD and SIDNEY MARTIN have shown that though some of them may still prove infectious to animals, others are completely innocuous. Hitherto, although numerous attempts have been made to cure tuberculous affections, no specific has as yet been discovered. So many failures have there been that any new announcement of a remedy for tubercle is received with scepticism, amounting almost to contempt. These feelings were greatly increased after the unfortunate fate of tuberculin. Warned by the disappointment which followed the discovery of the eminent Berlin investigator, who was forced against his own inclination and

better judgment to prematurely announce to the world the result of his labour, Dr. HARRISON was careful to avoid prediction, and confined himself to suggestion. This is a safer path, and will not detract from the merit due to the originator of a new departure in therapeutics.

The process is a strictly logical and scientific one. The germicidal action of sulphurous acid is well known, but hitherto it has only been taken advantage of for disinfecting purposes. An outbreak of tuberculosis occurred among the monkeys in the Clifton Zoological Gardens. On burning sulphur in the house further infection was stayed for a considerable period. This was the first in the series of ideas which led to a trial of the treatment now under consideration. The second was the powerful action of gases in their nascent condition. It is remarkable that more advantage has not been taken of this property in medicine. PERBIRA, in his book on *Materia Medica*, published in 1849, in speaking of the treatment of certain skin affections, refers to the use of the hyposulphite of soda to which a little sulphuric acid has been added; but for the purpose of destroying germs *in situ* it has never before been used. The first part of Dr. HARRISON'S process consists in saturating the affected tissues with a solution of hyposulphite of soda, forty grains to the ounce, and then applying a lotion consisting of five drops of strong hydrochloric acid to the ounce of water. An improvement in the patient's condition is speedily noticed, islets of healthy scar tissue first making their appearance. The process of healing rapidly extends, producing a healing surface unequalled by any that has yet been obtained by other methods, except perhaps after frequent scrapings; but there is no loss of substance. Some ten cases have been thus treated, all with satisfactory results. One case, which was exhibited at Nottingham, was so advanced that operative measures were out of the question, but after six months' treatment a series of healthy scars is now all that remains. In some of the cases the treatment was purposely suspended for two months, before all the lupoid tissue had disappeared. At the end of this period there were no signs whatsoever of any breaking down in the scar, and even the lupoid tissue which remained was contracting, as if the pabulum upon which the germs fed had been rendered unsuitable for their further extension. This was especially marked in one case, where previously there had been an ulcerated surface the size of a five-shilling piece. With the exception of three small points this had entirely healed and only a healthy white scar remained.

Logically there would appear to be no reason why this treatment should not be equally beneficial in cases of phthisis, although the difficulty of satisfactorily causing vapours to penetrate deeply into the lung is well known. Indeed, Dr. HARRISON has under his care one case in which sprays of the two solutions were used with marked decrease of physical signs and symptoms and considerable improvement in the general condition. It remains to be seen, of course, how long the improvement already noticed will continue, but the result in lupus affords encouragement for further trial of this treatment by other competent observers.

Our report of the proceedings of the meeting of the British Medical Association at Nottingham may fitly be supplemented

by a word of congratulation on the success of the symposium dedicated to the discussion and promotion of medical missions. THE LANCET, as its readers are well aware, has taken a special interest in this development of professional activity abroad, and has from time to time drawn attention to the salutary progress it has made, particularly under the auspices of its long-established and now flourishing school at Edinburgh. Gratifying evidence was given by the speakers at Nottingham—especially by Dr. MARTYN CLARK—of the greatly enhanced proficiency of the medical missionary in the science and practice of the healing art as compared with his equipment in these essentials when the movement was still young, and further testimony not less gratifying was adduced as to the benefits that must be reaped by the profession at large through the observation and the experience of its members in regions abounding in native products as yet imperfectly analysed, and in climatic sites capable of being utilised in many disorders of the system, hæmatogenic and neurotic. In the latter respect the reports of the medical missionary in Africa, southern and even central, are full of interest, showing how anæmia and mal-nutrition can be effectively combated by residence on elevated plateaus where oxygen and sunlight combine to produce an alterative and stimulating effect highly restorative to the patient. As to the former consideration—the addition of new therapeutic agents to the pharmacopœia—the outlook for medico-missionary research is quite as promising. The civilised world has lately been celebrating the fourth centenary of the discovery of America, and in the cities—Spanish, Italian and Transatlantic—associated with the life and enterprise of Columbus, museums organised for the occasion have been rich in specimens of the medicines, from the quinine-bearing cinchonas downwards, contributed by naturalists in fields made accessible by the great explorer. What has been done in America will one day be achieved on the Dark Continent. Medical science, represented in its newly opened-up interior by missionaries professionally trained, can derive nothing but gain from its search for new products, vegetable, animal and mineral—products which may yield “weapons of proof” to the armoury of therapeutics, or combine effectively with the old for the alleviation or cure of disease. Anticipations of this kind rise irresistibly to the mental view from such related or recorded experiences as those lately heard at Nottingham, and gain outline and complexion from the contemplation of England's colonial expansion and from the honourable careers to which it invites an already amply stocked profession. Hand in hand with political advance and with the absorption of new or virgin territories under the British flag proceeds the beneficent activity of the medical mission, reclaiming the less favoured peoples of the earth to civilised life and adding fresh tributaries to the main stream of an ennobling evolution.

**UNDERPAID MEDICAL OFFICERS.**—The chairman (Mr. S. Trevail) of the Sanitary Committee of the Cornwall County Council, in a report of that committee, states that in too many instances the medical officers are inadequately paid. Parliament has constantly imposed additional work upon them without making any provision for payment of services that were not thought of when the office was created. Consequently in too many cases beneficent sanitary legislation, requiring proper supervision, has remained a dead letter.

## Annotations.

"Ne quid nimis."

### A MEDICAL MEMBER OF THE NEW MINISTRY.

WE are gratified to be able to announce that the office of Political Secretary to the Local Government Board, over which Mr. H. H. Fowler will preside, has been offered to, and accepted by, Sir Walter Foster, M.D., F.R.C.P. Lond. &c. This is the first occasion on which a member of our profession has been included in the ranks of Her Majesty's Ministry. We have long advocated the establishment of a distinct department of Public Health, and we venture to regard Sir Walter Foster's appointment as another step towards that desirable consummation. Sir Walter Foster is a representative member of our profession, and during his Parliamentary career has rendered valuable services to medicine and largely advanced the interests of the public health. We feel sure that his term of office will be marked by still further important progress in this direction. It is as yet too early to forecast what effect the change of Government may have with regard to those great health questions with which we are more immediately concerned, but the appointments of Mr. H. H. Fowler as President of the Local Government Board and of Sir Walter Foster as Secretary augur well, we feel convinced, for the future efficiency of that very important department. The advantages which will accrue to the department, the profession and the public by the post of Secretary being filled by a member of the medical profession, and especially by one so well qualified for the work as Sir Walter Foster, are so obvious that it is unnecessary for us to dilate on them at greater length on the present occasion.

### THE NEW HONOURS.

THE QUEEN has been pleased to approve the appointments, amongst others, of Professor William Henry Flower, C.B., F.R.S., F.R.C.S. Eng. &c., Director of the Natural History Museum, to a Knight Commandership of the Civil Division of the Most Honourable Order of the Bath; and of Richard Thorne Thorne, Esq., F.R.S., M.B. Lond., F.R.C.P. Lond. &c., Medical Officer of H.M. Local Government Board, to a Companionship of the same Order. This is the first occasion on which the Medical Officer of the Local Government Board has had any honour conferred on him during his tenure of office, although Sir John Simon was made a C.B. and Sir George Buchanan was knighted on the occasions of their respective retirements. In the present case the department of public health, as well as Dr. Thorne Thorne personally, receives recognition. Doubtless the honour bestowed upon Dr. Thorne is also in some measure due to the conspicuous value of his services as British delegate at the recent sitting in connexion with the Venice International Sanitary Conference at Paris, when the previous results of the Conference underwent very considerable and highly necessary modifications. We heartily congratulate Sir William Flower and Dr. Thorne Thorne on the well-merited honours which Her Majesty has been pleased to confer on them.

### CHOLERA INTELLIGENCE.

SINCE our last issue cholera has continued to spread in Russia, although the area of its diffusion has not been materially increased. The most important extension of the disease is that which is reported from St. Petersburg itself; an extension which may at any moment open up the question of the transmission of the disease by means of sea traffic between the Baltic and this country. On the 16th inst. there were 44 cases and 9 deaths in the Russian capital. Some

further extension of cholera in the central provinces of Russia has also taken place; but perhaps the most serious news from that empire is the large increase in the number of attacks and deaths which daily come under official notice. Thus whereas a week ago the fresh attacks and deaths per diem hardly exceeded some 4000 and 2000 respectively, they have now risen until they have reached some 8000 and 4000 respectively. On the 15th inst. the official records announced 8601 cases and 4288 deaths, on the 16th the numbers were 7600 and 3900 respectively, and on the 17th they were 7809 and 3742; it being at the same time announced that returns from many places were not received and hence that these numbers do not represent the total cholera in Russia. In Astrakan, at Baku, at Nijni-Novgorod, in the Transcaspian districts and even in Moscow a diminution of the epidemic has shown itself, the abatement being in some places very marked; but, on the other hand, the disease is still spreading fatally in the Don provinces, at Saratoff, Samara, Simbirsk, Orenberg and Viatka, and the province of Taurida north of the Crimea is also now an infected district. A further important extension of the epidemic is into Austria-Hungary, the province infected being Galicia. Seven cholera deaths are reported from Szkló, near Jawaroff, in the north of the province, and one such death near Kolomea in the south-east. "Cholérine" is also stated to have broken out at Lemberg. This extension is under any circumstances a matter of some gravity, but had it occurred earlier in the hot season its significance, for this year would have been even greater. From Paris the news is much more satisfactory. With the onset of cooler weather, the cholera has materially abated, and unless the rumour of its recurrence at Surcelles and at Clichy-la-Garonne turns out to have any foundation in fact, it appears practically to have subsided in France. There is, however, a serious outbreak of so-called cholérine at Havre. All along, the infection seems to have lacked much of its ordinary power for spread, and we earnestly trust that a period of immunity from the disease will now set in, and that it will be found practicable during that period to take such steps as will prevent the chance of any recrudescence next year. As we anticipated in our last issue the Local Government Board have taken some steps to prevent the importation of cholera as the result of the Russo-Jewish immigration into and across this country. The knowledge that cholera can be conveyed in bedding, linen &c., combined with the fact that these people nearly all carry with them bedding which is, to say the least, the reverse of cleanly, rendered it necessary to stop the importation of such materials, whether the emigrants reach us after travelling across Northern Germany, *via* Hamburg, or whether they come from Baltic ports. Hence the prohibitory order which has been issued as the result of Dr. Theodore Thomson's inquiries concerning this Russo-Jewish traffic in the ports of London, Grimsby and Hull.

### DEATH ON THE OPERATING TABLE.

A CASE has recently come under our notice which, if carelessly observed or vaguely reported, would probably be ascribed to the anæsthetic, but which in reality was the result of several causes, the effect of the anæsthetic probably being the least important. The patient, a weakly boy of thirteen years of age, was originally admitted into the Royal Free Hospital suffering from enlarged cervical glands; these were successfully removed and for a time he did well. Gradually, however, a swelling suggestive of a psoas abscess appeared in the left iliac region, and at the same time an exostosis developed on the knee. It was thought advisable to open the abdominal swelling, and for this purpose the patient was taken into the operating theatre on the morning of Saturday, Aug. 6th, and was anæsthetised with the A.C.E. mixture. A careful dissection was required in order to reach the abscess

cavity, which proved to be a very large one, containing between thirty-eight and forty ounces of thick creamy pus, and which was rapidly evacuated; no communication between this cavity and the abdomen or with a carious spine could be detected. The abscess was accordingly washed out, the anæsthetic withdrawn and the dressings applied. The patient was under the influence of the anæsthetic for between thirty-five and forty minutes and rather over an ounce of the mixture was administered by the semi-open method—i. e., on a sponge contained in a leather mask. The application of a rather elaborate dressing occupied about eight or ten minutes, and signs of returning consciousness became apparent; in another five minutes sickness supervened. It was then noticed that the lividity of the face was becoming more marked and that the pulse could not be felt at the wrist. The breathing continued quite regularly, but was somewhat shallow. This condition of affairs continued for about another five minutes, but gradually the breathing became more irregular and spasmodic in character, finally ceasing between twenty-five and thirty minutes after the time of the withdrawal of the anæsthetic. All possible means of resuscitation were employed, but with no result. At the post-mortem examination the heart was found to be pale, thin-walled and flabby, but beyond this the necropsy furnished no particular information as to the cause of death. The immediate cause of death in this case was undoubtedly cardiac syncope. This syncope may have been due (1) to the feeble constitutional condition of the patient; (2) to the rapid emptying of such a large abscess cavity in such a region; and (3) to the sickness which may or may not have been induced by the anæsthetic. Most probably all these causes had a share in the production of the fatal result, and certainly no particular one of them can be considered to be solely to blame.

#### THE ITALIAN TRADE IN COSMETICS AND DYES.

AT a recent sitting of the Consiglio Superiore di Sanità a list of unhealthy industries was drawn up, but a good deal of discussion had to be got over before it could be decided upon. One difficulty was that of not unduly interfering with manufacturing interests, and a very clear case of danger to the public health had to be made out before any of the industries suspected could be included in the list in question. Finally, the "catalogo" as approved was sent up for revision to the Superior Council of Agriculture and Commerce, and from that body it will return in the state in which it is intended to be put in force. Immediately connected with this discussion was the trade in perfumes and dyes, and on this the Consiglio Superiore di Sanità announced that cosmetics and tinctures used for colouring the skin and its appendages, if they contain poisons, can be sold only in compliance with the law on public health and hygiene which in terms of Article 32 prescribes certain precautions. On the phials and on the paper packets containing such cosmetics or dyes and in the advertisements of the same addressed to the public there must be indicated the quality and the quantity of whatever poisonous substances enter into their composition; on the phials and paper packets, moreover, must be put a label inscribed "poison." By this law the cosmetics and dyes in question are not withdrawn from the market, but the public are simply warned of the nature of the articles offered for sale. This is a salutary innovation on the legal disabilities affecting the chemists and druggists of Italy. It was certainly a grievance that, while they had to observe the minutest restrictions in making up small doses of poisonous substances and had to give every guarantee to the public that specialties of their own as well as medical prescriptions should duly certify the nature and amount of their contents, even when these specialties were innocuous, the vendors of cosmetics and dyes should have been allowed to ply their trade without supervision or regulation of any kind, launching on the public any quantity of such *objets de toilette*,

charged as these were with acetate of lead, with nitrate of silver and other ingredients quite as dangerous. This decision of the Consiglio Superiore di Sanità is another of the many salutary proofs of the care with which the public health of Italy is now safeguarded. In the not less important matter of foods and drinks the activity of the officers appointed to detect and expose adulteration is very reassuring. For the month of July, and in Rome alone, the seizures made by these "Vigili Sanitari" included 13,567,850 kilogrammes of articles unfit for consumption. In the same month and in the same city there were 2733 shops and storehouses visited by these officers, 1419 "confirmations" of saleable articles were made, twenty-one "specimen" samples of food were sequestered, five flagrant contraventions of the sanitary law were denounced, fifty-one local regulations were imposed, in eighty-one cases "acqua potabile" had to be laid on by proprietors of premises, and reports as to fifty-seven suspected contraveners of the law were submitted. All this must be very gratifying, not only to the English-speaking resident or visitor, but also to the Italians themselves, who have suffered far too long under abuses in the matter of their food and drink for which there is no other adjective but "scandalous."

#### CANCER "CURES."

THE announcement of an exposure by a committee of medical investigators of the Count Mattei cure for cancer is satisfactory. The faith in the alleged remedy was probably very shallow, and those who believed in it will be quite capable of disbelieving in the exposure. Evidence to those who believe in cancer "cures" by pretenders and dealers in secret remedies is very much thrown away. Even if one fraud is exposed another will quickly take its place. The fresh spurt of energy in a newspaper announcement of a provincial remedy is probably to be explained on this principle. The public in these matters is willing to be deceived. It cannot await the slow development of regular medicine. The serious thing is that both in the Mattei business and in others medical men are involved whose professional qualification gives colour to the pretension. It will be interesting to see how a certain journalist will take the Mattei exposure. The remedy was accorded a publicity by this gentleman, to which no doubt it owed a certain amount of success. Credulity is not a very safe quality in a journalist, however well meaning and benevolent; but the very least we can expect from him will be that he will give a cordial publicity to the exposure, exhibit some improvement in the critical faculty, and not lightly again lead the public into the indulgence of false hopes of impossible results from distilled water.

#### THE NEW FEVER HOSPITAL FOR LONDON.

THE proposal of the Metropolitan Asylums Board to establish a fever hospital on a site near St. Anne's-road, Tottenham, has excited the keenest opposition on the part of the surrounding inhabitants, individually, collectively and in their several corporate capacities. The Local Government Board have, however, given their consent to the scheme after receiving a report from Dr. Bridges and Mr. Hedley. The consent is subject to the following conditions:—  
(a) That no buildings for the reception of patients shall be erected except on such land as the Board may direct to be used for that purpose; and (b) that the land and buildings shall, during the twelve months next following the date of the order, be used for the reception of patients suffering from fever, and of no other patients, and at the expiration of that term shall cease to be used for the reception of patients unless the Board, by order, otherwise direct. Both the inhabitants of the district in question and the managers of the Asylums Board are placed in a very difficult position. No neighbourhood cares to have close

at hand a great fever institution, especially when it is erected for the benefit of a population other than its own. But the Metropolitan Asylums Board have a statutory duty to perform, and they have an emergency to face which the Government and the metropolis expect them to meet by some appropriate action; and when the question of these several specific fevers, other than small-pox, is concerned, they have the authority of abundant experience to show that in the case of hospitals situated in densely populated parts of London no spread of disease and no cause of ill-health result to the surrounding community if the hospital is properly administered. We cannot, therefore, blame them for their insistence on securing the site in question; neither is there any aspect of public health as to which they could have been expected to hesitate in the action they have taken. But, so far as the neighbourhood of the hospital is concerned, we fear that the limitation of the Order of the Board to one year will have but little meaning. A site once devoted to such a purpose will probably acquire a vested right to be retained for similar purposes, and, in face of the necessity of additional means of isolation for the metropolis, the prospect of an abandonment of this site after the expiration of any definite term of months is not a hopeful one for the locality. \_\_\_\_\_

#### MATERIA MEDICA IN SCOTLAND.

WE regret to find that, for the present at least, the appeal of the professors of materia medica in Scotland has been unsuccessful, and that, as the regulations now stand, students will be required to pass an examination in materia medica and therapeutics at the end of the third winter session, or at the end of the succeeding summer session. Professor Cash from Aberdeen, Professor Fraser from Edinburgh, and Professor Charteris from Glasgow lodged a formal "humble petition" against the proposed changes, and the committee appointed by the Privy Council heard counsel on their behalf. Under the new regulations it is enacted that students should attend a class of twenty-five meetings for instruction in practical pharmacy in lieu of the existing class of fifty hours of instruction in practical materia medica; that the title of the class of materia medica shall be changed to that of materia medica and therapeutics; and that the subject of materia medica and therapeutics shall be grouped along with the subjects of anatomy and physiology for the purposes of examination. The vexed question of the definitions to be assigned to materia medica, to therapeutics and also to practical pharmacy, yet remains for the decision of the professors of materia medica in the three Scotch universities. In their petition they indicated their view that practical materia medica should include not only practical pharmacy, but also "the practical study, by chemical testing and other means, of the characters of medicinal substances, in order that there may be acquired a knowledge of their chemical and physical characters sufficient to enable the student afterwards to combine these substances in prescriptions, and properly employ them in the treatment of disease." The new enactment which reduces the practical course from fifty to twenty-five classes must necessarily interfere with the efficiency of the teaching. We will not say that a great deal may not be done in a systematic course of instruction extending over twenty-five classes, but it will obviously be impossible that the same amount of detail and thoroughness can be compressed into half the time which has hitherto been devoted to this branch of study. The further contention of the professors of materia medica, that it will be difficult to teach therapeutics, with much hope of advantage, to students who have no knowledge of pathology seems also to be based upon due consideration of the students' requirements, and it is to be regretted that the committee of the Privy Council have not been able to modify the regulations in accordance

with their views. As matters stand at present, the professors will have to organise classes in practical pharmacy, but students will not be examined in this subject at any stage in their course, and they will have to teach therapeutics to students who are still working at anatomy and physiology and who have not necessarily any knowledge of morbid processes or of the pathological terms employed. The scheme appears to have been the result of undue haste, and it seems to be doomed before it has properly come into existence. There can be little doubt that after a short time of trial the scheme will require revision. If practical pharmacy is to be properly taught it must be accompanied by the stimulus of an examination. If the subject of therapeutics is to form an integral part of the course on materia medica, students should come to the lectures prepared by some clinical experience and by some pathological training, otherwise the lectures might almost as well be delivered in an unknown tongue. \_\_\_\_\_

#### MOSQUITOES IN FLEET-STREET.

IF only the parallel were more exact, one might appreciate in personal comfort and security the humorous contrast implied in the present visitation of London by a swarm of mosquitoes. It is suggested that these have been imported from Algeria with shipments of esparto grass for paper-making. However they have travelled, it strikes one as somewhat singular that while so many citizens with their families are enjoying a country holiday, the insect multitude has come to town, and on serious business. Unfortunately the mutual displacement is at best imperfect. A luckless residuum of mankind who must spend the season in town cannot evade the unpleasant invasion of these uninvited visitors. Untrained by custom in such matters they can but adopt haphazard, in mere self-defence, any arrangements which may most readily suggest themselves. In recent articles we have referred to some of these, and there can be no doubt that in the prospect of attentions which are always most irritating nothing could be much more appropriate than the veil, well saturated with some antiseptic. Of the value of suitable face washes we have also already spoken. Yet one other contrivance, even more easy of use because automatic, might be mentioned. This consists in the familiar practice of suspending some rather pungent antiseptic, such as carbolic acid or eucalyptus, in a vessel over a small gas jet, lamp or candle so that the fumes may impregnate the air of apartments which are all too close to accommodate both men and mosquitoes. Human endurance may well sustain the feather weight of such trifling impedimenta, and even enjoy the incense of unwonted odours when they bring deliverance from an acquaintanceship as trying as it is unhappily seasonable. \_\_\_\_\_

#### BOILED MILK AS AN ALIMENT ABROAD.

THE practice of subjecting milk to boiling heat before consumption has of late been widely adopted in European countries, whose public hygiene has hitherto been such as to counsel every means of minimising the conveyance of infection. British travellers, in Latin countries especially, will be reassured by this salutary innovation, experience having taught them that the milk supplied in hotels and pensions and added to their morning meal of tea or coffee, has too often been tainted with the micro-organisms of infectious or contagious disease, chiefly from being diluted with impure water, or, not seldom, from containing the desquamatory debris of convalescents from scarlet fever. Sanitary truth progresses slowly in those regions, and when the public health officer at length succeeded in establishing the unwelcome fact that milk was one of the surest channels by which infectious diseases were diffused, he had to encounter the objection that the boiling process to which

he insisted on its being subjected deprives it of its nutrient properties and also its digestibility. Again, however, he has been able to show that reason was on his side and that milk after boiling is not only more easily digested, but has actually a higher nutrient value than in the crude state. We allude especially to Dr. Chamouin's experiments, in which he fed a number of kittens on boiled milk and an equal number of kittens on the same milk as it came direct from the cow or the goat. Those of the former category he found to be twice again as fat and healthy as those of the latter. A kitten, however, which was left to its mother was the fattest and healthiest of all, though this was due to the assiduous attention which the maternal instinct supplied and which the experimenter pleasantly admitted was beyond the resources of the laboratory. Following up his demonstration, Dr. Chamouin examined the statistics officially issued by the Town Council of Paris as to the infantile mortality of that city, and finding that the chief cause of this was, directly or remotely, intestinal ailments, he prosecuted his researches still further, so as to include a comparison between those infants that had been fed on boiled and those that had been fed on unboiled milk. As he anticipated, he found a remarkable diminution in the death-rate of the former. His investigation was continued long enough to show that thousands of infants are annually safeguarded from intestinal disease and death by the precaution of boiling the milk on which they feed.

#### THE PREVENTION OF "OVERLAYING."

THE Registrar-General, in his last annual report, notices the fact that more than twice as many infants are suffocated by "overlying" on Saturday than on any other night in the week, and this he attributes, no doubt with perfect justice, to the intoxication of the parents during the previous waking hours. This is not the first time that a connexion between drunkenness and what, in view of obvious risks, is really a form of infanticide, has been commented on. Unfortunately the whole process of causation in respect of the latter cannot thus be explained. Even if this were possible we could hardly hope by any near or general advance of the temperance movement to reduce materially this heavy tribute of child life, but something should certainly be possible by another and more direct procedure. Rather more than a year ago, in treating of this subject, we took occasion to denounce the common custom which allows mothers and infants to occupy the same bed. We fail to see why this practice should be any longer permitted. Unless perhaps in certain exceptional cases of low infantile vitality there can be no excuse for its continuance. Over and over again it has been shown to be directly and almost inevitably accountable for a certain constant loss of infant life. Why, then, should not a young child, like any other, sleep in a separate cot? The cost of providing this is trifling. The necessity is imperative, and we see no reason why the absence of such an arrangement should not be held to be as punishable an offence as ordinary overcrowding.

#### MINUTE ANATOMY OF THE LUNG.

DR. W. S. MILLER of Clark University has done some useful work on the minute anatomy of the lung, and has thus added to the investigations previously carried out by Ewart and others. A paper by Dr. Miller is published in the *Anatomisches Anzeiger*, Nos. 7 and 8, April, 1892.<sup>1</sup> The lung was studied in various ways—by injections, corrosions and reconstructions. The last-named method was carried out as follows: For the more complex lungs the reconstruction method of Born was resorted to, by which, after the devolution

of nearly two years to a single specimen, the desired effect was produced. The lung was first prepared by making a triple injection by which the capillaries were filled with Prussian blue, the arteries with vermilion and the veins with ultramarine-blue gelatine. A single lobule was then removed, imbedded in paraffin and cut into sections twenty micro-millimetres thick. The magnifying power employed in reconstruction was one hundred, and each section was drawn on a wax plate two millimetres thick. As long as the terminal bronchus was in the section it was quite easy to locate all the air cells from section to section. Beyond the terminal bronchus the location of the bloodvessels and the shape of the air vesicles served as guides. In this way all the air cells communicating with one bronchus were drawn on wax plates and the sections carefully cut out. The framework left, when piled up, gave an exact model of the air sacs, and the pieces piled gave a "corrosion" of the same. The models were now cut in various directions in order to study the relation of the air sacs to the terminal bronchus. These studies, which were made on a dog's lung, gave the following result:—A terminal bronchus gives off a number of passages called vestibules, each opening into an expansion called the atrium. From this three or more air sac passages run to as many air sacs, which are much larger than the atria. Around the air sacs lie the air cells—to be accurate, it should be said some of the air cells, for there are others arising from the bronchi and from the atria. The air cells do not communicate directly one with another. Dr. Miller states that the walls of the atria are thin, like those of the air sacs, having a network of capillaries enclosed in them. From this it may be inferred that these parts, as well as the air cells, serve for respiration. The branches of the pulmonary artery follow the bronchi. Somewhat beyond the terminal bronchus the vessel divides into as many terminal branches as there are atria. Their ramifications cover the central side of the air sacs, the capillary network which arises from them enveloping the whole system, and emptying into veins which lie on the peripheral side. In the lobule each air sac has a vein running at right angles to the direction of the artery. For the most part the veins keep on the periphery of the lobule. Each air sac has an artery on its central and a vein on its peripheral side, with a rich capillary system between them.

#### THE ITALIAN CONGRESS OF INTERNAL MEDICINE.

ON October 25th next and on the ensuing days up to the 28th inclusive the "Società Italiana di Medicina Interna" will hold its fifth annual Congress in Rome. Its President will once more be Dr. Guido Baccelli, professor of clinical medicine at the Sapienza, and its proceedings will this year have the special interest of forming, so to speak, a prelude to the "Congresso Medico Internazionale di 1893," which, according to the Italian press, will constitute the most significant event which scientific Italy has witnessed since the revival of learning. The agenda paper for the meeting of Oct. 25th next includes three subjects of the highest importance, theoretical and practical—subjects fixed upon at the Congress of last year, and, according to the commendable Italian custom, consigned to special "relatori" (reporters), two for each subject, who have already proved themselves experts or proficient in the same. These are: (1) Inflammatory Alteration of the Cerebrum and its Treatment, by Professors L. Bianchi and F. Vizioli; (2) Climate as a Therapeutic Agent, by Professors C. Forlanini and B. Luzzatto; and (3) Rheumatic Infection, by Professors A. Riva and T. Gualdi. Besides these central themes a number of subsidiary ones will be introduced, several of which have already been announced by intending participants at the Congress, while others will be intimated to the organising committee before the 15th prox., after which no communica-

<sup>1</sup> Abstract in the Boston Medical and Surgical Journal, June 30th, 1892.

tions of the kind can be received. The terms on which the profession in Italy are invited to assist at the Congress are liberal enough to show the interest taken by the Government in its success—a ten-franc subscription entitling the subscriber to travel by railway at reduced fares and to receive a copy of the official "Atti di Congresso." Representatives of the profession from foreign countries are also, as we can testify, cordially welcomed on these occasions by their Italian brethren, and British practitioners or consultants whose autumnal holiday may find them in Rome during the last week of October would find much to interest and gratify them in the proceedings of the Congress. With this view, applications for tickets of membership should be made to Dr. Edoardo Maragliano, professor of clinical medicine in the Genoese school (Via Galata, 39, Genoa), who has been commissioned by the organising committee to furnish all applicants with the required information.

#### LAVATORIES AT RAILWAY STATIONS.

ANYTHING that seriously affects the comfort of the larger half of the English people can hardly be a matter of trivial consequence, and this is of course the more true if the health of so many persons is at the same time involved. Such a matter is public lavatory accommodation, respecting which complaints have recently been heard that due provision has not been made for the larger—that is, the female—section of the community. A lady writes to us objecting to the penny tax imposed on those of her sex who make use of this form of convenience at railway stations. We confess that we can to some extent appreciate, though we do not perhaps entirely sympathise, with her view on the subject. In so far as the needful relief of physical discomfort is concerned the railway companies are certainly bound to provide amply for it. This, we allow, is not done at most railway stations, and herein there is clearly room for improvement. At the same time it must not be forgotten that sometimes even passenger trains are fitted with needful appliance for securing a fair measure of comfort. Curiously and also culpably enough the purpose of cleanliness is apt to be more evident than its practice in this case, for many of the lavatories are by no means well kept. When, however, we come to questions of copious water-supply and the finding of well-washed linen towels we confess that the right to charge a trifle seems to us to be fully justified. The lesser, coarser, and in many ways inferior male half of the population are in this respect no more highly favoured than their feminine betters.

#### INJECTION OF MILK INTO THE VEINS.

A CORRESPONDENT writes to ask us whether the statement contained in Cope's *Natural History* of 1864 be true that "if milk be injected into a vein it will quickly become fatal, and that with more certain destruction than even the venom of the viper." Our correspondent also wants to know, if this be true, how is the danger brought about. It is not the first time these questions have been submitted to us for answer, and we admit they are difficult because the evidence is conflicting. It would seem that in some cases new milk injected into a vein undergoes coagulation and by the immediate plugging of the veins which it induces causes rapid death from mechanical arrest of the circulation. We have reason to know that this has been proved by experiment, and also that on injecting fresh milk into the peritoneal cavity of a narcotised animal, in order to ascertain if there would be absorption of the fluid from the peritoneal surface, absorption of the saline and watery part, with coagulation of the casein in rather a dense layer over the intestinal surface has been demonstrated. These facts would seem to give credence to the statement that milk cannot be safely injected into the system; but there are other experiences that

modify that view. In 1854 the late Dr. W. Bird Herapath of Bristol suggested that milk should be injected into the veins of persons in the collapse of cholera; and it is the fact that Dr. James Bovell of Toronto did inject milk in such cases in the cholera sheds of Toronto in the same year, acting independently on his own suggestion. Dr. Bovell reported on six cases in which he injected fresh cow's milk and two of the cases recovered. It was objected by ourselves and by others at the time that two cases afforded insufficient evidence of a direct advance in practice, and that the quantities of milk transfused—twelve ounces in one case and eight ounces in the other—were too small to give assurance of positive results apart from other influences that were at work and that would account for the recoveries. At the same time the experiences proved that there are circumstances under which milk can be injected into the venous circuit without danger, and that one of those circumstances is a condition when this remedial measure is most demanded and most promising. For the moment we may leave the matter with two suggestions—namely, that the danger which may result from the presence of milk in the veins is not septic, but is from coagulation of the milk and the plugging arising therefrom; and that if this danger could be prevented very important results might be obtainable from transfusion of milk in collapse of the choleraic type.

#### FUNCTIONAL NERVOUS DISEASES.

DR. W. H. THOMSON of New York recently read a paper before the Association of American Physicians on the above subject. An abstract is given in the *Boston Medical and Surgical Journal* of June 30th. The term "functional" has been applied in general to nervous diseases in which no characteristic organic changes have yet been demonstrated. Most writers, however, regard the term as only provisional, on the assumption that some kind of structural change in nervous matter must underlie every definite nervous disorder and that such change will in time be found. Dr. Thomson has long been of opinion that there are intermittent nervous disorders which cannot be explained by any hypothesis of changes in nervous matter, whether molecular or otherwise, but are to be explained by the varied states of the blood. By a proper selection of functional poisons some close imitations of functional neuroses can be artificially induced and cause neuralgia, paralysis, delirium, convulsions and all intermittent symptoms of the kind, and then it is noted that these symptoms disappear in about the time and order that the functional nervous attacks decline. Another correspondence between functional poisons and functional neuroses is that in both pathological anatomy affords no assistance in the explanation of the results. Modern chemistry has shown that in the healthiest processes of our digestion a whole series of poisons are elaborated which are of the same nature as the functional poisons with which we have been long familiar, and are quite sufficient to cause every variety of functional nervous derangement and even to kill, without the microscope or scalpel being able to tell why. Against the perils of auto-infection the system is provided with a variety of safeguards. One of the most efficient seems to be the antiseptic properties of the digestive secretions, which keep the putrefactive processes in the alimentary canal in check. The liver also subserves a preservative function against auto-infection. But the complex chemistry of these secretions is liable to numerous disturbing influences, notably nervous irritations. If nervous influences are capable of deranging the chemistry of the body, why may not such perturbances of nervous origin, occurring now and then as nervous actions characteristically do, suffice to produce either increased amounts of alkaloidal poisons or else to diminish the effectiveness of the normal

antidotal processes? These considerations seem to offer us a hint of the explanation of the intermittency in functional neuroses. The bearing of this view on treatment is as follows: First, instead of vaguely expecting help from structural anatomy to show him the pathology and treatment of this difficult class of diseases, and meanwhile choosing his remedies according to the old empirical methods, the physician should look for aid from the knowledge of the chemistry of diet; second, gastro-intestinal antiseptics should be studied as a particular branch of therapeutics. Lastly, the investigation of leucemias, of which lithemic states are an example, is of equal importance in a great variety of morbid states with functional disturbances. Directed by these three principles, suggested by the progress of organic chemistry, Dr. Thomson thinks that the treatment of functional diseases would be much more effectual than if we continue to seek for mere drugs with specific properties or to wait fruitlessly the verdict of pathological anatomy.

#### THE NOTIFICATION OF INFECTIOUS DISEASE.

DR. RAYNER D. BATTEN, of Campden Hill, has been fined at the West London Police Court for not sending a notice or certificate to the medical officer of health—as required by the fifth-fifth section of the Public Health (London) Act—in the case of John Weston, aged fifteen, who was suffering from diphtheria. Mr. Blanco White said the result was that for five days the premises were not disinfected. Mr. Curtis Bennett said that two notices were necessary, one for the hospital authorities and one for the medical officer of health. The medical man ought to have sent the notice himself as required by the Act. The magistrate regarded the fault of Dr. Batten as due to carelessness and not wilful negligence, and imposed a fine of only 10s. with 12s. costs. A report of the case is published in another column.

#### RUPTURE OF THE INTESTINE.

CASES of injury to the abdomen in which laparotomy has been performed for rupture of the intestine without external wound are as yet so few in number that a record of each is important. The diagnosis is usually so difficult that the surgeon hesitates to open the abdomen for fear he may be mistaken and subject the patient to what may prove to have been an unnecessary operation. Yet if the intestine be ruptured certain death will ensue without operation, and operation will probably not be of avail should it be deferred until the onset of septic peritonitis. A patient aged twenty-four was admitted to St. Thomas's Hospital on the 10th inst. suffering from the effects of a kick in the lower abdomen from a horse. He was suffering from shock, and had an anxious expression and pale face; he lay on his right side with his thighs flexed, complained of pain in the abdomen, and vomited frequently. The abdomen was excessively hard and very tender, moved very little with respiration, and on percussion was found to be quite dull over the anterior part. Urine was expelled through a catheter with some force and was quite normal. A faint bluish discolouration over the left rectus muscle indicated the part struck by the hoof of the horse. A probable rupture of intestine with rupture of omentum or mesentery was diagnosed and operation was decided on when he had rallied somewhat from the shock. About six hours after the infliction of the injury Mr. Battle performed median abdominal section, the incision extending a short distance above the umbilicus. Much blood was found in the peritoneal cavity, and there were three complete transverse ruptures of the small intestine with lacerations of the mesentery. The extent of the injuries necessitated excision of about thirteen inches of intestine with a good deal of mesentery. After

the resection there were two lesions of intestine to be united. This was done by means of Senn's bone plates; in one instance the lateral method was employed, in the other end to end. During the operation, which was necessarily a prolonged one, it was found advisable to transfuse with saline solution, and great improvement resulted. The abdomen was irrigated and drained. With the exception of some vomiting, the cause of which was not apparent, progress was good until 7 P.M. of the 15th inst., when the patient had acute pain in the abdomen, with shock and vomiting. As this was supposed to be due to the giving way of a stitch and the consequent escape of intestinal contents leading to peritonitis, the wound was opened and extended. This diagnosis unfortunately proved to be correct, and the parts which had been united end to end, gave way as the intestine was brought up to the surface. An artificial anus was rapidly formed through a new incision, the peritoneum washed out and the median wound closed, a glass drainage-tube being inserted. The patient did not rally from the shock and died at 5 A.M. of the 16th inst. At the post-mortem examination it was found that the first rupture had taken place about twelve inches from the duodenum and the second point of union was thirteen inches beyond that. The edges where the rupture had taken place looked somewhat dusky and the vitality was low—a fact not surprising when the severity of the contusion and the extensive damage to the mesentery are considered. We hope to be enabled to publish in a future issue a detailed account of the case.

#### INFLUENCE OF MIND ON BODY.

IN another column we publish an interesting and suggestive paper—a paper full of “wise saws and modern instances”—by Dr. Dale. In this is illustrated on the one hand the production of disease by psychological disturbance, and on the other the cure of what may be called morbid conditions by some profound mental effect. The efficacy of strong emotion in producing, or in helping to produce, such conditions as diabetes, chorea, and epilepsy is well recognised, and we venture to say undoubted; but it is always difficult to estimate correctly the influence of such accidents, or to say how much may be due to them and how much to an underlying instability which such a disturbance merely makes evident. That a depressed physical and mental condition also renders the bodily organs more susceptible to the influence of some poison, such as that of the specific fevers, is well recognised, and when the inseparable connexion between mind and body and the profound alterations which fear or joy bring about in, for example, secretory organs are taken into account it is not surprising that violent emotion should, as it were, open the gate to allow the admission of sundry toxic influences. It is an interesting question how much of the general—but by no means invariable—immunity which medical men enjoy from infectious disease is due to the calmness and unconcern with which they regard such diseases in relation to themselves. They forget to be afraid, and so they are clothed with an invisible and often an invulnerable cloak. The influence of mental effort in overcoming diseased conditions is not so well authenticated. The instances which Dr. Dale adduces are for the most part so-called hysterical conditions, and it is open to doubt how much such conditions have underlying them any actual change in structure. The helpless and paralysed lady who is frightened into activity by the threat of a drunken man to kiss her is a familiar type, but that of the man who reasoned himself out of an attack of hydrophobia is not so common, and would certainly require careful looking into. Of the efficacy of music and the “influence of sweet sounds” in producing that feeling of restfulness and comfort which is so conducive to recovery from any morbid state

Dr. Dale has a high opinion, but he enters a judicious *caveat* against allowing it to assume the garb of quackery or mystery. The consideration of the whole matter leads to an eminently rational view of the duty of the physician in relation to the mental attitude of the patient. That duty is to instil by means of faith and hope a courage which will enable him to bravely resist his foes, and Dr. Dale is of opinion that nothing more than this is to be expected from the influence of the mind in the removal of bodily diseases.

#### PROSECUTION FOR FALSE CERTIFICATE OF DEATH.

WE regret to have to record that another practitioner has been proceeded against for giving a certificate of death in a case which he had not personally seen, but which had been attended by an unqualified person. The defendant was Mr. Stephen Francis Smith, L.S.A., of Seven Sisters-road, Holloway. The offence was admitted and even regretted. An attempt was made to represent it as an inadvertent and not a wilfully misleading act, but the magistrate of North London Police-court (Mr. Haden Corser) fined the defendant £10 and £3 3s. costs, or twenty-one days' imprisonment. The prosecution was conducted by Mr. Charles Townley, superintendent registrar of Islington. Dr. A. G. Bateman, honorary secretary of the Medical Defence Union, attended and watched the case on behalf of that body.

#### FUNCTIONS OF THE CORD.

IN the summer number of *Brain* Dr. Mott gives the result of observations and experiments he has made with the view of discovering the relations and functions of especially the ascending antero-lateral tract, commonly known as Gowers' tract in the spinal cord. In summarising his results he states that the peripheral portion of the anterior and lateral columns consists in great part of ascending and descending cerebellar fibres. The former, the ascending, may be divided into a ventral and dorsal portion, and these should be named the ventral and dorsal ascending cerebellar tract instead of the antero-lateral and direct cerebellar tracts, the latter being the names by which they are now generally known. The ventral portion, it is said, may be completely divided in monkeys apparently without producing analgesia. The ascending cerebellar tract, he says, forms a connecting bridge between the superior vermis of the cerebellum and cells in the cord, the dorsal portion connecting the cells of Clarke's column with the dorsal part of the superior vermis, while the ventral portion connects certain cells of the cord with the ventral part of the superior vermis. Section of the antero-lateral column was found to produce much denser degeneration amidst the arciform fibres than could be accounted for by the slight injury to the direct cerebellar fibres. The extensive tract of degeneration corresponding to Gowers' antero-lateral tract (which he thinks, with Löwenthal, should be called ventral cerebellar) has been traced in the monkey to the superior vermis by way of the superior cerebellar peduncle, forming in its course a curious loop over the fifth nerve.

#### DUST, UPHOLSTERY AND DISEASE.

HOUSEHOLDERS in furnishing would do well to remember that the ordinary practice of covering a floor with carpet is not without its disadvantages, even its dangers. The particles which give substance to the pure search light of a sun-beam as it penetrates the window pane are of the most varied character. Harmless as are very many of them, there are also many more possessed of true morbid energy and capable of almost unlimited multiplication. Anyone can see therefore how, when sheltered in dusty woollen hangings, chair upholstery and carpets, they render these articles veritable harbours of disease. The less we have of such the better, especially in bedrooms. Some practical deductions naturally

suggest themselves. As to curtains and carpets, it is but rational that they should, as a rule, consist of the smoother and harder fabrics which will bear thorough and frequent brushing. If thicker floorcloths and rugs be used, they should be such in size and arrangement that they can be readily taken up and beaten. It is but part of the same argument to say that as much of the floor as possible should be either varnished or laid with oilcloth, so as to allow of frequent cleansing. Cane and leather, for a like reason, are incomparably superior to the richest upholstery when we come to speak of general furniture. Some, perhaps, may imagine that in making these observations we treat this matter too much as a hobby. Only one circumstance, however, is required in order to convince any such of their real and practical significance, and that is the actual presence of infectious disease. When this appears all forms of cumbrous comfort in the apartment must give place not merely to a freer and simpler arrangement, but even to bare, sunlit, and airy desolation.

#### HYDROCHLORATE OF PHENOCOLL.

HYDROCHLORATE OF PHENOCOLL has, since its introduction, been known to have a certain influence in fever, rheumatism and neuralgia and to favour the elimination of nitrogen. To define this influence more exactly a series of experiments was made in Professor Eichhorst's clinic in Zurich by Dr. P. Balzer, who published the result of these experiments in the *Therapeutische Monatshefte* of last June. The hydrochlorate of phenocoll did not produce any dangerous symptoms or any disagreeable effects in any of the cases experimented on, except in two patients who suffered from cyanosis, though the remedy was administered in daily doses of a drachm or a drachm and a half. In doses of fifteen grains it is a good and speedily acting antipyretic, but not preferable to phenacetin or antipyrin. In proportion to its antipyretic effect, the pulse generally becomes slower, but not in a corresponding ratio to the decline of temperature. In the large doses above mentioned it is an effective anti-rheumatic remedy, and may be administered when salicylic acid is contraindicated. It also acts beneficially in those cases of neuralgia which have their origin in sudden cold. Phenocoll increases considerably the elimination of nitrogen in health, but does not seem to influence the rhythm of the pulse in any way.

#### THE TREATMENT OF ANGINA PECTORIS.

ANGINA PECTORIS and arterial sclerosis are two very common diseases in Russia. This statistical connexion is hardly surprising when it is considered that the former affection is probably due to sclerosis of the coronary arteries of the heart. The severe and prolonged paroxysms of angina pectoris may be explained by the presence of a thrombus or embolus in these arteries. Dr. Kernig, who gave a lecture on the treatment of angina pectoris before the Medical Association of St. Petersburg, which was published by the *St. Petersburg Medicinische Wochenschrift*, speaks of two cases in which the post-mortem examination confirmed the above-mentioned opinion of the etiology of the affection. In both cases sudden death had followed a severe paroxysm, and a well-defined softening of the cardiac muscle, with incipient demarcation of the focus of disease, was present. This view of the causation of the paroxysms is supported by a clinical observation which Dr. Kernig made—namely, that in some cases, in a few days after the paroxysm, pericarditic symptoms were observed, which might be understood as proving that the centre of softening had reached the pericardium. Consistently with this belief, he enjoins absolute rest for about two weeks after an attack, so as to favour the cicatrization of the softening centre in the cardiac muscle. This absolute rest

must be maintained even when the patient feels quite well after the paroxysm and has a good pulse. He is, nevertheless, always in great danger immediately after the attack; but with complete rest and prudent avoidance of all unnecessary exertion of the heart he may escape this danger, which will be passed when the softened cardiac muscle has cicatrised. Dr. Kernig treated several extremely grave cases according to this rule without a single relapse, though one of the patients had remained for four years under observation. Patients must be particularly careful at such times, when from previous experience a paroxysm may be expected. Walking in heavy clothes must be absolutely avoided. With the first symptom of an approaching attack the sufferer must rest immediately, and if possible assume the recumbent position. When the attack occurs in the street the patient must immediately be removed to his home and should certainly not attempt to continue walking. At the same time Dr. Kernig does not fail to appreciate the value of regular and rational exercise when no fresh attack is imminent and sufficient rest has been taken after the last paroxysm.

#### COMPULSORY SANITARY WORKS.

THE Local Government Board are taking proceedings under Section 299 of the Public Health Act, 1875, to compel Worcester so to deal with its sewage as no longer to contaminate the river Severn. The city had been given a definite time in which to carry out the necessary works; nothing had been done in the matter, and now application has been made to the Court of Queen's Bench for a rule nisi for a *mandamus* to compel the Corporation to carry out the order of the Local Government Board. A similar rule was asked for against the Corporation of Rochester, but oddly enough it was limited to the village of Borstal. Why this comparatively insignificant and outlying part of the city has been selected for the exercise of compulsory powers it is a little difficult to understand. We have shown what is the state of Rochester city with its liquid filth soaking away into multitudinous cess-pools, and the place has become notorious for its maintained default in regard to sewerage. The city as such is left out and Borstal alone is attacked. It may be that the lives of the prisoners and of those who are under Government control at Borstal are regarded as of especial importance in Government circles; but the general public are hardly likely to look upon any such differentiation in the same light.

#### PSEUDO-BULBAR PARALYSIS.

IN the inaugural dissertation of Dr. Max Anderlya is related at length a case of this character. A brief account of it is given in the last number of the *Neurologische Centralblatt*. The patient was a joiner who had enjoyed good health until he was forty. At that age he had an attack in which the power of one side (he could not remember which) was impaired and he had some difficulty in moving his tongue and in articulating. He soon regained the lost power and was practically as well as before. Nine years later he had a sudden attack, losing power in his right side and experiencing a good deal of difficulty in swallowing. He improved very much, but the right arm and leg remained permanently weak. Two years later he lost power in his left side and he had considerable difficulty in talking and also in swallowing. A year after this last attack he was admitted into the hospital and he was then found to be very weak on the right side and almost completely powerless on the left. He also had much difficulty in swallowing; articulation was difficult and was nasal in character. The reflexes were present. There was loss of sensibility on the left side and the patient was unable to move his eyes to the left of the middle line. The fundi were normal. His condition remained the same as regards power; he wandered a little during the day, rather more during the night; the respiration became of the Cheyne-Stokes variety and he died

eight days after admission. A careful and thorough examination, both at the time and after the specimen had been preserved, revealed a condition of softening in the right lenticular nucleus and internal capsule and a somewhat atrophied condition of the right frontal lobe. A similar but smaller area of softening existed in the left lenticular nucleus, while the medulla, pons and cord appeared normal, except for some descending change in the right pyramidal tract. The kidneys were granular and the heart dilated. The case is an interesting one and forms a valuable addition to a now well-recognised variety of paralysis in which the symptoms closely resembling those of ordinary bulbar paralysis are due to a lesion on each side of the cerebrum.

#### TABES DORSALIS AND SYPHILIS.

IN a recent number of the *Berliner Klinische Wochenschrift* Professor Erb gave additional support to his well-known views in regard to the close connexion between tabes dorsalis and syphilis. These again have lately been called in question by Professor Leyden, and now an abstract of Professor Erb's reply appears in the *Neurologische Centralblatt*. Professor Leyden had called in question the reliability of Professor Erb's statistical proofs, but to this the latter retorts that if in a number of patients suffering from certain conditions 80 to 90 per cent. of those are found to have suffered from syphilis, while in a similar number suffering from other diseases only 20 per cent. have had syphilis, there seems to be good ground for postulating a causal connexion between the two conditions. Professor Leyden's second objection is the inefficacy of anti-syphilitic remedies in tabes dorsalis, but to this Professor Erb's answer is that the success of such drugs is not necessary in order to establish a diagnosis of syphilis, and that there are many cases of tertiary syphilis affecting the brain and spinal cord in which mercury and iodide of potassium are quite inefficacious. Professor Leyden's third point is the dissimilarity of the morbid anatomy in cases of tabes dorsalis and tertiary syphilis, but, as Professor Erb points out, it is a matter of extreme difficulty, even impossibility, to say in such cases what is syphilitic and what is not in the various morbid conditions found; and he finally concludes by expressing the opinion that in the great majority of cases of tabes dorsalis there is a distinct causal connexion between that condition and syphilis.

#### REJECTION OF NOTIFICATION AT NEWTON-ABBOTT.

AT the recent meeting of the Newton-Abbott rural sanitary authority, which, on the advice of the medical officer of health, declined to adopt the Infectious Diseases (Notification) Act, 1889, some very remarkable arguments were used and statements made. One of these statements had reference to the number of cases of scarlet fever passing without medical attendance. The medical officer of health said that in that district three-fourths of the cases have no medical attendance. He said that, in an experience of nineteen years, in which he had seen scarlet fever in farm-houses and dairies in the large and populous district of 180 square miles, no instance had occurred of the conveyance of the disease. Does it not strike him that as cases are not reported and not even attended by medical men such an experience cannot go for much or be set against the positive contrary experience of others. The argument of some of the speakers was that the Notification Act was preferred to the Act of 1890 because notification involved a small fee to the medical men. This is a gross and rude misrepresentation. We must confess our surprise at the attitude of the medical officer in dwelling on the fact that his authority would have to pay fifteen shillings for notifying six cases of the disease in one family, and generally that the disease was so mild in the county as to be beyond recognition and almost beneath notice. Does it not occur to him that under

an efficient system of notification, in which the *parent* was made responsible for not reporting such facts, six cases would not occur in one family? We cannot believe that such representations can be finally accepted, even on the authority of a medical officer of health. Notification is a means to an end; and it is not easy to see how isolation and other measures are to be initiated until an authority has definite material for judgment.

#### FOREIGN UNIVERSITY INTELLIGENCE.

*Dorpat*.—Dr. Karl Schmidt, Professor of Chemistry and Senior Professor of the Physico-mathematical Faculty, is about to retire. He studied medicine and took his M.D. degree in Göttingen, and was for many years engaged especially in physiological research. He has also made a study of the modes of propagation of cholera.

*Freiburg (Baden)*.—Dr. Kiebel has been promoted to an Extraordinary Professorship of Anatomy.

*Halle*.—Professor Arthur von Hippel of Königsberg has been appointed to succeed Professor Alfred Graefe in the chair of Ophthalmology.

*Jena*.—Drs. Leubuscher and Ziehen have been promoted to Extraordinary Professorships.

*Naples*.—Dr. Schoelein, Professor of Physiology in Santiago, Chile, and formerly *Privat-docent* in Würzburg, has been offered the chair of Physiology.

*Toulouse*.—Dr. Herrmann, Professor of Morbid Anatomy at Lille, has been appointed Professor of General Pathology and Therapeutics.

*Würzburg*.—The chair of Chemistry vacated by Dr. Fischer, who goes to Berlin, has been offered to Professor Curtius of Kiel, but he has declined to migrate.

THE salutary *rapprochement* between Germany and Italy reacts beneficially on the latter in no direction more conspicuously than in medical education. The system of *feriencursus* (holiday courses) in clinical medicine and semiology, long in vogue in the schools of the Fatherland, is now being introduced into those of Italy—the University of Genoa having led the way in this commendable innovation. From Aug. 20th to Oct. 10th practical courses in these subjects will be given in the latter school, under the superintendence of Professors Lucatello and Devoto. All students and recently qualified medical practitioners may attend.

DR. J. S. BILLINGS of the United States Army writes to say that in the report of the proceedings of the Dublin Tercentenary he is referred to as being Surgeon General, U.S.A. The Surgeon-General of the U.S. Army is General Charles Sutherland, while Dr. Billings is simply a surgeon in the army with the rank of Major. He requests that the error should be corrected in justice to General Sutherland as well as to himself.

THE question of the extension of the Manchester Royal Infirmary having been submitted to the general body of trustees, the result of the poll has been shown to be in favour by 130 votes of the amendment of Sir William Houldsworth—namely, "That the trustees are of opinion that, whilst it is manifestly important that the infirmary should be retained on its present site in the utmost state of efficiency, any extension of accommodation thereon is very undesirable."

OPHTHALMIA in workhouse schools is often a disease difficult to deal with satisfactorily. In Liverpool it appears some difference of opinion has arisen as to the expediency of admitting to an industrial school children suffering in a slight degree from affections of the lids.

## REPORT OF The Lancet Special Commission ON SANITATION IN RELATION TO THE LAW AND PRACTICE OF HOUSE-LETTING.

NOTWITHSTANDING the enormous strides that have been made in sanitary science during recent years and the many Acts of Parliament that have been passed, and sanitary by-laws that have been framed by local authorities to secure healthy homes for the people, we have been much impressed with the difficulty constantly experienced by householders in ascertaining the sanitary history and scheme of drainage laid down in the houses which they may propose to lease and occupy from time to time. The information that has been acquired by us in our inquiry has very clearly demonstrated the reason for this anomaly; for it has proved that, with the exception of those whose work compels a knowledge of sanitation, the general public, including many landlords, affect a complete indifference to the subject,—the latter mostly from pure ignorance, the former because bitter experience in the shape of illness have never obliged them to seriously study the matter. In order to obtain the views of those best qualified to express an opinion upon this important subject as to what is or can be done under existing conditions to protect the public against insanitary homes, and what improvements (if any) in the law and practice of house-letting are desirable and should be attempted, we have submitted to 1000 house agents and surveyors in different parts of the country a series of questions for answer. Our appeal has met with a prompt and courteous response from those to whom it was addressed, and such a mass of information has been placed at our disposal and so many valuable practical suggestions put forward, that we have been able not only to appreciate the causes of the present unsatisfactory state of affairs, but also to offer for discussion some methods by which pressing evils may be remedied.

It too frequently happens that a tenant signs the agreement or lease of a house without the slightest inquiry having been made as to the drains, and such essential points as the ventilation and proper jointing of the house drain and the disconnection of waste-pipes are completely overlooked. He is not seldom imbued with the idea that "good drainage" is a variable and elastic term, and that so long as the drains are not obtrusively offensive he had better leave the matter alone. The prevalent notion that even in the minds of sanitarians uncertainty still lingers as to what points should be kept in view to render a house well drained, accounts largely, we feel sure, for the disinclination, on the one hand, of the landlord to consider carefully the drainage of his houses, and, on the other hand, for the apathy and indifference of the tenant, who usually remains passive until roused to a sense of his danger by an outbreak of illness in his home. The evidence of our correspondents goes to show that somewhat of the blame for this erroneous belief must be fixed on those who undertake the surveying of houses and the advising of tenants as to their sanitary requirements. More than one house agent has informed us that what one surveyor has assured a tenant is sanitary perfection a second has pronounced sanitary imperfection; while not a few have said that calling in a surveyor means the employment of some particular "system" of drainage. In a word, drainage is for the public a "mysterious subject." The foregoing remarks of course apply to houses which were erected before the passing either of model by-laws or Improvement Acts. Houses built after such laws have been enforced would conform to the plan required by the Act, and would therefore be drained after modern methods. But the large majority of houses now standing would be included in the category of houses erected before this date, and, as by-laws are not retrospective, would be unaffected by them, until some nuisance had been proved to exist. It is therefore desirable, if possible, to attain to some scheme of uniformity in the drainage of this class of pro-

perty, which, while not weighing too heavily upon the landlord, would enable the tenant to live in safety and comfort. We shall point out later on how we think this end may be achieved.

The points to which our inquiries have been directed are the following:—

I. Whether the information usually supplied by clients to house agents respecting the sanitary history and condition of the property they are asked to let is sufficient.

II. (a) The sort of information usually supplied; (b) the kind of information which could and should be furnished.

III. Whether the house agent was prepared to make or obtain an efficient survey of a house and its sanitary arrangements.

IV. Whether Section 12 of the Housing of the Working Classes Act, which renders it necessary that tenements to be let shall be reasonably fit for human habitation, should be extended to all houses without distinction.

V. Whether the opinions expressed on the above would apply to houses and lodgings let for short periods at seaside places and health resorts.

VI. Whether there is anything not covered by the foregoing suggestions which should be considered.

We shall now point out, first, what in our opinion are the essential conditions which should be fulfilled before the drainage of any house can be passed as satisfactory; secondly, a brief *résumé* will be given of the opinions that have been expressed under each of the first five heads; and under the sixth will be added the most important suggestions that have been put forward for the improvement of the present state of affairs; thirdly, we shall quote some of the most representative replies that have been received; and, lastly, after discussing the most important facts that have been brought into prominence, we shall explain what appear to us to be the lines to adopt for future improvement. At the end of the report will be found a table showing the numerical results of the investigation.

We should recommend that the following points be attended to in laying down the drainage of a house:—

1. As far as possible drainage should be outside the house. The soil pipe should pass directly from the closet trap through the wall and down the outside of the house to the house drain. The soil pipe should be a four-inch lead or iron pipe; its diameter should never be less than three inches.

2. The house drain should be made of glazed stoneware or iron pipes, the diameter of which is usually six inches. It should always, when possible, be carried outside the house to the sewer, but in some cases—e.g., when houses are built in terraces—this is not possible, and the drain has then to pass underneath the basement. The drain should be laid on six inches of concrete and be surrounded with it. The joints should be carefully cemented all round, so that when tested with water and smoke no leakage should occur, and oil of peppermint poured down the top closet should not be perceptible to smell anywhere along the drain. The fall should be about 1 ft. in 40 ft. and not less than 1 ft. in 50 ft.

3. Between the house and sewer there should be constructed a manhole. Into this chamber there should pass by channel pipes the house drain, rain water and waste pipes from sink, bath &c. The manhole should be kept covered with an air-tight iron lid, which it is very important to remember should be removed at intervals for the purpose of ascertaining that no obstruction exists between the house drain and sewer. It is not an uncommon thing for the stoneware syphon trap into which the channel pipes discharge to become choked and for the sewage to be backed up behind the obstruction. It is a good plan where practicable to build two manholes, one to be placed at the front of the house drain as described, and the other at the back, so that a view can be obtained of the drain along its entire length and any obstruction be readily detected.

4. Ventilation of the drain. From the house side of the manhole there should pass a vertical ventilating pipe which should open to the air above ground. The soil pipe should be carried up full bore, without bends, to a point above the roof, and end quite clear of windows and chimneys. Where two or more closets are in use and placed one above the other and opening into a common soil pipe, an anti-syphonage pipe should always be employed to prevent unsealing of traps.

5. The kind of water-closet that should be employed is a matter of opinion, "the valve," "short hopper," or "wash out" being all in use. The pan closet is now prohibited in new houses. Closets should be provided with separate

cisterns, holding from two to four gallons of water, by which they should be effectually flushed after each use. The closet should be well ventilated and have external windows.

6. The rain water pipe should be disconnected at the foot, and discharge into an open stoneware gully.

7. The waste pipes from sinks, baths and lavatories should be trapped and discharge either into channels leading to open gullies or into "heads." The overflow pipe from the cisterns should be carried into the open air, and on no account into the traps of closets.

These are the essential points, the elaboration of details and the expensiveness of fittings and materials to be employed being matters for the individual to settle for himself. We are confident that this scheme can be carried out without the incurring of exorbitant expense.

#### THE SUBJECTS OF THE INQUIRY.

I. The prevailing opinion amongst our correspondents appears very decidedly to be that the amount of information placed at their disposal by landlords for the benefit of proposing tenants is quite insufficient to enable them to give an accurate and trustworthy opinion of the houses they are asked to let or sell. The majority regard the silence of the landlords as due to ignorance, and not to the wilful suppression of defects, although some maintain that the question of sanitation is passed over on account of the ruinous expenditure which drainage alterations entail upon the landlord. In some towns, such as Leicester, Eastbourne, Brighton and Hastings, where houses are efficiently inspected by the local authority, the fullest information is obtainable, and landlords have little to gain and much to lose by the concealment of sanitary defects. Some house agents inform us that they always advise the proposing tenant to have the opinion of an independent surveyor; while one or two admit that the bare mention of sanitary defects may cause the agent the loss of his client. On the other hand, it is a significant fact when we are told that once a landlord has been compelled to put his drains in order and holds a certificate to that effect, he loses no opportunity of putting this forward as an additional attraction to his house.

II. From what we have said above it will be gathered that the sort of information doled out to agents is in the majority of cases not of a very valuable kind. In a few instances the landlord can show a plan of the drains and a certificate testifying to the good drainage of his property. In the generality of cases the agent has to be content with such statements as "drainage good," "sanitation perfect," "lived in the house many years and experienced no annoyance," "no case of illness occurred during last tenancy through the drains," "spent a lot of money lately on drains," &c. One of our correspondents informs us that he always advises the owner not to guarantee the drainage, but to say, "It is believed the drainage is good"! As regards the sort of information which should be furnished the majority declare that the landlord should be able to assure his tenant that the drainage of the house has been laid down in accordance with the scheme we have sketched above. In order that the tenant should be more completely satisfied and secured against drainage defects, we have received the following suggestions: (a) That there should be hung in the house a plan of the drainage; (b) that the landlord should produce a builder's certificate; (c) that the local authority should make periodical inspections of all houses in their district, and that certificates should be granted with date of last inspection if found in good order; (d) that the landlord should have the option of asking the local authority to make a survey of his house upon payment of a fee, that the local authority may advise what (if any) alterations should be carried out, and that if these be done to their satisfaction a certificate should be granted; (e) that plans of the drainage of each house should be kept by the local authority, which should be open to inspection on payment of a fee; (f) that the "sanitary history" of houses should be preserved by the local authority, so that the nature of the infectious diseases which have occurred in the house could be known; (g) a large number have suggested that the state of the drains should be ascertained by the tenant for himself by calling in an expert opinion, the fee for the report to be paid by the tenant.

III. As regards the surveying of houses, the majority of our correspondents have expressed themselves as perfectly competent to undertake the work, though many of them are unwilling to do so. Still the prevailing opinion is that most emphatically the survey should never be neglected before the

letting or leasing of a house. While advising the necessity for a survey, some maintain that the person to make it should not be the house agent, for the landlord being the client whose interests the agent is primarily retained to serve, an unfavourable report of the drainage may tell to his disadvantage. Again, others assert that being retained for the landlord, the agent's report of the drainage if favourable might be viewed with suspicion by the tenant, who would probably refuse to be convinced until satisfied by his own surveyor. Another objection appears to be that the house agent is disinclined to accept the responsibility of giving a definite opinion with the present uncertainty as to what constitutes "good drainage." The last and most practical objection which has been urged against the agent acting as surveyor also is that, being enlisted on the side of the landlord, he is at the same time acting on behalf of the tenant; and when the time has arrived for the agent to receive his fee, landlord and tenant have become "sicklied o'er with the pale cast of" doubt as to which of them should pay. In many cases the agent never receives a solution of the difficulty. We are informed that in Blackpool every tenant can procure a survey of his drains by application to the medical officer of health.

IV. The question as to whether Section XII. of the Housing of the Working Classes Act should be extended without distinction to all classes of dwellings is by the greater number again answered in the affirmative, although, as was to be anticipated, many hang back on account of the vagueness of the term "reasonably fit." Some would extend the provision only to houses of a rental below £40 a year, either because they consider that the rich man is well able to take care of himself, or for the simple reason that tenants of the better class prefer to be satisfied about the drainage by employing their own surveyor. A few of our correspondents think that by making the application of this section general some injustice would be done to landlords, for two reasons: (1) Because a tenant may receive a house in perfect sanitary repair, and then, maliciously destroying pipes or fittings, bring an action to recover damages from the landlord. Even in the absence of wilful damage to drains it suggests itself to the minds of some that the mere application of this section to better-class property may prove to the tenant a direct incentive to litigation; (2) because a landlord may let his house in perfect good faith, having been informed by a surveyor that the drainage was good, and then be afterwards sued for damages when defects are found out. One of our correspondents would have the Act apply to all houses except those let out to weekly tenants.

V. Opinion has been expressed with no uncertain voice that the condition in which houses and lodgings are let for short periods at seaside places and health resorts is urgently in need of reform. Nearly all are agreed that as affecting the public health of the country this is a class of property than which none is more important. We are assured by some of our correspondents that instead of being health resorts many of these houses are "veritable death-traps," and it is within the personal experience of many that the w.c. accommodation is most defective and inadequate. Some have pointed out the possibility of these houses being centres of infection unless controlled by stringent regulations. A great many agents have suggested that hotels, lodging and boarding houses should be under the control of the local authority, by whom they should be licensed, periodically examined and certificated. Others, without going the length of handing the property over to the complete control of the local authority, insist that these houses should be passed by this authority as fit for habitation, and that a certificate to this effect should be hung up in the hall or some conspicuous place. It appears that the sanitary authorities of many health resorts have already become aware of their responsibilities, and are taking active measures to ensure the safety of the public. Thus we are informed, through the courtesy of Mr. Reginald Dudfield, M.A., M.B., medical officer of health of Eastbourne, that "the corporation issues a sanitary certificate on conditions which rest with this department to decide. A draft scheme for the instruction of the sanitary inspectors and other officials has been prepared by me, but has not yet received the approval of the corporation. The building by-laws are also under consideration, and a new draft has recently been prepared. A very great improvement has been effected during the last two years in all classes of property; and the certificate being recognised by visitors as a safeguard, the number of houses fulfilling the stringent con-

ditions of the same is daily increasing." In 1890 Mr. Alderman Bray of Hastings advocated "that a system of registration on the voluntary principle be established by the Town and County Council, granting annual certificates on payment of a small fee by occupiers or owners of houses on the acquirement by the latter of a certain standard of sanitary excellence." One correspondent has objected to houses and lodgings at seaside places being brought under the same regulations as other property on the ground that the period for which these houses are let is too short and therefore visitors must take the risk!

VI. The following are amongst the most important suggestions that have been offered other than those already detailed under the preceding five sections:—(1) That all districts, urban and rural, which do not at present work under Local Improvement Acts should adopt them as soon as possible; (2) that a code of by-laws should be published by the sanitary authority as to requirements for efficient house drainage; (3) that a Bill should be passed on the same lines as the Sanitary Registration of Buildings Act introduced by Dr. Farquharson into the late Parliament; (4) that the local authority shall inspect all houses on vacation by the last tenant, the work of inspection to be carried on by the appointment of "inspectors of buildings;" (5) that the local authority shall be the sole authority to survey houses; (6) that careless laying of drains be made a punishable offence; (7) that owners letting insanitary houses be rendered liable to be sued for damages; (8) that the medical officer of health shall not be a local practitioner, and that he shall devote his whole time to the local authority and be remunerated accordingly; (9) that the work of sanitary associations shall be encouraged and extended; (10) that vestries and local authorities shall appoint qualified surveyors whose services may be available for moderate fees, as many people object to societies and associations because they believe them to be interested in pushing certain fittings and systems; (11) that schools, public and private, be inspected and reported on as regards their sanitary condition.

We here introduce the views of some of our correspondents. (The numbers refer to the questions in the circular which we sent out.)

*Messrs. Alder and Co., London.*

1. We do not consider sufficient information is given to agents on this point. It is our rule not to accept particulars for letting houses where we know the sanitary arrangements are defective. Frequently our constituents know very little on the point.

2. Information of a most superficial kind. We always feel that there is a great necessity for some independent authority to have power to inspect all sanitary appliances, whether in factories, warehouses or private residences; and that a certificate be granted only where such are in a satisfactory condition. When we speak of an independent authority we have in view an authority not bent on simply putting owners to an unreasonable expense to the benefit of certain faddists and makers of certain kinds of appliances, but one who, once having decided which are the best, will act accordingly.

3. Sometimes asked to make a survey, but do not consider the agent's position between landlord and tenant a satisfactory one, unless acting independently.

4. Certainly yes. We cannot see why persons should be allowed to let insanitary tenements any more than a tradesman is allowed to sell food unfit for consumption.

5. This is a question of great importance, and one which cannot be too carefully looked into. All such places should be compelled to exhibit in a prominent position a properly authenticated certificate as to the sanitary condition.

6. We feel sure that the ordinary sanitary inspection can be much improved. Too much is left to the fads of the inspector instead of a proper scheme of sanitary laws fixed by a competent authority. We should say this authority has yet to be formed.

*Messrs. Ball, Norris and Hadley, London.*

1. No.

2. None beyond "drains all right."

3. Would be prepared to obtain, but not to make, a survey, as this should always be done by a specially qualified person, and one who has no other interest in the transaction.

4. No. The excuse for the provision in the case of working-class dwellings is that the tenants are unable to protect themselves; but the supposed benefit is a very doubtful one, and

redress can only be obtained by an expensive process of law after the mischief has been done.

5. The opinions given would apply to all classes of property.

6. We are of opinion that the true solution of the question is to be found in a system of sanitary registration as advocated by the Sanitary Assurance Association and provided for in the Sanitary Registration of Buildings Bill introduced by Dr. Farquharson, M.P., and the other medical members of the late House.

*Mr. Thomas Chaponau Barralet, Surveyor, Richmond.*

1. The average client is usually profoundly ignorant of the sanitary history and condition of the house he wishes to let or sell, unless he happens to be the builder of it or lives in it himself. As a rule the particulars we get are decidedly meagre. If sanitation be mentioned at all—and in five cases out of six it is not—it is in such general terms as “gravel soil,” “good drainage,” “drained into main sewer,” or more frequently the sweeping assertion “drainage perfect,” on the assurance of the builder from whom the house was purchased. I think more information on such points is desirable. That we do not get it is due to three causes: (1) Ignorance of client; (2) natural antipathy of owners to acknowledge defects; (3) neglect of agents to ask for information on such points.

2. Views coincide in the main with our scheme of drainage sketched above.

3. Yes; but considers that the surveyor should not be the house agent at the same time.

4. Personally favours the extension of the Act, but foresees it would bring a plentiful crop of litigation.

5. Legislation should fix responsibility on the owner and not on lodging-house keeper.

6. Local authority should keep a register, with plan of drains and special information relating to survey. Building by-laws should be compulsorily adopted throughout the country.

*Messrs. Thomas Bate and Co., Kilburn.*

1. Information insufficient.

2. From ignorance; property generally described as being in good sanitary condition when the converse is the case.

3. Yes; we are prepared to make an efficient survey.

4. Consider that in every case the owner of a house should be responsible for sanitary condition when the tenant enters into occupation, and that the local authority should be paid by the owner for efficient survey and certificate.

5. Remarks apply completely. This class of property should be certificated.

6. A survey should be made before tenant takes possession and at the cost of the owner.

*Mr. Frederic H. Boulton, Liverpool.*

1. In Liverpool and the out-townships the by-laws are very strict as to the responsibility of landlords to keep dwelling houses in sanitary repair. Tenants appear unwilling to pay the fees necessary for an expert's examination. It should be incumbent upon every health committee or local board, at the request in writing of a tenant or proposed tenant, to inspect and report upon the sanitary state of any property within their jurisdiction, and this report should be registered and a copy sent to the applicant and to the owner. If necessary a small fee might be charged on receipt of application, and the report be available for reference at any time on payment of the same.

3. Yes, but think reference to local authority a better plan.

4. Yes; “reasonably fit” should be clearly defined.

5. These houses should be examined by the local authority.

*Messrs. John and A. Bray, Hastings and St. Leonards-on-Sea.*

1. Not in the case of properties built before the application of the present by-laws and building clauses in the Hastings Improvement Act, except where from choice or necessity sanitary arrangements have been remodelled.

2. Our proposed sanitary certificate from the Town Council would, we submit, lead to all requisite matters being in proper order, to the satisfaction of house or apartment seekers.

3. It is generally a condition of hiring that houses shall pass such survey.

4. Yes, provided that in the case of lodging and boarding houses now held under leases varying in period the outlay does not fall on the tenant in making sanitary alterations.

5. Our opinions apply equally here.

*Mr. S. S. Bromhead, London.*

1. No.

2. (a) General statements like “drainage good”; (b),

periodical certificate from official inspector, which should be given free of cost.

3. No; because it would involve agent in trouble, and he would, besides, have difficulty in recovering his fee. It ought to be done by a public official, who would be responsible.

4. Yes, subject to official inspection.

5. These should be inspected annually.

*Mr. Samuel B. Clark and Son, London.*

1. Information insufficient.

2. (a) Unless a certificate is produced of recent sanitary improvements drains are pronounced to be sound; (b) in the case of furnished houses, a plan and certificate should be produced, but in unfurnished houses it may be assumed the tenant would have an inspection made.

3. We could not undertake the responsibility; and, as we should be acting on behalf of the owner, it is questionable whether the tenant would accept our survey.

4. No.

5. Furnished houses and lodging houses should have their sanitary arrangements periodically examined and certificated.

6. We would suggest that the various vestries should appoint a certain number of qualified surveyors in each district, whose services would be available to the public without fees. Many people object to the advertised societies or companies, under the impression that they are interested in pushing some particular system or fittings.

*Mr. John Douglas, London.*

1. In very few cases.

2. (a) The sort of information received is that no illness having occurred it is presumed the drains are all right; (b) plan of the main drain, with name of the surveyor who passed it.

3. I always make it a rule that all offers are subject to a sanitary report.

4. Yes, but it can be foreseen that the general application of the Act would lead to a good deal of litigation.

5. Every house let out for short periods or as lodgings should be under the supervision of the medical officer of health or district surveyor, and his certificate should be hung in the hall or passage. No lodging at seaside resorts should be countenanced without this certificate.

*Messrs. Driver and Co., London.*

We only let as a rule the vacant houses on the large estates for which we are agents and receivers. In these cases we inspect the sanitary arrangements on behalf of the owners, and, if found to be defective, they are put in order at the expense of the owner, the lessees and occupiers keeping them in order. When the estate comprises houses only, occupied on three years or yearly tenancies, the landlord first puts the estate in sanitary order and also keeps it in order at his own expense. When we undertake the letting of one or more houses for special clients for whom we are not agents or receivers, we make it our business to find out whether the sanitary arrangements are right, and where found to be out of order we advise the owner to have them put right before letting. In letting houses we never guarantee the sanitary arrangements, but inform the applicant that as far as we are aware they are fit and proper, and that it rests with the intending occupier to test the drains before taking the premises, and, if not satisfactory, the matter is thoroughly discussed between us and special arrangements come to in respect thereof. Before going into possession of a house a tenant should satisfy himself upon the question of the sanitary arrangements; but we find as a rule they object to pay a fee to an expert, and, that being so, they must put up with the consequences. Our experience of experts is this:—That there are many systems of drainage; and each expert naturally thinking his own scheme the best, some “defect” in the system of others is generally found. Thus, if any intending lessee wanted a certificate from us on behalf of the owner that the sanitary arrangements were fit and proper, we should decline to give it by reason of the difference of opinion which might exist between various experts if found necessary to call one in to decide the question of the soundness or otherwise of the sanitary arrangements.

*Messrs. Ellis, Morris and Co., London.*

1. As regards unfurnished houses of a rental of over £80 a year no change in the present custom is requisite. The public, however, should take the precaution of having the system of drainage inspected by a competent architect before signing any contract.

2. For a smaller class of house we should think legislation might be necessary, but as this does not come within the scope of our practice we leave it to others to suggest what is requisite.

3. For furnished houses, both in London and country, we are very strongly of opinion that some legal enactment is desirable. We would suggest that before letting apartments or furnished houses it should be compulsory for the owner to take out an annual licence, such licence to be only granted after the drainage has been inspected by some properly appointed official.

4. In taking permanent residences, we find that people are well able to look after themselves, but in securing temporary abodes, and perhaps more especially at the seaside, they are in too great a hurry to take more than a superficial inspection, and no doubt more illnesses are contracted this way than any other.

*Messrs. F. S. Jennings and Co., London.*

1. Information insufficient. If there be anything specially advantageous in regard to the sanitary arrangements it is generally very strongly impressed upon us and very often in terms which the result does not justify. In ordinary cases this is not referred to, or if mentioned it is only in very general terms, from which the agent has to draw his conclusions for the benefit of his client.

2. Our opinion is that it should be absolutely necessary for a landlord to obtain a certificate from some public official to be appointed for the purpose.

3. If any doubt arise, we suggest that a survey should be made by an independent person at the expense of the tenant. Not in one case in fifty would the owner offer to pay the expense.

4. Certainly.

5. It is, in our opinion, desirable that the Act referred to in the foregoing question (No. 4) should be also applied to such lettings as these.

6. The desired reform can only be brought about by legislation. Agreements between firms of leading house agents would be difficult to bring about; and if concluded would not be binding on anyone except themselves; with the result that if the combined firms who declined to deal with a house in which the sanitation was unsatisfactory, the owner would employ an agent outside the combination, with the result that his unscrupulous conduct in dealing with it would perpetuate evils.

*Mr. W. A. Hall, London.*

1. Information insufficient.

2. The tenant should obtain the necessary information at his own expense.

3. Yes.

4. No. Would lead to endless litigation.

5. Not able to express an opinion.

6. The present state of affairs can be better remedied by more effective administration of existing Acts than by recourse to further legislation.

*Messrs. Horncastle and Pember, London.*

1. No. Usually our first question; and the replies returned are generally vague.

2. That the house has been drained in accordance with the modern system, which our surveyor could verify.

3. Yes. A sanitary surveyor is a member of our staff.

4. No dwelling should be let that is not reasonably fit for human habitation; but nothing should be taken for granted, and the tenant should be satisfied by an independent survey.

5. We should like the above rule to be applied here; but we fear the in-going tenant would shirk the expense in the case of a short let.

6. No hard-and-fast legislation will be entirely satisfactory and every case of letting should stand on its own merits. We wish to point out that a great many so-called surveyors have had little or no practical experience.

*A Firm of Estate Agents at Bournemouth.*

The necessary reform can be best accomplished by legislation. Where not in force, Local Improvement Acts should be adopted, compelling owners of buildings erected before the passing of the Act to bring the drainage of their houses into conformity with the requirements of the Act. When the necessary alterations have been carried out, application should be made to the local authority to inspect the drainage. If found satisfactory a certificate to that effect should be granted. A fee should be paid for certification.

*Messrs. Fred. Long and Sons, London.*

1. No.

2. (a) Either no information or information in such general terms as makes it necessary for the proposed tenant to satisfy himself as to the sanitary condition of the premises; (b) in our opinion the only information that would be of any real value would be the certificate of some competent authority as to the sanitary condition of the premises.

3. We are not prepared to make a survey of the sanitary arrangements of property placed in our hands for letting, but we are prepared to obtain an efficient and independent sanitary survey of such property—indeed, we recommend it. We are of opinion that our position as agents interested in the letting of the property is better kept free from responsibilities for the sanitary condition of the same.

4. We do not think it would be wise to make Section 12 of the Housing of the Working Classes Act apply to dwellings. The provision in question is much too general, and might lead to great injustice. What is wanted is definite information as to the sanitary condition of each and every house occupied; not an implication which is inoperative until a serious disaster results, followed by a long and expensive legal process to recover damages. The first step towards securing the desired information would appear to be the sanitary registration of buildings as certified by duly qualified sanitary licentiates in manner provided for in the Sanitary Registration of Buildings Bill, introduced into the last Parliament by Dr. R. Farquharson, M.P.

5. Our opinion as given above would apply to all buildings alike, except that with regard to hotels and houses let in lodgings. We think the proposed changes in the law should be made operative at once, while with other property let for any long term the proposed change might be made in a more gradual manner.

6. We are of opinion that it would—at all events at present—be a mistake to attempt to throw upon the community the responsibility for the sanitary condition of private property, as would be the case if the sanitary arrangements of all houses came under the care of public officials. We, nevertheless, hold that it should be the duty of the State in the interests of the community to insist on proper attention being given by the owners to the sanitary condition of all occupied buildings.

*Mr. John Marsden, ex-Chairman of the Health Committee, Corporation of Blackpool.*

1. No information is ever given by the owners of property about sanitation.

2. No house should be let by a landlord or agent unless he produces a certificate from the medical officer of health that a recent inspection has been made of the premises.

3. Yes, if desired by the incoming tenant and with the permission of the landlord. In this town any tenant can have his house inspected on application to the medical officer of health.

4. Most certainly.

5. I consider that seaside houses ought to be put under the most rigid control as regards sanitation, and that such control ought to be in the hands of the State, and not in the hands of local authorities.

6. In many seaside places certificates are granted by the local authority; but these are most misleading, as I have known them to be.

*Messrs. Lovtan and Sons, London.*

We consider that generally speaking the public can only be effectually protected against insanitary houses by legislation, and not by agreement between the leading firms of house agents. Some owners do not disclose the insanitary condition of their houses when instructing agents to dispose of them, but the public are now so alive to the necessity of proper drainage that an inquiry as to the condition of the house in that respect is one of the first made by an intending tenant. We would never allow a client who consulted us to purchase or lease a house without first having a proper survey made of the sanitary arrangements, but while such an expense can easily be borne by wealthy people it presses very hard on those who are in search of small houses. We feel very strongly that it should be incumbent on all owners of house property to put the drainage into proper condition, and we therefore give a very emphatic "Yes" in reply to your fourth suggestion. Inasmuch as those seeking houses or lodgings at

seaside places and health resorts have so little time to make the necessary survey our opinions expressed above would apply with greater force if possible to houses of that description. In some seaside places we think the local sanitary authorities have by-laws giving effect to what we so much desire.

Legislation on such a subject is doubtless fraught with many difficulties, but they should be overcome when the health of the public is at stake.

*Mr. Samuel Reynolds, Bognor.*

1. Yes. So far as Bognor is concerned, there has been a house to house inspection by the local authorities during the last few years, and all defective drainage has been compelled to be put right. Any person taking a house can go to the local authority and obtain accurate information as to what has been done under order of the surveyor to any house in the district.

2. I should apply to the medical officer of health as to the past history of the house.

3. Yes.

4. Yes; but I fear in some cases the official authorities are apt to overstrain the necessity, causing landlords unnecessary expense, and serving notice to put the house in sanitary condition, and refusing to supply any detailed information of what they require. This is a weak point in the Act, and leads to much arbitrary proceeding.

5. As a rule persons letting lodgings or houses where there are proper local authorities will for their own sakes have them in good order.

6. Unprincipled people not uncommonly try to get out of an agreement by making false statements about the drainage. More than half the complaints are much beyond the truth.

*A Firm of Surveyors in London.*

1. Information insufficient, through ignorance and not from wilful suppression of facts within the knowledge of the landlord.

2. The tenant should satisfy himself regarding the sanitary condition of his house, and himself do what is necessary to put it into thorough order.

3. Yes.

4. It would be most undesirable to extend this provision to all houses.

5. A furnished house should always be let in a condition fit for habitation, because a person taking a house for a short period cannot reasonably be expected to deal with the drains.

*Mr. J. Stopher, London.*

1. No. It frequently happens that owners have no knowledge either of the condition or plans of the drainage.

2. (a) General statement that the drains are in good order; (b) plan of the drains with necessary description.

3. Yes; but of course this is a matter for an intending tenant. Always advise a thorough sanitary inspection before taking a property.

4. Yes; an owner of property should take every reasonable precaution to ascertain that his house is fit for human habitation.

5. From observation I believe that, except in houses erected during the past ten years, there are more death traps at the seaside and health resorts than in some of the worst parts of London. I consider that there is need for most stringent examination before taking a house at the seaside.

6. For the protection of house agents it would be advisable to agree that a house should not be recommended unless when information is given that a certificate from a competent surveyor of the efficiency of the sanitary condition has been shown. Every water company should be compelled to give continuous water supply. This evil of insufficient water supply is the cause of frequent stoppage of drains.

*Mr. T. G. Wharton, London.*

1. No.

2. Usual to state whether the house has been drained into the main sewer or cesspool, and if the premises have recently been put in order. I think there is considerable risk to the owner in making statements which might be construed into a guarantee.

3. Yes.

4. No, I consider it would be unfair. An owner as a rule conscientiously believes his drains are in good order, and probably as a matter of fact they were so when the house was built; or even if they were not his architect or builder certified that they were. Why should an innocent owner,

having no knowledge of the case, be made subject to actions for damages? Of course if he knowingly let a house in an insanitary condition it is a different matter. Having regard to the powers of the local authority and to the facility for inspection always given to an intending tenant, I consider he should look out for himself.

5. Furnished house or apartments should imply good drainage also.

6. I suggest it would be useful if an owner were compelled every seven years to have the drains and fittings tested by the local authority, or at his option by a properly qualified surveyor. In the case of a property let for longer than seven years this duty should devolve on the lessee.

*Mr. E. H. Winkworth, Brighton.*

1. In an ordinary case where the letting of an unfurnished house is concerned the intending tenant invariably stipulates for the drainage to be approved by his surveyor and any necessary work done. In furnished houses I am supplied with all available information. It would be advisable to have a proper certificate from a thoroughly qualified surveyor.

2. The sort of information which would be valuable could be furnished by a plan of the sanitary arrangements, water-supply and fittings, together with a proper certificate of efficiency from time to time. Many of my clients have an annual inspection, including a test of the drains by water-pressure. I consider this a good arrangement.

3. Yes, certainly.

4. This is an implied covenant with furnished houses.

5. I consider that if the drainage or water-supply is defective in any way it should be remedied irrespective of whether the house is for letting as a whole or in part, or for long or short periods.

6. The course which appears to work best is to offer every facility to tenants or purchasers to have a thorough inspection and test made by their own surveyor. All houses building in Brighton have to expose the drain, and test with water to the satisfaction of the town authorities. Even in a properly drained and fitted house trouble will occur unless servants are carefully instructed, and I think it essential to have printed directions.

*Messrs. John D. Wood and Co., London.*

1. Owners find it advantageous to themselves to put forward sanitary conditions when of approved plan and construction as one of the attractions of their places. Buyers and tenants are increasingly particular as to sanitary conditions, and make their offer subject to a sanitary survey, carried out by a surveyor at their own expense.

2. (a) In our printed form we ask the questions, Are the sanitary arrangements on the modern principle, and who planned and superintended the works? (b) Has the house been drained on modern principles?

3. We advise buyers or tenants to supplement by a detailed survey.

4. Should be extended to property having a rental of £40 per annum, but not further. For better class property sanitary condition should be a matter of mutual agreement.

5. Fully. All hotels and houses where lodgings are let should come under Section 12 of the Housing of the Working Classes Act.

6. For the last fifteen or eighteen years great stress has been laid on sanitary conditions, and in the West-end it is almost impossible to let a furnished house unless the sanitary arrangements have been reconstructed. This also applies to country houses, but to a less extent. Speculators in house property recognise this fact, and take care that the sanitary arrangements of a house are in good order. We think that a recognition of a minimum of sanitary requirements (legal or otherwise) would be helpful in inducing owners to bring their houses up to the required standard, leaving for private agreement the elaboration of details, such as irrigation, grease traps &c.—antisiphonage, disconnecting and inspection chambers.

It should be imperative that all who execute sanitary works or superintend their execution should give a certificate showing works executed and manner of execution, illustrated by a plan, this certificate and plan to be producible on demand.

#### SUMMARY.

From the amount of information which we have placed before our readers two facts must have become apparent to them. (1) That there is a vast amount of ignorance abroad, both amongst landlords and tenants, as to what sanitary

conditions should be fulfilled before a house may be considered habitable; (2) that sanitary defects are largely prevalent in houses in all parts of the country, especially in those erected before the adoption of the Local Improvement Acts or Model By-laws, and that some reform is necessary in the law and practice of house-letting for the better protection of tenants, and, we think, in the end for the advantage of landlords also. To attain this desirable result, however, some plan must be evolved, which, while affording effectual protection to the tenant, will not inflict a positive injustice on the landlord. Some of our correspondents have urged that the matter is entirely in the hands of the tenant, and that as it is the duty of every man to look after himself no further legislation is desirable. It is contended by them that all a proposing tenant has to do is to call in his own surveyor and be satisfied by an expert opinion that the drainage is in good order. One gentleman, insisting strongly on this plan, compares the taking of a house to the purchase of a piano, in which he says a man takes the precaution to satisfy himself that he is getting his money's worth, and he asks why he should not apply the same laudable rule in the matter of his house. It appears to us, however, that whereas in the former case a man may get his opinion gratis, in the case of a house he must pay in order to find out whether the article offered is genuine. We must confess that we cannot see why a landlord who spares no trouble to put the rest of his house in order should systematically overlook the condition of the drains, or pass them over with the statement that they are "all right" or "have given no trouble." Nor are we able to appreciate the logic of the rule which says that the tenant must pay for the privilege of pointing out to the landlord that he is letting a house with the drains out of repair.

Granting, then, that reform is necessary, it appears to us that the desired improvement might be obtained in one of three ways: (1) By a combination of house agents and surveyors; (2) by further legislation; (3) by awakening sanitary authorities to a sense of the power already entrusted to them, and requiring them to develop their latent authority for the public benefit.

Regarding the first suggestion it has been pointed out that agreement between the leading firms of house agents would be difficult to accomplish, and when effected would not be binding on anyone except themselves. Moreover, the owner would always have it in his power, supposing the verdict were against him, to appeal to some firm outside the union. With this opinion we entirely agree.

In the event of the desired end being attained by further legislation we presume that some such Act as the Sanitary Registration of Buildings Bill, introduced by Dr. Farquharson into the late Parliament, would be requisite. Probably before a house could be put on a "sanitary register," the landlord would be compelled to place the drainage of his house in conformity with the requirements of the Bill. This would effect the improvement by a sweeping and revolutionary change, and, while meeting with disfavour amongst landlords, would probably entail no little trouble on the sanitary authorities. We would suggest that some more gradual innovation should first be attempted.

We are now left only with the law as it stands, and we are driven to ask whether, in spite of the evils which appear to flourish under it, it does not hold out any hope of assistance by more efficient administration and a more complete use of its powers. We venture to think that it does; and in the course of this report we have already instanced cases where it has done so. Under the Metropolis Local Management Act, 1855, Section 202, the London County Council is empowered to make by-laws "for regulating the dimensions, form and mode of construction, and the keeping, cleansing and repairing of pipes, drains and other means of communicating with sewers, and the traps and apparatus connected therewith." Other sections of this Act empower the vestries and district boards to require houses to be drained, and by Section 82 the sanitary authority is granted power to inspect at any reasonable time during the day any drain after twenty-four hours' notice in writing had been given to the occupier of the premises. By Section 39 of the Public Health (London) Act the County Council is required to make by-laws with respect to waterclosets, earth-closets, privies, ashpits, cesspools—whether constructed before or after the passing of the Act, and the sanitary authority to make by-laws with respect to the keeping of waterclosets supplied with sufficient water for their effective action. Every sanitary authority is moreover required to observe and carry out the by-laws under this

section. By Section 40 of the same Act the sanitary authority is given the same power of entry and of inspection of waterclosets, sinks, traps &c. as was conferred by Section 82 of the Metropolis Management Act in respect of drains, and they can enforce whatever alterations appear necessary. By the Public Health Act, 1875, Section 157, every urban authority was empowered to make by-laws "with respect to the drainage of buildings, to waterclosets, earth-closets, privies, ashpits and cesspools in connexion with buildings, and to the closing of buildings or parts of buildings unfit for human habitation" &c. Again, the Public Health Acts Amendment Act of 1890 enables these by-laws to be made to affect buildings erected before the Local Government Acts came into force in the district. We see, then, that in the matter of sanitation the law makes the local authority practically supreme if it cares to exercise its rights, for it is not only permitted entry at any reasonable time during the day if dissatisfied with the sanitary condition of any house, but it may frame by-laws and enforce them with respect to sanitary appliances.

Now the plan which appeals to us most strongly, and one which appears most likely to secure the desired end most easily and smoothly, is that which has already been put in action with successful result at Eastbourne. By this method the local authority offers to grant certificates to landlords if their houses come up to their standard of sanitary excellence, and houses so certificated are put upon the register of the local authority. The sanitary authority has acted most wisely by making the registration a voluntary one, for by so doing they have converted what might have been looked upon as a grievous hardship into a mark of distinction. As was to be anticipated, landlords have not been slow to avail themselves of the privilege, for it necessarily affords them a better chance of letting their houses; and we have little doubt that in time the majority of houses will have been put on the register.

Having agreed that it is desirable that the local authority shall institute a plan of registration of houses after the granting of their certificate, we have next to consider how this certificate shall be gained. The various means of certification that we have come across in this inquiry are: (1) By the builder; (2) by the surveyor; (3) by sanitary associations; (4) by the local authority, who shall be the sole surveyors. We scarcely think it advisable that the local authority should accept certificates from builders, surveyors or sanitary associations as qualifications for registration; for however honourable are the majority of men engaged in these professions, such a plan has of course very evident shortcomings. Much as we should disapprove of this suggestion being carried into effect, we still more dissent from the one which constitutes the local authority the sole surveyor; if by surveying be meant the planning and laying down of drains, for this would evidently strike at the root of private enterprise, and would be an intolerable injustice. We should rather suggest that every sanitary authority should issue a code of by-laws setting forth its standard of sanitary excellence. The work should be carried out by private agency, but when finished should be passed by the surveyor or sanitary inspector of the local authority; and if the report be satisfactory a certificate to that effect should be granted and signed by the person who inspected the house. It would also be advisable on obtaining the certificate that a plan of the drainage should be deposited with the local authority, which should be open to inspection at some future time on payment of a small fee.

While we would advocate the system of voluntary registration for private houses, we think that in the case of hotels, lodging and boarding houses registration should be compulsory. Our remarks would apply with especial force to seaside places and health resorts, whither people go in search of health, and find perchance, instead, a sick bed or something worse. In houses of this class the public have not the opportunity, however capable they may be, of satisfying themselves about sanitary conditions, and it is therefore only fair that they should be protected to the fullest extent. Once having gained a certificate from the local authority, how long shall it be considered to hold good? We would suggest that in the case of hotels, lodging and boarding houses the renewal should be annual, the fresh certificate being granted provided no nuisance has arisen in the interim. Private houses, we think, might be certified at each change of tenancy, notice being sent to the local authority when this occurs, or, in the case of long tenancies, at intervals of not more than seven years' duration.

A TABLE SHOWING THE OPINIONS OF 136 HOUSE AGENTS UPON THE SEVERAL QUESTIONS SUBMITTED TO THEM FOR THE PURPOSES OF THE LANCET INQUIRY.

Questions.	Yes. No.	No answer.	No. asked or given.	Vague information.	No answer.	Certification.	No answer.	Plans and certificates.	History of houses.	Sanitary tests.	Improvement Acts.	Yes.	No.	Yes, No.	No answer.	Apply equally.	Do not apply.	No answer.	Make suggestions.	No suggestions.

VI.—If any points occur to you in this connexion which are not already covered please mention them here. ... ..	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	107	3	26	—	80
	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	—	56

A landlord having satisfied his tenant by the production of the certificate of the local authority, that the drainage of his house is in thorough order, we hold that he should be exonerated from all responsibility in the event of mischief occurring during the tenancy. On the other hand, should the tenant wilfully cause a stoppage of a drain the landlord is protected by Section 15 of the Public Health (London) Act, which imposes on the tenant a penalty of £5; while for damage to sanitary appliances he is by Section 41 of the same Act liable to a fine of £10; and if he does not abate the nuisance within fourteen days to a fine of twenty shillings for each day during which the offence continues. It has been suggested that schools, public and private, should be inspected and reported on as regards their sanitary condition. This is an important suggestion, and one which we should be glad to see carried into effect.

Through the kindness of several house agents we have had forwarded to us copies of the printed form of agreement usually employed by them in the letting of furnished houses, and we have been much impressed with the fact that none of them contains any direct allusion to the subject of drainage, although space is left in some in which the tenant may make conditions regarding sanitation. We would submit that stipulations regarding the drainage should enter into every agreement in the letting of a furnished house, and would suggest the following as a model form:—

Memorandum of an agreement made and entered into this.....day of.....one thousand eight hundred and....., by and between..... of....., auctioneer and valuer, house and estate agent, acting as agent for..... of the one part and..... of....., heirs, executors, administrators or assigns of the other part as follows—that is to say, the said..... hereby agrees to let, and the said..... hereby agrees to take all that messuage or dwelling-house and premises, situate and known as....., together with the furniture, glass, china and effects now therein, as per inventory, from the..... for the period of....., the landlord guaranteeing that the sanitary arrangements of the said messuage, dwelling-house, and premises are in thorough order.....; and the said..... further agrees to pay the said rent..... (Here follow the usual stipulations regarding rent and right of re-entry of the agent in case of default of payment.)

The Editors of THE LANCET have pleasure in acknowledging the receipt of replies to their circular from the following firms of house agents and surveyors, and thank them for the kind assistance they have afforded them during the work of the Commission:—

Mr. J. Adam, Dublin.  
Messrs. Alder and Co., London.  
Messrs. Baker and Son, Hastings.  
Messrs. Ball, Norris and Hadley, London.  
Mr. H. Barnwell, Birmingham.

## ANNUAL REPORT OF THE SANITARY COMMISSIONER WITH THE GOVERNMENT OF INDIA FOR 1890.<sup>1</sup>

THESE voluminous reports which are annually drawn up in the office of the Sanitary Commissioner with the Government of India embody a vast amount of information. They deal with the sickness and mortality among the European troops, native army, prisoners, and general population of India, and the tables and returns are so compiled and arranged and ingeniously thrown into such groups and forms as to afford information to a statesman, Government official, or medical officer on a variety of subjects about which it is sometimes very essential for him to know a good deal. Information regarding the birth, death and sick rates of the enormous native populations of India—over 280 millions of people—is confessedly unreliable. Our systems of registration are at present so imperfectly carried out there that it cannot be otherwise. But the statistical data obtained from the British and native troops and the gaol population are trustworthy and serve as a gauge and check on the returns furnished from native sources. The late Dr. Bryden may, we believe, be credited with having created the statistical department and with having in a great measure designed the valuable tabular statements that have been continued in these reports since his time. If the reader turns to that portion of the report and appendix appropriated to the European troops in India, he will see—to take a few samples of the kind of information afforded—that the geography and topography of diseases, the influence of season, the comparative ratios of sickness and mortality of the armies of the three presidencies and of the different districts and chief military stations in them, the vital statistics of hill stations, the relation of disease, and of certain diseases in particular, to age and length of service, the gain and loss of strength of corps, and the vital statistics of the women and children of European regiments, are all set forth. To proceed, however, to the report itself. After the usual summary of the meteorological phenomena for the

<sup>1</sup> Government Printing Office, Calcutta, 1892.

year 1890 we come to the section on the European army in India as a whole. The sickness was greater than in the previous year, though the mortality was much less. But for the epidemic of influenza the year would have been a fairly healthy one. Influenza caused an admission rate of 33 per 1000, pneumonia one of 4.6, against 2.6 in the previous year, and other respiratory diseases 35, against 29 per 1000 of the previous year. Venereal diseases caused 33 per cent. of the total sickness, and ague 23 per cent. In all three presidencies venereal diseases head the list, show higher ratios than in the previous year, and much higher than in the decennium. Enteric fever caused 36 per cent. of the total deaths, against 37 per cent. in the preceding year. Of the three presidencies Bombay shows the lowest ratio of sickness and of deaths, Bengal the highest in both these respects.

In 1890 India shared in the pandemic of influenza, which first showed itself epidemically in Russia in September-October, 1889, and thence spread over Europe, reaching its height there in December. The facts set forth in the report are interesting, and we may therefore briefly advert to them. The first cases in Egypt were noticed in the last half of December. In India a few cases are returned as influenza every year, and in 1889 the cases so returned amounted to 5 among European troops, 7 among native troops and 33 among prisoners, the last representing a curious isolated outbreak in August, 1889, among the prisoners of the 'Thayetnyo gaol; and not only were the prisoners affected by it, but members of the gaol guard and gaol establishment also. In Bombay and Calcutta cases were first noticed in February, 1890, in Rangoon and probably Madras in the middle of March; but the Sanitary Commissioner, North-Western Provinces and Oudh, states that influenza was epidemic in the Jalaun district from the middle of January and in the Bijnor district from February. The area covered by the disease was very large, extending, in fact, over nearly the whole of India. It affected European and native troops and prisoners and the natives themselves, only the statistical evidence in regard to the latter is necessarily meagre and unreliable. Its general prevalence was confined within very narrow limits of time, commencing with few exceptions in March, attaining its maximum in April and then disappearing. It seems to have been less prevalent among the women and children than among the men of European regiments. There was, of course, a great increase of pneumonia and pulmonary disease concurrent with or immediately following the epidemic. The disease was attributed to importation by many observers. The number of admissions to hospital affords no idea of the numbers affected by it. At one station the medical officer estimated that as many as 30 per cent. of the garrison was affected; at another the estimate of the medical officer was even 80 per cent. Although the general mortality of the European army was not raised by influenza directly, the death-rate from pneumonia and respiratory disease was markedly increased and no doubt attributable to it as a cause. In some cases it is noted that the Europeans suffered much less severely than the natives in the same station. It is of interest to learn, on the authority of the principal veterinary officer in India, that there was no preceding or concurrent epidemic, like or unlike influenza, among horses.

Passing over other diseases, we turn to the grave and important subject of enteric fever. The remarkable liability of the young and newly arrived soldier in India to this fever—and especially of the soldier recently arrived there—is an acknowledged fact which has been thoroughly threshed out. But the true cause has still to be sought. It cannot be imperfect drains and sewer air, because there are no sewers in India to befoul the air or leak into the water-supply, and it has never yet been actually demonstrated that the natives of India commonly suffer from the disease—at any rate, to anything like the extent that Europeans do—and distribute its germs broadcast over the bazaars and native villages. Still, the opinion among medical officers in India is that the enteric fever of that country, however masked its clinical features may sometimes be by climatic conditions, is essentially the same in pathology as the corresponding fever in Europe. In this opinion they are no doubt right, and it seems only logical to suppose that the self-same cause which produces the disease in the one country must be operative in the other also if we could only find it out and, having discovered it, track it home to its haunts and show what it is, how it originates, in what and under what conditions it grows and develops, and how it gains an introduction into the human body.

Our thoughts naturally turn to the latest discovered typhoid bacillus. If this proves to be the *vera causa*, or the agent through whose instrumentality a process is set up in the tissues productive of a poison or ptomaine, then we may possibly have found a pathway leading to an assured basis of scientific fact to which we can relegate the etiology of typhoid fever and learn the why and the wherefore of the disease and the best way of preventing it.

Since the last report specimens of three more cases occurring among European soldiers in Lucknow and Fyzabad were submitted, we are told, to Professor Fischer of Kiel, in one of which he had found the bacillus, but had not yet reported as to the others. Specimens of spleen and mesenteric glands from the case of a native soldier who died of a fever diagnosed as enteric were also forwarded, but Professor Fischer failed to demonstrate the presence of the bacillus in a number of sections he had made. The truth of the assertion that the same enteric fever occurs among natives as among Europeans has therefore yet to be demonstrated in this direction. On the other hand, Dr. Justyn Karlinski has published two cases in which the symptoms were anomalous and no intestinal lesions were present, and yet a bacillus was found by cultivation from the spleen and other internal organs; and another in which with only an old cicatrix in the intestine the bacilli were recovered from the blood by cultivation. This observation opens up a wide field of inquiry, and we quite agree with the Sanitary Commissioner with the Government of India that, if confirmed, it will still more emphasise the need of bacteriological examination of Indian cases. These investigations, it is pointed out, can only be carried out in properly equipped institutions by trained observers with the necessary combination of leisure and apparatus. It is time that the sea-saw of asseveration and the promulgation of hypotheses should be replaced by results obtained by some exact and systematically pursued methods of inquiry. We have all along contended that something of this kind should be done, and, what is more, we consider that it would be well at the same time to set about some practical sanitary inquiry and to organise some sort of public health department in India, with local head centres at the several districts or larger military stations, to undertake and report upon any outbreaks of this disease at the time of their occurrence. We should also like to hear that samples of water taken indiscriminately from barrack-room filters had been chemically analysed and submitted to bacteriological tests. A primary question that requires to be practically decided is as to the prevalence or not of enteric fever among the native population. Is it among them a disease of infantile life or not? Our own personal experience is rather corroborative of the opinion of those who hold that true enteric fever is relatively rare among infants and young children in England. To what is the alleged immunity of the native as compared with Europeans from enteric fever attributable? To an acquired tolerance or what? The sanitary commissioner has himself suggested numerous subjects for inquiry, and it should not be difficult to formulate instructions for conducting such an investigation. We earnestly hope to see it done. In the following table the admission and death-rates per 1000 from enteric fever in the European troops, native troops, and gaols of India are compared:—

—	1877 to 1880.		1890.	
	Admissions.	Deaths.	Admissions.	Deaths.
European troops ..	8.0	3.15	13.6	4.01
Native troops .. ..	0.2	0.10	0.1	0.07
Gaol population ..	0.2	0.10	0.2	0.00

The percentage mortality of enteric fever in deaths from all causes in 1890 was 35.5 for European troops and 0.4 for native troops. Of one thing there can be no doubt in the meanwhile—viz., that the soldier recently arrived in India is far more apt to die from enteric fever than he who has been longer in the country, and that with increased service in India the liability to death from enteric fever rapidly diminishes. In 1890 the percentage of liability in the case of soldiers during their first and second years of service was 66.47, as compared with 14.13 of those from the sixth to the tenth year of service—a very striking difference.

Passing on to the section dealing with the general population of India, we find that cholera was widely distributed in the year 1890. No province was exempt from epidemic

cholera, and the only large area that entirely escaped was the north-west frontier of the Punjab: 'There were only a few cases in the eastern parts of the central provinces and the coast districts north of Madras. The total number of deaths recorded was 297,443, which is much less than in the previous year, viz., 428,923, though rather more than in 1888. The report contains a table of the annual deaths from cholera in India from 1887 to 1890, from which it will be seen what a terrible scourge this disease is in India. For the year 1890 the province of Bengal (excluding Calcutta) heads the list in the number of population and deaths from cholera; next the North-West Provinces and Oudh; and Madras stands third in mortality; Berar, Lower Burma and Coorg, where, in a population of over 178,000, there were only five deaths from cholera during the year, stand at the bottom of the list. With regard to the causes assigned by different observers for various outbreaks of this disease we may mention that unprotected water-supply and contaminated water, importation of the disease, its more rapid distribution by the agency of railways and pilgrims are among the more important alluded to. It is to be regretted that in several instances the evidence in favour of a given conclusion is not as precise and complete as could be desired, and the Sanitary Commissioner calls attention to the fact. In the history, for example, of a remarkable outbreak which occurred at a place called Bilaspur the date of the feast is not given. We are not told whether cholera was present in the sixteen villages before the return to these villages of persons who had been at the feast or whether it afterwards broke out among those who had never been there. Again, with regard to the details connected with the alleged more rapid distribution of the disease in the Punjab by railways, it is significantly pointed out that the almost simultaneous appearance of cholera in widely separated districts of a province is no new fact, and that this feature in the spread of the disease through the Punjab is certainly older than most if not all the railways. Cholera, moreover, was already present in Umballa and other districts through which the pilgrims had to pass. At page 148 of the report there is a table, in continuation of those given in past years, showing the percentage of attendants on cholera cases attacked by that disease—viz., 3.15, which seems high. We infer from the report, however, that the circumstances connected with these attacks were not such as to warrant the conclusion that they were attributable to such attendance. The curious instances of localisation of the disease on the one hand and the beneficial results attending the movement of human beings from an affected locality into camp on the other would rather seem to indicate the influence of place instead of persons in the matter.

In the short section headed "General Remarks," Surgeon-Major-General Rice, the Sanitary Commissioner, gives a summary of the events connected with the outbreak of cholera at the Haj in 1890 after an interval of six years' freedom from that disease; of those connected with the quarantine at Camaran; of the interesting circumstances connected with outbreak of cholera in the s.s. *Deccan*, the only vessel attacked of thirty ships during the pilgrim season; and of an outbreak on board the s.s. *Malacca* while on her way from Jeddah to Constantinople in August, 1890, at the close of the pilgrim season. The concluding paragraphs of this section deal with the scientific memoirs published in connexion with the report. Surgeon-Captain G. M. Giles has, it appears, added in a series of notes some collateral investigations connected with his inquiry into the nature of the disease known as kala-azar and its relation to the life-history of the *Dochmius duodenalis*. In some of these notes this medical officer has traced out a similar life-history of a closely allied equine parasite, which he believes, in conjunction with two other closely allied species, to have been the cause of a serious mortality among horses and mules at Shillong, and in others he has described a parasite which gives rise to disease of the intestine of sheep, together with a description of two newly observed ovine parasites. Lastly, allusion is made to Surgeon-Captain Charles' account of some specimens which illustrate the life-history and morphology of the Guinea worm. We have only touched on some salient points in our analysis of this report, which contains, as we have said, a vast amount of information ably and lucidly arranged and set forth.

DR. J. DAVIDSON (Uxbridge) has been awarded the Government grant for public vaccination for the first time.

## COLOUR-BLINDNESS.

IT was appropriate that Professor Rutherford, the President of the Biological Section of the last meeting of the British Association for the Advancement of Science, at Edinburgh, should select this subject for his address, since colour-blindness was first shown to be of high practical importance by Professor George Wilson of Edinburgh. The lecture was brilliantly illustrated by means both of diagrams and of demonstrations with the magic lantern, which materially added to its interest. After describing the sensory mechanism of sight, including the retina, optic nerve, and the centre for visual sensation, Professor Rutherford showed how the ether waves of a beam of white light can be dispersed by a prism or diffraction grating, and that those able to stimulate the retina are comprised within a range of rather less than one octave, extending from a frequency of about 395 billions per second at the extreme red end to about 757 billions at the extreme violet end of the visible spectrum. The ultra-violet waves in the spectrum of sunlight extend through rather more than half an octave. These, though mainly revealed by their chemical effects, are not altogether invisible, but have a bluish-grey colour. Colours, he pointed out, are commonly defined by three qualities or constants—hue, purity, and brightness. The hue depends on the chromatic effect of frequency of undulation or wave length; purity or saturation depends on freedom of admixture with sensations produced by other colours or by white light; and brightness or luminosity depends on the degree to which the sensory mechanism is stimulated. He admitted the great difficulty that is offered to any attempt at explaining the phenomena of colour-blindness. He adverted to the cases of apoplectic seizure in which partial or complete unilateral or bilateral loss of the colour sense had been observed, and showed how the symptoms supplied evidence: first, that a sense of light does not imply a sense of colour; and, secondly, that the colour sense involves a more highly refined action of the sensory cell than the mere sense of light and form, and is on that account more liable to be lost when the nutrition of the sensory cell is interfered with. Professor Rutherford described the usual method of ascertaining the existence of colour-blindness by means of coloured wools, and showed that the confusions of brown, orange, green, and grey with bright red; of pale red, orange, yellow, and grey with green; and of blue, violet, and green with pink, had all their explanation in the fact that the red-green blind have only two colour sensations, yellow or blue, with a grey or white band in what should be the green part of the spectrum. Another and more striking method of ascertaining what fundamental sensations are absent in the colour-blind—that method, in fact, which was long ago termed "simultaneous contrast" by Chevreul—consists in throwing a beam of coloured light on a white screen, whilst an opaque object is interposed in its path, when the shadow will be found to show the complementary colour. If the light be red, the shadow appears green-blue; if it be green, the shadow appears purple or red, according to the nature of the green light employed. If the light be yellow, the shadow is blue; if it be blue, the shadow is yellow. It must be remembered that the part of the screen on which the shadow falls is not entirely dark; a little diffuse light falls on the retina from the shadowed part, so that the retina and vision centre are slightly stimulated where the image of the shadow falls. The question constantly recurs, Does light stimulate the optic terminals by inducing vibration or by setting up chemical change? Now, from Lippmann's recent researches on the "Photography of Colour" it appears that all parts of the spectrum can be photographed on films of albuminobromide of silver, to which two aniline substances, azaline and cyanine, have been added. It seems, therefore, reasonable to suppose that a relatively small number of substances can enable all rays of the visible spectrum to affect the retina. Apparently the question becomes narrowed down to this: Do the nerve impulses arise from mere vibration or from chemical change in the molecules of the nerve terminals? The photo-chemical hypothesis has much in its favour. We know how rapidly light can induce chemical change in photographic films, and we know that light induces chemical change in the vision purple in the outer segments of the rod cells of the retina. The fatigue of the retina produced by

bright light is best explained on a chemical theory, but it could also be explained, Professor Rutherford thinks, on a mechanical theory; for even if the nerve impulses produced in the visual cells be merely a translation of the energy of light into vibration of nerve molecules, the nerve impulse has to pass through layers of ganglionic cells before reaching the fibres of the optic nerve, and in these cells it probably always induces chemical change. In concluding what Professor Burdon Sanderson afterwards eulogised as a lecture of the highest interest, Professor Rutherford eloquently observed that in the progress of scientific thought it is especially necessary to keep our minds free from the thralldom of established theory. Theories are but the leaves of the tree of science; they bud and expand, and in time they fade and fall, but they enable the tree to breathe and live.

## THE CIVIL MEDICAL DEPARTMENT OF H.H. THE NIZAM OF HYDERABAD'S GOVERNMENT.<sup>1</sup>

SURGEON-LIEUTENANT-COLONEL LAWRIE'S report states that at the close of the previous year, 1299 Fasli, the number of students on the Register of the Medical School was seventy-nine, and that during the session 1891-92 (1300 Fasli) the total number of students on the roll was eighty-nine.

"The Medical School buildings were vastly improved during the year by additions made to them by the British Government. Three commodious lecture rooms were constructed in one handsome block built of granite, and were opened at the commencement of the school session on June 6th, 1891. The old anatomical theatre and lecture room were converted into spacious and well-lighted dissecting rooms, and water was laid on throughout the whole of the school premises from the waterworks of the Residency Bazaars. A large room was built on to the old anatomical lecture room and fitted for a students' library and dining room. A new and convenient room for carrying on animal vaccination from the calf was also constructed and proved a great boon. For the previous five years animal vaccination has been carried out in Hyderabad in accordance with the method of the London Local Government Board; the accommodation both for animals, patients and staff has been insufficient. The work was therefore carried on under extraordinary difficulties, which have disappeared with the opening of the new premises. A new school museum and chemical laboratory were designed by His Highness's Public Works Department in the year 1299 Fasli. They have not been built as the requisite funds have not been provided by his Highness's Government. These additions are urgently needed to complete the school buildings. .... The usual grants of the British and Nizam's Governments were fully utilised during the year, and the library and museum have been kept well supplied with new books, periodicals and appliances."

Under "Hospitals and Dispensaries," Surgeon-Lieutenant-Colonel Lawrie says: "During the prevalence of cholera in Hyderabad, towards the close of the year, four temporary dispensaries were opened in different quarters of the city, and were much appreciated by the poor. The scope of these dispensaries was not confined to the special disease which had called them into existence; but with the subsidence of the cholera epidemic Government directed that only two should be maintained for a year, and that tentatively. .... Considering the density of the population of the city and the distance of many of the most crowded parts from the Afzul Gunj Hospital, which is the only general hospital to which the sick poor can resort, two dispensaries are quite inadequate for the needs of the inhabitants of Hyderabad. The suburbs, which are scattered over a wider area but have a smaller population, contain 7 dispensaries." The number of patients treated in all the "Civil Hospitals" in the Dominions during the year was in excess of that of the previous year by 49,602. The number of deaths was 339, as compared with 277 of the year before. Of the numbers treated in Fasli 1301, the city hospitals returned 108,518 out-patients and 1955 in-patients, the districts 276,142 and 2314 respectively. 20,111 operations were performed during the year.

It is stated that the number of successful vaccinations performed during 1891 was 76,880. Only one of the four divisions of His Highness's Dominions—viz., Gulburga—is provided with an inspector of vaccination.

"During the year under report the supply of lymph was kept up by means of seventy-four calves; 2167 vaccinations were performed direct from the animals, of which 95.2 per cent. were successful, and lymph was supplied in capillary tubes to every vaccinator in the Dominions and to anybody else who applied for it. The transfer of the vaccination staff in the districts to the control of the revenue officials has been

productive of benefit and has secured, as was anticipated, the active co-operation of the revenue authorities.

"In the Afzul Gunj Hospital the number of in-patients, not including the Zanana department, treated during the year 1890 Fasli (1891) was nearly double the average annual number treated up to 1296 Fasli (1886). In 1885 the number of in-patients was 900, including the Zanana department; in 1891 it was 1794 exclusive of the Zanana department. The principal diseases for which patients were admitted were fever and dysentery. The number of fever cases admitted was 884 with 15 deaths; and there were 210 cases of dysentery with 71 deaths. All the dysentery cases which terminated fatally were suffering from the chronic form of the disease. They were, as a rule, brought to the hospital in the last stages of exhaustion and emaciation and nothing whatever could be done to benefit them.

"In the hospital 888 major and 6716 minor operations were performed during the year. In the year 1884 (1292 Fasli) there were 140 major and 1100 minor operations. The increase in the number of operations during the last seven years is due in a great measure to the free and safe use of chloroform. Formerly patients dreaded chloroform more than the operation itself and the sight of the chloroform bottle was generally the signal for the patient to bolt.

"Twenty-six cases of abscess of the liver were operated on by aspiration and antiseptic incision during the year 1891. Of these cases four died."

Dr. Lawrie gives a table to show the method of treatment and the results in the twenty-six cases. He adds:—

"The table shows in the most remarkable manner the value of aspiration in liver abscess. The rule in the Afzul Gunj Hospital is to aspirate all cases of abscess of the liver unless the pus is pointing at the surface, and many cases are cured in this way without exposure to the risk of an incision. If incision subsequently becomes necessary, the previous aspiration of the abscess is not found to prejudice the patient's chance of recovery. I may add that tartar emetic is used very freely with excellent results, in large and small doses, in all cases of liver abscess which are not of specific or septic origin."

Dr. Lawrie would appear to be strongly in favour of the treatment of organic stricture of the urethra by Holt's method of dilatation, employing a modified form of dilator designed by himself and manufactured by Messrs. Arnold and Sons. He remarks, "Under no circumstances whatever is *internal urethrotomy* a justifiable operation. It is an unsurgical and unscientific procedure which ought to be banished altogether from practice."

The use of antimony in frequently repeated small doses in mucous diarrhoea depending on catarrhal inflammation of the small intestine in children is alluded to in the report.

"We now," it proceeds, "use antimony in combination with the liquid extract of coto in this disease with very satisfactory results. The extract of coto appears to be almost a specific in acute enteritis, nearly as much so as ipecacuanha is in acute dysentery. In young infants of four or five months old the extract of coto may be given in five minim doses every hour, made up with the mucilage of yusut root instead of water. Two or three minims of antimonial wine are added to each dose if the temperature rises above 101° F. Surgeon-Lieutenant-Colonel Ross, who was formerly civil surgeon of Delhi, first called my attention to the value of coto in mucous diarrhoea, and, judging from my own experience of its beneficial action, it ought to be very widely known. No disease is more common among European children in India than acute enteritis and it causes an immense number of deaths every year. It is comparatively rare among Hindu and Mahomedan children. I believe this comparative immunity of Indian children is largely due to their habitual use of opium."

On the subject of opium Dr. Lawrie states his opinion that opium eating or smoking to excess is very uncommon in India. "I came out to India twenty years ago with violent prejudices against opium, which it took a long time to uproot. If opium eating is a vice, it is not to be compared in the harm it does with alcohol. Alcohol destroys the health and leads to crime; opium does neither the one nor the other. All men, and more especially all women, in health are much better without alcohol than with it; but I very much doubt if the same can be said in India about opium. On the contrary, an immense number of people in this country owe their health to opium, and would not only fall an easy prey to disease but would actually suffer in general health if they did not take it."

Dr. Lawrie gives some interesting particulars of the practice of midwifery and of diseases of women and children in the city of Hyderabad, where it is almost entirely in the hands of uneducated dhais:—

"To give an adequate idea of the barbarities habitually practised by these women is impossible. We are only able to judge of a few of them by the cases which from time to time came under our notice. In midwifery the treatment they adopt for cases of hard presentation is either to take a wisp of dry grass and set fire to it and burn the child's hand in order to make it withdraw it into the uterus, or else to wrench it off. If post-partum hemorrhage occurs the patient is made to stand up against a wall and an old woman butts at her abdomen with her head, like a goat. Numbers of cases of peritonitis and injury of the abdominal and pelvic viscera produced in this way come under our observation every year. The city dhais (midwives) have a superstition that breech presentations foreshadow evil to themselves and hence the child is always born dead from asphyxia in breech cases. The manner in which counter-irritants are employed in the shape of the actual cautery and powerful corrosives like the marking nut is truly shocking.

<sup>1</sup>Annual Report for Fasli 1300, by Surg.-Lieut.-Colonel E. Lawrie, M.B., Residency Surgeon, Hyderabad.

Hundreds of young women are mutilated and die, or are rendered unfit for further existence as married women, by sloughing and faulty cicatrization of the external organs of generation, owing to the application of the cautery and the marking nut.

"One of the commonest diseases in Hyderabad is supposed, according to the uneducated hakims who flood the city, to be dislocation of the navel. So firmly rooted is the idea that this is a real disease that patients who have severe stomach-aches and are persuaded that they are suffering from dislocation of the navel, will submit cheerfully to the most painful treatment for its reduction. Quite recently a patient who was suffering from what was said to be an unusually intractable form of dislocation of the navel, was so roughly pulled about by means of a rope passed round his waist and fixed securely by the ends to two pillars that he died of rupture of the spleen."

The two principal events of interest during the year are stated to have been the visit of the Leprosy Commission to Hyderabad and the completion of the report of the Hyderabad Commission on Chloroform. The Leprosy Commission were the guests of His Highness' Government. One case was shown to the commission which Dr. Lawrie thinks ought to have gone far to convince them that the bacillian theory of leprosy is untenable.

"A sepy in the regular troops was admitted into the Afzul Gunj Hospital, while I was in England on privilege leave, on account of anæsthetic leprosy of the whole of the right ulnar area, which, owing to the loss of power, prevented him from using his right hand. He could not cock the hammer of his rifle or pull the trigger. In my absence the operation of nerve stretching was performed, and a portion of diseased tissue from the neighbourhood of the ulnar nerve was submitted to microscopic examination, and found to contain the bacillus leprose (?) in large numbers. On my return from leave I found a note to the effect that there was no improvement whatever in the patient's condition. The ulnar nerve was enormously thickened and there was considerable inflammatory thickening of the lymphatics in its neighbourhood. The patient was therefore again placed under chloroform and a fresh incision was made, exposing the ulnar nerve for six or eight inches as well as the deep parts of the former incision. The previous incision was found to lead into a nearly dried up abscess cavity in connection with the lymphatic gland above the internal condyle; the ulnar nerve was intact. The thickened part of the ulnar nerve was now laid freely open throughout its entire extent and a quantity of brownish granular material was removed from its interior. When every particle of this deposit had been scraped away the wound in the nerve was sutured with catgut, and the external wound in the skin with horse-hair. The deposit taken from the nerve was examined microscopically by Dr. Bomford, and no bacilli were found in it. When the Leprosy Commission came here this sepy was convalescent. He is now quite well and performing his duties. He can cock the hammer of his rifle and pull the trigger and the right hand is almost as strong as the left. Sensation is nearly completely restored. In this case the removal of morbid tissue containing bacilli caused no change in the patient's condition. But the removal of morbid tissue containing no bacilli, but which by pressure on the delicate nerve fibres had destroyed the function of the nerve, cured the disease. The bacillian theory of anæsthetic leprosy is in my opinion entirely destitute of foundation. Anæsthetic leprosy is a granulomatous disease of the nerves in and between the nerve fibres. All the symptoms such as the loss of sensation, the atrophy of the muscles, the sores and eruptions of the skin and the loss of tissue by ulceration and sloughing are merely the result of, and are fully accounted for by, loss of function from pressure in the affected nerves, which gives rise to profound alterations of nutrition in the parts the nerves supply. I have operated on the nerves in hundreds of these cases, and have cured a considerable number, and no bacilli have ever been found in any of them. The natives of Hyderabad regard leprosy as the fourth stage of syphilis. The difference between the two however is so self evident that it is surprising how this belief ever arose. If leprosy were a stage of syphilis it would be, as syphilis is, universal in Hyderabad; but it is by no means as common as syphilis, nor is it inoculable. There is little doubt that it is hereditary, and that though lepers may have healthy children, the majority of them must have tainted constitutions."

With regard to the Hyderabad Chloroform Commission Dr. Lawrie very justly and properly alludes to the fact that "the unexampled liberality of his Highness the Nizam has made it possible for the Hyderabad Commission, not only to carry on its investigations, but also to publish them to the world." We gladly avail ourselves of the opportunity of again expressing our own appreciation of H.H. the Nizam's princely and enlightened action in the interests of science. Dr. Lawrie is further of opinion that "this, however, is not sufficient, and if these investigations are to be made of permanent benefit to mankind—if, in fact, the use of chloroform as an anæsthetic is to be continued—the time has come for an interference on the part of the supreme and home Governments, who by means of a Royal Commission could authoritatively lay down the principles which should be followed, and thus remove this most important question from the field of professional controversy and jealousy." We are so anxious that the blessings of chloroform should be secured to the fullest extent for the general good of mankind that we gladly reproduce Dr. Lawrie's remarks and afford them all the publicity at our command. At the same time he will, we feel assured, pardon us if we take exception to the phrase "professional controversy and jealousy," and to the somewhat combative spirit which pervades his writings on this subject. There should be no such thing as polemics in science—no taking of sides or strong personal feeling,

but rather a patient and earnest searching after truth. The facts that Dr. Lawrie has done such great and good service in the past, is doing such admirable work at the present time, and has such excellent opportunities before him, cause us all the more to regret that he is so far carried away by his enthusiasm as to speak constantly of fellow-labourers in the field of science who happen to hold views not in accordance with his own as "our opponents." There must be no internal dissensions amongst those who fight for the same good cause; and we should be indeed glad to see a more wholesome attention being paid to "discipline" by all those who have buckled on their armour to take part in the righteous war which we would all fair wage against disease and suffering.

## THE BRITISH DENTAL ASSOCIATION.

The British Dental Association recently held its thirteenth annual meeting at Manchester. It was welcomed to that city by the mayor, who gave a reception in the Town Hall.

Mr. Smith Turner, the retiring president, was succeeded by Mr. Quinby of Liverpool. The reports of the executive showed the Association to be financially and numerically successful, and also that it had by its efforts caused some attention to be paid to the wants of the Navy from a dental point of view, but that the steps so far made were inadequate both to the wants of the service and to the opinion expressed by the dental profession.

The investigation into the teeth of school children is also bearing fruit and should lead to the appointment of a dental surgeon at all large schools.

The discussion on the best method of relieving crowding of the front of the mouth, whether by removal of the first molars or by extraction of the first or second bicuspid, was a valuable contribution to dental knowledge, the general result being that when any choice were possible the bicuspid, as being nearest the deformity, should be sacrificed.

Some beautiful slides were exhibited on the screen, illustrating the micro-organisms of dental caries and phagocytosis. A large number of demonstrations of a purely technical character were given. The development in this direction is full of danger and should be carefully regulated; only original demonstrations should be admitted, and the ordinary methods of filling or crowning teeth which have no originality should be excluded.

A museum illustrating irregularities of the dental arch and abnormalities in shape and form of individual teeth was carefully prepared and much valued. A report which we understand is to be made should produce some valuable addition to knowledge on the questions.

The microscopic exhibition was exceptionally good and the organiser deserves much praise.

The social part of the meeting was very successful and the Association received every hospitality it could have hoped for. The garden party at Peel Park given by the Mayor of Salford, the conversation by the Manchester Odontological Society, and the entertainment by Mr. Quinby, the President, at the excursion to Buxton, were each in their turn only characteristic of that generous hospitality that is always found in the midlands. A large number of the medical practitioners of the district were present at the dinner.

## LUNACY INQUIRY AT DOVER.

An inquiry was held at the Lord Warden Hotel, Dover, on the 30th ult., before Master Bulwer, Q.C., and a special jury of twenty-three, under a commission and order of the Lords Justices of Appeal as to the alleged insanity of the Rev. F. J. Ramsden of Uffington, near Stamford, Lincolnshire.

The medical and other evidence in the case was not called in question. Mr. Ramsden, jun., gave evidence to the following effect. His father in 1875 had an accident in the hunting field, injuring his spine. Previously to that he was perfectly sound in mind and always conducted himself as he ought to do. Some months after the accident he had a paralytic seizure, and it was at once manifest that his mental powers had been impaired. By the seizure his face on one side was drawn, and he had a difficulty in his speech. After

this he took no notice whatever of his affairs. He kept no account and would frequently carry large sums of money about with him. He would also order a quantity of furniture, for which he had no use whatever. Sometimes witness countermanded the order; at other times he had great difficulty in doing so. His father also sent home large quantities of fish, flowers, fruit and other articles. The food was given to the dog, but sometimes there was such a large quantity sent that it could not eat it, and they had to bury it. His father then had a craving for drink, which increased in 1889, and he frequently got intoxicated. He had kept no account in bulk as to the extent of his father's extravagance, but it had been a large sum, and considerably over £2000 beyond his income, which was about £2000 a year. His conversation at this time was very rambling. He could not talk coherently for any length of time. In the spring of 1891 he was taken to Tunbridge Wells, and after that to St. Leonards. His father treated his mother and himself and sisters with general unkindness and utterly neglected them. He also used very strange language towards them. On some of the hottest days in summer he would insist in making large fires all over the house. While at St. Leonards he wanted to walk about during the daytime with only his night-shirt on and a dress-coat over it. His memory had failed him, more especially since 1889. He had seen his father smoking his fingers and puffing under the impression that they were cigars, and they frequently took them out of his mouth. It was found necessary to have an attendant with him. He would sometimes go to bed with all his clothes on, and had on more than one occasion taken a red-hot poker to his bedroom in order to keep the fires alight. It was found necessary to send him away somewhere, and he was sent to a place near Brussels, to the asylum there, on May 24th, 1892. Witness accompanied his father, and had since corresponded briefly. Witness was the means of saving the sale of a large number of stocks.

The evidence of a number of medical men, both English and Belgian, who had been consulted about the case went to show that Mr. Ramsden suffers from progressive general paralysis of the insane from which he is not likely to recover, and that he is totally incapable of managing his own affairs.

The Master briefly summed up the facts. He said it was a great satisfaction to have heard that it was not drink that always caused these cases of insanity. In this case it was the disease that caused the craving for drink. The law was such now that it provided for cases of this kind, and every sixpence was taken care of.

The jury at once returned a verdict that they were of opinion that the Rev. F. J. Ramsden was of unsound mind, and the Master made the order accordingly.

## THE EXHIBITS AT NOTTINGHAM.

To the list of noteworthy exhibits in the museum at the meeting of the British Medical Association at Nottingham which we published last week, may be added the following which we were obliged by considerations of space to hold over:—Messrs. Lynch and Co. had an unusually large and varied show of surgical instruments and appliances of all kinds, showing modifications of instruments and adaptations to various forms of disease. Messrs. Coxeter and Son, had a very important assortment of improved surgical and electrical apparatus; while Messrs. Salmon, Ody and Co., exhibited some excellent single and double trusses, artificial limbs and specimens of all kinds of instruments used in orthopedic surgery. Messrs. Mayer and Meltzer had a large exhibit of instruments, showing recent improvements in apparatus for the treatment of diseases of the ear, nose and larynx. Among other miscellaneous instruments were their nickel-plated metal splints. Messrs. Richardson and Co., besides having a large display of elegant drugs in all forms, showed medicine chests in wood and leather, and also the dispensing cabinet which we described last year. Messrs. Arnold and Son had also a very large exhibition of new and improved instruments, among which was a new form of a tonsil guillotine. Messrs. S. Kutnow and Co. had an excellent display of drugs, including their anti-asthmatic powder and their improved effervescent Carlsbad powder;

while Messrs. W. R. Warner and Co. enlisted the attention of the members by their exhibits of antalgic saline, bromosoda, ingluvin and pills and granules. Messrs. Johnson and Johnson showed their modifications of dressings and surgical appliances of all kinds, particularly those of an antiseptic and absorbent nature. Messrs. Armour and Co. exhibited their well-known pepsine preparations and beef juices. The Maltine Manufacturing Company had a large display of maltine preparations and beef peptones. In this department we also noted the exhibits of the Bovinine Company, and of Messrs. Wyeth and Brother. Messrs. Christy and Co. showed improvements in the manufacture and preparation of oiled silk. They had also a show of spring bougies. The Palma Christi (Standke) a preparation of castor oil, devoid of nauseating or emetic properties, attracted a good deal of attention.

## VITAL STATISTICS.

### HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns 6605 births and 3517 deaths were registered during the week ending Aug. 13th. The annual rate of mortality in these towns, which had been 17·3 and 17·4 per 1000 in the preceding two weeks, further rose last week to 18·0. In London the rate was 17·4 per 1000, while it averaged 18·4 in the thirty-two provincial towns. The lowest rates in these towns were 12·5 in Wolverhampton, 13·7 in Sunderland, 14·0 in Huddersfield and 14·2 in Cardiff; the highest rates were 21·5 in Salford, 22·4 in Bolton, 22·8 in Manchester, 23·3 in Liverpool and 24·2 in Burnley. The 3517 deaths included 681 which were referred to the principal zymotic diseases, against 585 and 623 in the preceding two weeks; of these, 364 resulted from diarrhoea, 121 from measles, 62 from whooping-cough, 52 from scarlet fever, 45 from diphtheria, 35 from "fever" (principally enteric) and 2 from small-pox. These diseases caused the lowest death-rates in Huddersfield, Newcastle-upon-Tyne, Swansea and Gateshead, and the highest rates in Liverpool, Plymouth, Bristol, West Ham, Bolton and Portsmouth. The greatest mortality from measles occurred in Croydon, Sunderland, Oldham and Bristol; from scarlet fever in Cardiff and Plymouth; from whooping-cough in Birkenhead, Preston, Burnley and Portsmouth; and from diarrhoea in West Ham, Portsmouth, Leicester, Burnley, Liverpool and Bolton. The 45 deaths from diphtheria included 35 in London and 3 in Manchester. One death from small-pox occurred in Halifax and one in Sheffield, but not one in any other of the large towns. Five cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 3 in the Highgate Small-pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 3088, against numbers increasing from 1226 to 2995 on the preceding twenty Saturdays; 376 new cases were admitted during the week, against 382 and 346 in the preceding two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 185 to 143 in the preceding six weeks, rose to 174 last week, but were 15 below the corrected average. The causes of 59, or 1·7 per cent., of the deaths in the thirty-three towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Bolton, Bradford, Leeds, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Halifax, Newcastle-upon-Tyne, Preston, Oldham and Burnley.

### HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·5 and 18·5 per 1000 in the preceding two weeks, declined again to 17·0 per 1000 during the week ending Aug. 13th, and was 1·0 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 14·1 in Leith and 14·9 in Edinburgh to 19·8 in Greenock and 20·6 in Perth. The 474 deaths in these towns included 32 which were referred to diarrhoea, 19 to measles, 16 to whooping-cough, 13 to scarlet fever, 7 to "fever," 6 to diphtheria, and not one to small-pox. In all, 93 deaths resulted from

these principal zymotic diseases, against 54 and 83 in the preceding two weeks. These 93 deaths were equal to an annual rate of 3.3 per 1000, which was 0.2 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhoea, which had been 10 and 31 in the preceding two weeks, rose last week to 32, of which 20 occurred in Glasgow and 5 in Greenock. The deaths referred to measles, which had been 19 and 23 in the previous two weeks, were 19 last week, and included 13 in Glasgow and 5 in Edinburgh. The 16 deaths from whooping-cough showed an increase of 5 upon the number in the preceding week, and included 9 in Glasgow and 3 in Edinburgh. The deaths from scarlet fever, which had been 3 and 8 in the preceding two weeks, rose to 13 last week, and 11 of these occurred in Glasgow. The 6 deaths from diphtheria were one less than the number last week, and included 3 in Glasgow and 2 in Paisley. The deaths referred to diseases of the respiratory organs in these towns, which had been 114 and 77 in the preceding two weeks, further declined to 74 last week, but exceeded by 20 the number in the corresponding week of last year. The causes of 27, or nearly 6 per cent., of the deaths in the eight towns last week were not certified.

#### HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28.3 and 21.5 per 1000 in the preceding two weeks, was 21.6 during the week ending Aug. 13th. During the first six weeks of the current quarter the death-rate in the city averaged 22.9 per 1000, against 17.9 in London and 16.1 in Edinburgh. The 145 deaths in Dublin during the week under notice showed an increase of one upon the number in the preceding week, and included 6 which were referred to diarrhoea, 5 to measles, 2 to whooping-cough and not one either to small-pox, scarlet fever, diphtheria or "fever." In all, 13 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1.9 per 1000, the zymotic death-rate during the same period being 3.2 in London and 2.6 in Edinburgh. The fatal cases of measles, which had been 8 and 6 in the preceding two weeks, declined last week to 5. The deaths from diarrhoea, which had been 3 and 5 in the preceding two weeks, rose to 6 last week. The 145 deaths registered last week in Dublin included 29 of infants under one year of age and 32 of persons aged upwards of sixty years; the deaths of infants showed an increase of 3 and those of aged persons an increase of 6 upon the numbers in the previous week. One inquest was held and 1 death from violence was registered; and 41, or 28 per cent., of the deaths occurred in public institutions. The causes of 7, or about 5 per cent., of the deaths in the city last week were not certified.

## THE SERVICES.

#### VOLUNTEER MEDICAL OFFICERS.

A Volunteer Medical Officer writes:—"Under existing Regulations Volunteer Medical Officers are required to serve fifteen years before becoming eligible for Field Rank. whereas their brethren in the Militia and Regulars (not counting the Army Medical Reserve) are granted the same after ten or twelve years' service respectively, which appears to be rather unfair to those who give all and receive nothing. Besides this there are many Volunteer Medical Officers who have in previous years held combatant commissions, none of which time is allowed towards promotion. Mindful of all you have done in the past through your columns for the Military Medical Service, it is to be hoped that you will not withhold a helping hand to the junior branch of the service by getting the time for promotion put upon an equality with their comrades in the senior services and by obtaining recognition of *all* commissioned service, whether combatant or otherwise, towards promotion."

#### ASSISTANT PROFESSORSHIP OF MILITARY HYGIENE AT NETLEY.

We congratulate the army and the Medical School at Netley on the appointment of Surgeon-Captain Firth, F.R.C.S. Eng., to the post of Assistant Professor of Military Hygiene. The officer in question has shown by his prize essays in connexion with the Alexander Memorial Fund, and

his contributions to the army medical reports, that he possesses scientific qualifications of a high order, and we feel confident that he will prove an acquisition to the school.

#### INDIAN TROOPSHIP PROGRAMME.

The programme of movements of Her Majesty's Indian troopships for the season 1892-93 has been published. It is, of course, extremely difficult to arrange the movements of a large number of troops with a limited number of steamers at disposal so that all the men should arrive in India and at home at the most favourable season. As regards those outward bound, it is desirable that young soldiers should not arrive at Bombay too early and highly advisable that they should not arrive too late in the season—that is to say, at the beginning of the hot weather there. We notice that the first outward steamer leaves Portsmouth on September 3rd and arrives in India at the end of that month, which is the very earliest date that can be deemed desirable; the last steamer arrives at Bombay on March 27th, which, as far as considerations of health are concerned, is late for the landing of a number of young soldiers for their first time in India, for they will almost immediately have to encounter the hot season there, and the change imposes a severe test on the constitution. But we suppose that with the amount of transport at command it is very difficult, if not impossible, to arrange it otherwise. We hope that, as far as practicable, the newly-arrived troops will be sent to the hills. As regards the homeward-bound troops, on the other hand, it is important that invalids and sickly men should arrive in this country so as to escape the rigours of this climate in winter and obtain all the benefit they can from the cool season of the climate they are leaving; and it is only right to add that the arrangements are, we believe, made, as far as practicable, with this end in view.

#### AFGHANISTAN AFFAIRS.

There are a number of officers belonging to the medical staff and Indian medical service who retain a lively, and probably some of them not an altogether pleasant, recollection of Afghanistan from their having taken part in one or other of the expeditions into that country during the last war. Service in Afghanistan is attended with a good deal of sickness and hardship, and many medical officers had a very rough time of it in those wars. It is just as well, perhaps, that the Ameer has requested that the special mission under Lord Roberts should be deferred for the present. Things are evidently very unsettled in Afghanistan—the tribes are opposed to one another and to the Ameer's rule, as well as extremely jealous of any interference on the part of the British.

#### MOVEMENTS OF THE MEDICAL STAFF.

Surgeon-Captains M. O'D. Braddell is transferred from the Station Hospital, Sheffield, to Derby, for temporary duty, vice Surgeon-Lieutenant-Colonel Francis, M.M.S. Surgeon-Captain Dixon proceeds from Aldershot to the North-Western district on temporary duty. Surgeon-Captain Kirkpatrick has returned to the Station Hospital, Glencarse, from duty at Lanarkmuir. Surgeon-Captain Woods has proceeded from Weymouth to Portland, for duty.

#### ARMY MEDICAL STAFF.

Brigade-Surgeon-Lieutenant-Colonel John Stannard MacAdam is placed on retired pay (dated Aug. 3rd, 1892). The undermentioned Surgeon-Lieutenant-Colonels to be Brigade-Surgeon-Lieutenant-Colonels (dated Aug. 3rd, 1892):—William F. Stevenson, vice J. S. MacAdam, and Robert N. Macpherson, vice W. Johnston, M.D., retired. Surgeon-Lieutenant-Colonel Charles Barromeo Jennings is placed on temporary half-pay on account of ill-health (dated Aug. 10th, 1892). The undermentioned Surgeon-Captains to be Surgeon-Majors (dated July 31st, 1892):—George H. Sylvester, F.R.C.S. Eng.; William J. Macnamara, M.D.; Daniel O'Sullivan, F.R.C.S.I.; Edwin O. Milward; Chas. R. Woods, M.D., F.R.C.S.I.; Michael F. Macnamara, F.R.C.S.I.; John O. G. Sandiford, M.D.; Robert L. Love, M.D.; Henry W. Murray, M.B.; Michael W. Kerin; Alfred Peterkin, M.B.; James Harran; Edwd. L. Maunsell; Wm. Heffernan; Ronald W. E. H. Nicholson; Jas. G. W. Crofts; William Dugdale; Delaware L. Irvine; Edwd. R. Cree; Maurice O'C. Drury; James H. Nicholas; Denham F. Franklin, F.R.C.S. Edin.; and Herbert Saunders. The undermentioned Surgeons on Probation to be Surgeon-Lieutenants (dated July 27th, 1892):—Harry Alexander Hinge; James Gibson McNaught, M.B.; Hubert Alaric Bray; Thos. McDermott, M.B.; Edwd.

Wheeler Slayter, M.B.; Hugh Stanley Thurston; Lancelot Paxton More, M.B.; Charles O'Connor Hodgkins; Arthur Frederick Tyrrell; William Phayer Ryall; Theophilus Percy Jones, M.B.; George Stanley Walker, M.B.; William Johnson Smyth, M.D.; William Douglas Erskine, M.B.; Albert George Thompson, M.B.; Alexander Jasper Chambers; George Abraham Moore, M.B.; Richard Crump Lewis; Reginald Francis Edmund Austin; Henry Wm. Hutchinson O'Reilly, M.B.; Nicholas Marder; Edgar Hunt Condon, M.B.; Gerald Stewart Mansfield, M.B.; Frederick George Faichnie; and Harold William Kingcombe Read.

Surgeon-Major Stephen Massett Webb, M.D., late of the 36th and 23rd Regiments, who died on the 3rd inst. at Plymouth in the sixty-fourth year of his age, obtained his appointment as an Assistant Surgeon in the Army on May 19th, 1854, and retired in July, 1876, with the rank of Surgeon-Major. He served at the siege of Sebastopol during the winter of 1854-55, and was awarded the medal with clasp and Turkish medal.

NAVAL MEDICAL SERVICE.—The following appointments have been made:—Surgeons William H. Norman to the *Blonde*, John S. Fogerty, M.D., to the *Banterer*, and Fredk. W. Parker to Plymouth Hospital (all dated Aug. 13th, 1892).

VOLUNTEER CORPS.—*Rifle*: 1st (Hertfordshire) Volunteer Battalion, the Bedfordshire Regiment: Surgeon-Captain D. B. Balding (Honorary Surgeon-Major) to be Surgeon-Major (dated Aug. 13th, 1892).—1st Volunteer Battalion, the Gordon Highlanders: George Maitland Edmond, M.D., to be Surgeon-Lieutenant (dated Aug. 13th, 1892).

## Correspondence.

"Audi alteram partem."

### "ASPIRATION IN PNEUMOTHORAX."

To the Editors of THE LANCET.

SIRS,—I have read with great interest Professor Gairdner's further communication on the above subject in your issue of July 30th, and regret to find that he still considers the treatment I employed "a dangerous error in practice." Dr. Gairdner states that on the removal by aspiration of intrapleural pressure, which in the case related was the same as that of the atmosphere, there is a reversal of pressure, which, instead of being from without, is now from within the lung. To this it may be replied that the intrapulmonary pressure is constant, being the same as that of the atmosphere, as long as tranquil breathing is maintained. Consequently air does not "rush in force along the still pervious bronchi," and far less is there a positive pressure in the lungs such as is present in the example cited, that of a lung placed in water and forcibly inflated by air blown in through a bronchus. This last illustration is applicable only when cough is present—that is to say when the principle of the force-pump is brought into action by forcibly compressing the lungs, and at the same time closing the glottis. In the case related there was no cough during or after the aspiration. Dr. Gairdner's argument is based on the supposition that the pleural cavity was suddenly emptied of air, and the collapsed organs suddenly re-expanded, and as this was far from being the case it may be as well to describe the method employed more minutely. A very slight exhaustion of the receiving bottle was made, the connection was opened to a small extent, and a short puff of air was heard to enter the bottle. The heart and pulse were then examined and the process repeated, until from the condition of the pulse and respiration it was concluded that the immediate danger of syncope had been averted. The dangers anticipated by Dr. Gairdner are theoretical, for he has never aspirated in pneumothorax, but instead he is content to argue from the occurrence of pneumothorax after aspiration in pleuritic effusion. Is this at all a parallel case? The presence of air in the pleural cavity during or after aspiration in simple pleuritic effusion is usually ascribed, not to a rup-

ture of the visceral pleura, but to the entrance of air from outside through the parietal pleura, owing to a faulty apparatus or a faulty operator, or both.

I am, Sirs, yours obediently,  
Carlton-hill, N.W., Aug. 1st, 1892. G. A. SUTHERLAND.

To the Editors of THE LANCET.

SIRS,—In your issue of July 30th Professor Gairdner condemns this operation as "a dangerous error in practice." His chief objection is the oft-quoted one, that aspiration in pneumothorax tends to reopen the fistulous track, which is in process of closure by lymph deposit. He says:—"I am not setting it forth as a theoretical risk, but as one which I have known to occur; not indeed in pneumothorax—for I have never aspirated in pneumothorax—but in pleuritic or empyematous effusions. I have known the aspiration of these immediately followed by pneumothorax, indicated by a succussion sound which was not present before the operation." In the absence of further evidence, and as Professor Gairdner expressly states that these were not primarily cases of pneumothorax, I fail to see that the presence of a succussion sound after aspiration for fluid is proof that a "kindly veil of lymph," protecting an opening from the lung into the pleura, has been torn. The succussion sound might equally well be due to the entrance of air into the pleural cavity from outside, during or at the end of aspiration, an accident which frequently attends aspiration, which always occurs after free incision, and which is unimportant provided that the air is pure.

If, on the other hand, a true pneumothorax in cases of effusion was produced in the manner which Professor Gairdner describes he would be justified in condemning aspiration for fluid as strongly as he condemns aspiration for air. Professor Gairdner further denies that aspiration in pneumothorax can produce re-expansion of the collapsed lung. But aspiration in Dr. Sutherland's case was followed at once by re-expansion of the lung and return of the heart and mediastinum to their normal position, with prompt relief from the symptoms which threatened death. I am far from advocating the indiscriminate use of aspiration in all cases of pneumothorax, but as I believe that the object of treatment should be to procure re-expansion of the collapsed lung and relief to the heart, which threatens to fail from its sudden malposition, so I think it is justifiable in urgent cases where simple puncture is of no avail to aspirate even at the risk of reopening the fistula. The death-rate from pneumothorax is too high to warrant us in adopting the expectant method of treatment. At the same time if the urgent symptoms are relieved by puncture I should be only too glad to leave well alone.

I am, Sirs, yours truly,  
LEONARD G. GUTHRIE.  
Upper George-street, W., Aug 7th, 1892.

### NOTIFICATION OF INFECTIOUS DISEASE.

To the Editors of THE LANCET.

SIRS,—You remark that "our first duty in the light of the requirements of the Act is to perfect our skill in diagnosis," and you lament an apparent increase of errors in diagnosis among the cases notified. Your suggestions in dealing with the means of improving the accuracy of our diagnostic faculty are good as far as they go, but the fact remains that as long as students are imperfectly taught the things relating to infectious diseases the results of their future attempts, by consultation and otherwise, to ensure accuracy in diagnosis are not likely to become more successful. It is by examination of the causes of imperfect instruction in diagnosis that the remedies for deficient skill may be found. Most truly do you say that the abolition of pupillage is one cause, but you might have gone a little farther and found more to say in this direction. Able students, just qualified, unless compelled by circumstances, avoid more and more the drudgery of private assistantship, and in this they are encouraged by the multiplied inducements held out to them of late years to take junior appointments about hospitals. These appointments afford valuable instruction, but not in that sort of knowledge which is required in general practice, especially in the matter of these infectious diseases; so that from year to year more and more doctors, untrained either by pupillage or private assistantship, find themselves struggling at a disadvantage with the exactions of compulsory notification. You admit that general hospitals show an "increasing ten-

dency to exclude" these diseases, but seem to think that the admission of students to the hospitals of the Asylums Board may compensate for this drawback. If the regulations I saw last year regarding the attendance of students at these hospitals continue in force, I make bold to doubt whether many students can be attracted to avail themselves of this privilege. I find that students are now required by the English Conjoint Board to produce, besides various certificates from their general hospital, evidence of instruction by a teacher of vaccination, and of attendance at a fever hospital and a lunatic asylum, as well as at an eye hospital if the general hospital possess no special eye department. This conjures into the mind's eye a picture of the student, already harassed by frequently recurring examinations and constant attendance at lectures, classes &c., for certificates, further wasting his time in a weary tramp from one (special) institution to another in search of yet more certificates. In fact, Sirs, students are so pestered with examinations and official preparation for them that they cannot be expected to devote their time to any other thing, and as they are not likely to be set down to the diagnosis of cases of diphtheria and small-pox in the examination room, they will pay but little attention to such diseases.

The causes of want of skill in diagnosis of infectious diseases are, then, besides abolition of pupilage—first, the growing unpopularity of private assistantship, to some extent favoured by multiplication of junior hospital appointments; second, the elevation of success at examinations to the first and almost only place among objects to be aimed at by the student; and last, but not least, the unhappy increase of special hospitals, instead of increase of special departments and wards of general hospitals, fruitful of many abuses, but of none more disastrous than its narrowing influence on the education of students. The remedy for this and other evils is to be found in a radical change in medical education and hospital organisation. We have got on to a bad road, and every further step involves us more deeply among the stones and mire.

I am, Sirs, yours obediently,  
Derby, Aug. 10th, 1892. G. H. MILNES, M.D. Cantab.

\* \* Pressure on our space has obliged us to omit the opening paragraphs in this letter, in which Dr. Milnes laments the passing of that portion of the Notification Act which throws the duty on the medical practitioner.—ED. L.

*To the Editors of THE LANCET.*

SIRS,—Kindly allow me to call your attention to a case which may be of some interest to the medical profession. The facts are these:—

On July 29th a lad, John Weston, aged sixteen, was brought to me at the Queen's Jubilee Hospital by the mother, suffering from diphtheria, for which I duly filled up the notification form and at once handed it to the secretary of the hospital, requesting him to attend to it immediately. The secretary at once telephoned to the Metropolitan Asylums Board, Norfolk-street, Strand, giving them the full particulars of the case, and inquired whether he should "forward the notification as usual," being told in reply, "No, hand it to the nurse when she calls for the case." This was done shortly after. On Aug. 4th a letter was received from Mr. J. E. Cooney, the medical officer of health for Fulham, stating that no certificate had been received, and in reply to which I requested the secretary to say I should be happy to send a duplicate if desired, notwithstanding the fact that the notification had been sent direct to the Metropolitan Asylums Board as directed by them. Mr. Cooney's reply to my letter was a police court summons taken out before Mr. Curtis Bennett. The summons was heard to-day, when Mr. Curtis Bennett held that by handing the notification to the secretary of the hospital I was disobeying the Act and imposed a fine upon me of 10s. and costs. It is thus held that a medical man is compelled to either post or deliver the notification himself in person, and failing to do so is responsible. I contended that, having handed the notification to the secretary, a responsible hospital official, who, acting rightly or wrongly, but at all events according to the directions of the Metropolitan Asylums Board, handed the notification to a Metropolitan Asylums Board nurse, my duty of "sending" was properly carried out. As a matter of fact, at the time of certifying I left my clinique to hand the secretary the notification at once, so that no time might be lost, and I can-

not help regarding the action taken as being discourteous, especially after my offering to send a duplicate notification if desired.

I am, Sirs, yours truly,  
RAYNER D. BATTEN, M.D., B.S. Lond.  
Finsbury-circus, E.C., Aug. 12th, 1892.

SCARLET FEVER.

*To the Editors of THE LANCET.*

SIRS,—A short time since I received a statement from Mr. Munro, the sanitary inspector of the Enfield Board of Health, on the results obtained from supplying the eucalyptus disinfectant for inunction in fifty-four cases of scarlet fever amongst the poor in houses where there were other children. Directions were given for the inunction to be carried out as advised by me in my paper on Disinfection of Scarlet Fever, and although some of the mothers did not do it efficiently because the children objected to the smell, forty-three of the primary cases were not followed by a second. In the other eleven three occurred on the sixth and seventh days after the first, and were most probably infected before the use of the disinfectant; the other eight occurred from two to eight weeks after the first. Most of these may have been infected from other sources, as an epidemic was then prevailing, and all of them occurred after the disinfectant was discontinued. The above shows a percentage of twenty fresh cases occurring in houses within eight weeks where the eucalyptus was used, but with little medical supervision. At Nottingham Dr. Boobyer stated lately that in 100 primary hospital cases 23 per cent. additional cases occurred in the houses from which they were removed within three weeks; and for every 100 home cases treated, nearly 60 per cent. additional ones occurred. The superiority of this imperfect trial of disinfection by eucalyptus inunction is thus shown to be 40 per cent. better than any other form of house disinfection and 3 per cent. better than that obtained by prompt removal of the cases to hospital and the disinfection of their homes. If the Enfield cases were limited to those that occurred within four weeks after the first (as there was one at five weeks' and two at eight weeks' interval) then only 14 per cent. of additional cases occurred, or 9 per cent. better than under the present system of removal; and if the three already infected cases are also excluded, the fresh cases are reduced to 9 per cent. From all the reports that I receive from medical men who carefully carry out this method of disinfection on the cases and on the children that have been exposed to the infection it is seldom that a second case occurs, and from my own experience a second case does not occur except in those already infected.

I am, Sirs, yours faithfully,  
Teddington, Aug. 15th, 1892. J. BRENDON CURGENVEN.

ANTHROPOLOGY FOR MEDICAL STUDENTS.

*To the Editors of THE LANCET.*

SIRS,—I am glad to see Mr. H. Havelock Ellis suggests, in conformity with a resolution of the recent Congress on Criminal Anthropology, that anthropology should form a part of the professional training of medical students. From my twenty years' connexion with anthropological work I am convinced that anthropology would be a popular subject with medical men if they were taught its objects and methods when they were students. There is a great deal of good work being done by medical men which is practically lost to science for want of a central organisation to which it can be referred for examination and publication; and there is a good deal of work being done which is comparatively useless from a lack of elementary knowledge as to the methods, objects and work already done. The need for coördination in anthropological inquiries is shown by the unexpected, and I must add the improbable, results of Dr. Warner's inquiries into the prevalence of physical defects in children in different strata in society. His observations show a higher percentage of defects in the selected, well-nurtured and well-cared-for upper classes than among the poorer classes, whose children are subject to rickets, scrofula, bad or insufficient food and bad sanitary surroundings, results quite opposed to those obtained by the Anthropometric Committee of the British Association, as shown by its final report (drawn up by myself) published in 1883. Mr. Havelock Ellis refers to

various existing institutions where medical students might be taught elementary anthropology, but none of them are available for the purpose at the present time. A few years ago I drew up a scheme for such a school and submitted it privately to some of our leading anthropologists, but I received no encouragement; and later, when the laboratories at the Examination Hall of the College of Physicians and Surgeons were being organised, I suggested that room should be found for an anthropometric laboratory, but to no purpose, as in the present state of medical science it is useless to place the study of the whole living human being in rivalry with the study of a blood-corpuscle, a nerve cell or a bacterium. The museum of the College of Surgeons would be an ideal place for anthropological teaching, as Mr. Ellis suggests, but the present conservative council of the college is not likely to provide such instruction without a good deal of pressure from without. The Anthropological Institute is a learned society which is engaged in collecting and publishing the work of experts, and has no convenience or staff for giving elementary instruction; while the laboratory at South Kensington is rather a collection of models and new inventions which require the hand of the inventor to set them in motion. What is immediately wanted is a scheme showing the relation of anthropology to medical science. Mr. Ellis thinks anthropology would help the students of insanity and other diseases of the nervous system, and this is among the chief uses it has been put to; but it would be of still greater use to the students of public health, especially that branch of anthropology dealing with measurements which is known as anthropometry. Medical men are more immediately concerned with the variations of the complexion, of the senses and of the physical proportions of the body in civilised races and their relations to the conditions under which different classes live, and all these variations can be, and ought to be, defined by measurement; but prehistoric and antiquarian anthropology and the details of the habits and customs of savage tribes are only interesting indirectly to them as travellers or practitioners abroad. Criminal anthropology, about which we have heard so much lately, is based on measurements of healthy, and it may be degraded, but not diseased, individuals, and a comparison of them with other classes of society, especially the class from which they come. (Dr. Clouston, by the way, was in error when he said recently in Edinburgh that no attention had been given to the classes from which criminals come, as he will find if he consults the various reports of the Anthropometric Committee.) It is of little use, therefore, to write papers and make speeches on the desirability of including anthropology in our medical education to lecturers and examiners, who have already too much work on their hands to admit of their entertaining any change if they can possibly avoid it. What is wanted is that Mr. Havclock Ellis, Dr. Clouston and others, who have come to see the importance of such an addition to the medical student's studies, should draw up a scheme of what they want teaching, and submit it to the authorities most likely to carry it out. They must also be prepared to say what part of the curriculum can be omitted to make room for this new subject. Mr. Ellis suggests that botany might be left out, but botany has long since disappeared from the medical schools, and it should be, I think, the anatomy and physiology courses which should make room for anthropology. Might not sufficient time be carved out of that which is at present devoted to microscopic work? The student certainly should be taught that it is a whole living being, and not an infinite fragment of one, that he has to deal with in practice.

I am, Sirs, your obedient servant,

CHARLES ROBERTS, F.R.C.S.

Eccleston-street, W., Aug. 15th, 1892.

## THE CLOSING OF THE PUBLIC CATTLE DRINKING TROUGHS.

To the Editors of THE LANCET.

SIRS,—The confession of helplessness conveyed in the circular letter of Aug. 8th from the Secretary of the Metropolitan Drinking Fountain and Cattle Trough Association, stating that "the committee have reluctantly decided to close all their troughs in the metropolitan district for a period of two months" really publishes to civilisation the most scathing reproach on the public health sanitary arrangements of the present day. When we think that this relates

to the capital city of the nation which justly stands at the head of all nations for its sanitary appliances and regulations for the protection of the public health I feel that all sanitarians should consider themselves placed on their mettle to remove this reproach without delay. Horses and cattle will now be taken to the troughs attached to many public-houses, which, so far as I can see, are not constructed so as to afford any protection from the spread of the infectious diseases traceable to these troughs; the action therefore, of the committee of the Metropolitan Drinking Fountain and Cattle Trough Association will, it is to be feared, only tend to the spread of glanders, instead of its decrease. Having had, as sanitary officer of a large sanitary circle in India occasion to take special steps for the prevention of the spread of foot-and-mouth disease and glanders among the Government horses and cattle under circumstances which enabled me to exercise a complete supervision over these measures, I can state that, as the result of this practical experience, with a water supply such as is available in the metropolitan district, nothing is more simple than the construction and maintenance of a cattle drinking trough, at a very moderate cost, which will effectually remove the risks complained of as regards the spread not only of glanders but of foot-and-mouth and other infectious diseases. The present pattern of public cattle drinking troughs, though in some respects ill suited to meet the present emergency as regards the prevention of the spread of glanders can yet, I feel certain, by some slight alterations in the mode of admitting the water so far remove these risks as to admit of their being again soon opened. The accompanying pamphlet on the subject, describing the cattle drinking trough on which I experimented in India and which, when exhibited in London, secured the highest award, a silver medal, in the Health Exhibition of 1884, and a special certificate at the Congress of the Sanitary Institute of Great Britain in the following year, fully explains the principles I recommend, and which to a certain extent are capable of adaptation to the present public cattle drinking troughs, and would certainly reduce to a minimum the risk now so generally felt, and thus remove the necessity which has culminated in an action the full consequences of which it is difficult to over-estimate.—I am, Sirs, yours truly,

ROBT. PRINGLE, M.D., Brigade-Surgeon.

Blackheath, S.E., Aug. 11th, 1892.

## THE DENTAL PROFESSION.

To the Editors of THE LANCET.

SIRS,—At the last gathering of the British Dental Association, which has just concluded its annual meeting in this city, the following appropriate remarks are reported to have been made by Mr. J. Smith Turner, ex-president: "They now had an Act of Parliament constituting them a legal profession, and they wished to take that position, not because that Act of Parliament was passed, but because they wished to educate themselves in such a manner as to entitle them to that legal position." May I venture to suggest that (1) towards gaining that desired position one of the first steps to be taken by those in authority is to put a stop to the unprofessional practice of advertising in the lay papers. The proof that many of these advertisements are injurious to the dignity of the profession and offensive to the more respectable portion of its members is the fact that they repudiate and strongly condemn them. (2) Now that the dental branch has been recognised and accepted as part and parcel of the medical profession it must conform to the rules and usages of that profession if it would gain the end spoken of by Mr. Turner. Neither physicians nor surgeons are allowed by their Colleges to advertise or do anything to lower the dignity of the profession, and although it is humiliating to witness the expedients practised by some of our own members to make known their disgracefully low charges, they are far exceeded by the trashy advertisements which outrage all professional decency, by setting forth the cheap and other advantages which this or that dentist offers to the public. Our public conveyances even are not free from these objectionable and glaring assertions—in fact we meet with them on every hand.

What would the public think of a physician or a surgeon or a lawyer who advertised that his advice, skill or drugs were the very best that could be had for the money, and if they did not give every satisfaction they would be taken back,

exchanged or money returned? If an enterprising and pushing collector of debts happens to write a letter savouring too much of legal phraseology he is pounced upon and fined; and if a person ventures to style himself doctor, surgeon or apothecary without holding the necessary licence, diploma or degree, he courts the same fate and is justly punished. But, more than that; if either a qualified lawyer or doctor is suspected of an unworthy or unprofessional act he is interviewed by his College, and, if found guilty, forfeits his diploma or licence, which alone gives him the legal right of styling himself doctor or lawyer as the case may be, along with all rights and privileges pertaining thereto. If these laws, then, hold good with the legal and medical professions, surely—now the dentists have obtained an Act constituting them a legal profession—they cannot claim exemption from the pains and penalties which follow any wilful disobedience or infraction of the laws made for their guidance and safe personal conduct as members of that profession. If, therefore, any man without a diploma, or who has forfeited the one he held, styles himself “dentist,” or uses any name, abbreviation or title leading the public to believe him to be a dentist, he ought to be subject to the same prosecution and consequences which affect the lawyer or doctor. Good, honest, sound work needs no puffing, and the public as a rule do not altogether believe in cheapness. If therefore we, as professional men, hold our work and ourselves “cheap,” that is the value at which the public will accept us; and justly so too.

In conclusion I wish to assert that for a member of a legal profession to advertise his name, capabilities or charges is unprofessional, and to advertise himself what he is *not* is illegal. Such men must not be allowed to cast a reflection on the character of the whole body of the profession; and if they cannot intuitively understand the requirements of the profession they must be taught; and if they refuse to learn they must be exorcised from the profession altogether. Advertising “quacks” have been all but stamped out from our particular branch by the strong arm of the law—for where is the man who now dares to call himself physician or surgeon without holding the necessary documents?

I am, Sirs, yours faithfully,

Manchester, Aug. 10th, 1892. HENRY CARTMEL, Surgeon.

## THE NEW LUNACY ACT, 1890.

To the Editors of THE LANCET.

SIRS,—Having lately had some practical experience of this monument of legislative skill, I shall be glad if you will allow me to point out a few of the special beauties thereof. It was lately my duty to receive into my house a young lady whom I found, on visiting her, to be in such a condition as rendered her being placed under certificates—a necessary preliminary of my receiving her. At this time she was under the care of a medical gentleman who occupied the position of “usual medical attendant,” to quote the words of the Act. Now Section 31 of this Act distinctly reads as follows: “One of the medical certificates accompanying a petition for a reception order shall, whenever practicable, be under the hand of the usual medical attendant, if any, of the alleged lunatic.” In accordance with this requirement the gentleman mentioned above signed one of the medical certificates which accompanied the petition to the magistrate. The petition itself was presented by the father of the patient. In course of time the patient was placed under my care, and as in the eye of this law I was no longer a medical man, only a “person having charge of a single patient,” it became necessary that a medical attendant under the Act should be appointed. Naturally the father of the patient was desirous that the usual medical attendant, who was resident in my immediate neighbourhood, should undertake this duty. But I had to point out to both these gentlemen that the fact that the usual medical attendant had signed one of the medical certificates deprived him of the right of any longer acting as such, at least in the sense implied in the Act, and that some third medical man would have to be appointed. This appointment was left in my hands, nothing in the Act in any way preventing its being so if the friends of the patient chose. Thus, Sirs, with the intelligence worthy of Earlswood, our legislators, acting entirely, as was supposed, for the protection of the patient, ordain, and rightly enough, that the usual medical attendant shall sign one of the certificates if practicable, and immediately afterwards say to

him, “Now you have so signed you are no longer trustworthy; you cannot any more be medical attendant; only strangers now can be trusted by us. So that practically all the protection from ill treatment which the presence of the patient’s friend and doctor might bring to bear is carefully eliminated, and had I been a rogue nothing would have been easier than for me and the man whom I had selected to do as we liked with the patient. Her only other protection would have been the Commissioners. But these gentlemen need not visit the patients for twelve months after their reception as lunatics, and when they do so visit them, their apparent object is not so much the wellbeing of the patient as to study in what way the task of the “person in charge” may be made more onerous. In the course of my care of this patient I had one or two more instances of the “ingenuity of stupidity” displayed by the English lunacy law. The patient became much worse, and it became manifest that it was not possible to exert proper control in a private house. Now provision is made in the Act for such an eventuality, another procedure is laid down. A transfer can be effected by the authority of certain persons, among others that of the person who presented the original petition with the consent of the Commissioners.

On the case becoming worse and distinctly urgent, so far as the wellbeing of the patient was concerned, I wired to her father and received in reply his full authority to act as I thought best. I then wired to the Commissioners asking for their immediate consent and stating that I had such authority, also stating the urgency of the case. No reply was received. Time was of high importance. I determined to discharge my patient and have a fresh magisterial order for her reception into a more suitable establishment. To do this I had to find a magistrate. I looked to the Act and found that the persons qualified to act in this capacity in regard to lunatics were “a justice of the peace specially appointed as hereinafter provided, or a judge of the county courts, or a magistrate having respectively a jurisdiction in the place where the lunatic is.” I knew that the justice of the peace who had signed the original order was away from home, and I knew no other justice of the peace in the neighbourhood. I therefore went to the nearest police court. I was civilly received and a list of gentlemen qualified to act as justices of the peace, specially appointed, was handed to me, but I was given to understand that they and they only could act in the matter. I went and called on every one of them and not one was to be found. Meantime my patient’s case was becoming more dangerous and urgent. It was not until late in the evening of the day that one of these gentlemen was kind enough to come to my house, a distance of nearly two miles, and do what was required. The more credit is due to this gentleman as he was not bound to see the patient, and he had just had a long journey. I was able in consequence of his prompt action to transfer my patient the same night.

Next morning I received a note from the Commissioners to the effect that I must have the enclosed form filled up by the patient’s father if her transfer was desired. Of course I could have used an urgency order; but that is a thing to be avoided by all who are acquainted with the Whitehall Board for reasons which need not be recited here. But, Sirs, I think you will agree with me that if justices of the peace are specially appointed and they alone have power to act, as I was informed by the magistrate at the police court, then some arrangement should be made by which they are immediately accessible. Particularly should this be the case in view of the difficulties connected with the urgency order procedure.

Among other improvements of the law which this Act of 1890 was supposed to effect was the protection given to medical men. Let the experience of the late Dr. Carpenter and his partner testify how fallacious this hope has proved. There is absolutely no protection. It is quite true that action may be stayed by application to the High Court, but what protection is this? A medical man may in all honesty sign a certificate, but there is nothing to prevent a scheming attorney from setting the law in motion against him. The very fact of doing so entails considerable expense; counsel must be employed to make the application to the court and other legal expenses incurred even if the application is successful. If, however, it should happen that the judge chooses to think that there is “reasonable ground for alleging want of good faith or reasonable care,” we may find ourselves involved in costly proceedings, which mean not only loss of money—and to most doctors this means ruin—but loss of valuable

time also. The protection afforded by the Act is a figment, and what wonder is there that men decline to have anything to do with such affairs.

I am, Sirs, yours faithfully,  
A GENERAL PRACTITIONER.

Aug. 14th, 1892.

## THE CHOLERA IN PARIS.

(FROM OUR SPECIAL CORRESPONDENT.)

In my previous letters I described the conflict between the rival authorities, the Prefecture of the Seine and the Prefecture of Police. In spite, however, of the confusion this occasions the disinfection of private dwellings is carried out in a scientific and careful manner by these authorities. The same cannot be said of the districts that lie outside their jurisdiction. These are the suburbs beyond the fortifications of Paris, where most of the cases of cholera have occurred. Here the authorities, the mayors and municipalities of the various communes, have been called upon to rigorously disinfect all places where cases of cholera have arisen. In most instances the greatest willingness to carry out this duty has been displayed, but, at the same time, complete ignorance has prevailed as to what ought to be done. At Aubervilliers, where the epidemic has caused so many deaths, the disinfection as at first practised was not only inefficacious, but likely to increase the danger. For the use of this commune there is provided a portable disinfecting stove which is brought to the door of the contaminated house. The bed is taken downstairs and disinfected by steam under pressure. No exception can be taken to this, as it is the most efficacious process known. But precautions should be observed in bringing the infected linen downstairs. I know a case, however, where the bedding was carried down by men deputed for this purpose who had no knowledge whatever of the principles of disinfection. They came to do the work in their ordinary everyday clothes. They freely handled the soiled bedding. After it had been disinfected by exposure to steam under pressure they brought the bedding back to the room. They then proceeded to disinfect the room after having reinfected the bedding by throwing it down on the dirty floor. To disinfect the room they burnt sulphur, but they did not notice that one of the window-panes was broken and that the door fitted so badly that fingers could be passed between the door and the floor. Thus there was a through draught all the time the sulphur was burning. When the operation was over it was possible to enter the room without taking any precautions. The sulphur fumes were not sufficiently strong to cause any inconvenience—they had escaped by the broken window and by numerous apertures. The disinfectors, having concluded their task, without changing clothes or taking any other precautions, went to the nearest wine-shop to refresh themselves. In other cases, when sulphuric acid is not employed, but the room is disinfected by a mercurial solution, complaints have been made that, in the houses of the poor the work is done in a very perfunctory and inefficacious manner. A sort of portable pump should be employed, by which a fine spray of mercurial solution is thrown with considerable and penetrating force on all the furniture, walls, floor, ceiling, corners &c. But instead of doing this the disinfectors have contented themselves with merely wiping over the surfaces with a wet rag. I do not say or wish to infer that such neglect or incompetence is in any wise general. It has existed, nevertheless, much to the surprise and alarm of the newly nominated members of the Permanent Committee of Hygiene, constituted by the Prefect of Police, who inquired on the spot how these things were managed. Of course efforts were at once made to instruct the local authorities and the disinfectors in their employ. The epidemic has now lasted so long that doubtless by this time these lessons have been satisfactorily learnt.

The rag-pickers' quarter at Clichy is, I have already mentioned, about to be pulled down, and from a sanitary point of view this is a most necessary measure. But there are several such quarters in Paris. There is la cité Germain, la cité Dorée, la cité Maupy, la cité Jeanne d'Arc, le Petit-Mazas, le passage Trouillet ou du Soleil, l'île des Singes and la cité Foucault ou la cité de la Femme-en-culotte. The latter place

means, if translated literally into English, the "City of the Woman with the Breaches on." The history of the place is most curious. Mademoiselle Foucault was the cousin of a marshal of France and the daughter of a large manufacturer; but in 1830 her family were ruined. At first, with the assistance of Alexandre Dumas the elder, she obtained some pupils. Finally, however, she had to seek other and manual work, and became a compositor, earning 2 fr. 50 c. per day. But she found that in the next shop men did identically the same work and received 4 fr. a day. Thereupon she dressed herself in trousers, coat and cap, and, a cigarette in her mouth, applied for work in the men's shop. The foreman pretended not to recognise her, and forthwith she earned 4 fr. a day. On this she saved money; and having discovered that huts for rag-pickers did not cost much to build, but brought in good rents, built the rag-pickers' quarter in Clichy, now known as la cité Foucault, or la cité de la Femme-en-culotte. When Mdlle. Foucault died, she left this property to the municipality of Clichy, which had been the witness of her misery and of her fortune. The structures, such as they stand, are now estimated at only £600, yet they bring in rents to the amount of £480 per annum. They are principally inhabited by rag-pickers, but they also house some street musicians, men who dance on eggs, swallow swords, castrate dogs and cats, and follow other bohemian occupations of this description.

It is a rectangular place, or narrow street, with a long house two stories high on each side, and containing about thirty single-room tenements on each floor. Each room has a door, which serves the double purpose of door and window, and each room is a little larger than an ordinary prison cell. The furniture very often consists of old rags, and a broken chair and table, but there is almost invariably a stove. Very often straw, picked up in the street when there are removals of furniture, constitutes the bedding. On this straw the rag-picker, his wife, his children and his dog, all sleep together. They are content, for they only pay 1s. 3d. to 2s. a week for this lodging, and are free to be as dirty as they please. The rag-picker sleeps when he returns from work—that is, at the dawn of day. By that time he has walked a very long distance; he is thoroughly exhausted, so he poises his great basket, full of the rubbish he has picked up, against the wall and, without attempting to take off his clothes, drops on the straw to sleep. When he has rested he empties his basket on the floor of his room, and sorts the rags from the paper, subdivides the rags in four piles—those of wool, cotton, linen, and silk. Each of these piles are divided into the clean rags and the dirty rags. The same has to be done for the paper—the clean from the dirty, the white from the coloured paper. Then the bones are separated from the glass; the tin, the old shoes, the bits of iron &c. all form different heaps. Out of all this he also selects remnants of food—the head of a chicken, leaves of cabbage, crusts of bread, bones that have still some meat adhering. All this he scrapes with a knife and washes carefully, and then it all goes to make the national "pot-au-feu," or soup, which is the Frenchman's delight.

There are a great number of rag-pickers who are known and kindly treated by domestic servants. They then receive direct from these domestics what would otherwise have been thrown out into the streets, and sometimes more than this is given to them. Thus they return to their quarters with a very strange mixture of leavings from rich men's tables. On this they make good meals. One rag-picker once remarked that the only difference between his class and rich people was that they had their food mixed before eating it, whereas the rich mixed their food after eating it. Needless to remark that men and women living in such a manner are very likely to contract and to convey disease.

## NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

*Tyne Port Sanitary Authority,*

At a late meeting of the Tyne Port Sanitary Authority the matter of the medical officer's salary came up for discussion. Dr. Armstrong asked for an augmentation owing to the great increase in his work. At present he has only £80, with an allowance of £20 for an assistant at South Shields. The chairman, in reference to the increase in Dr. Armstrong's

work, mentioned the magnificent improvements which had taken place of late years in the sanitary arrangements of vessels, the water-supply, and the state of the forecastles &c., which, he thought, justified an increase in Dr. Armstrong's salary. Liverpool paid £100 to its medical officer, and there were only half the visits paid to vessels in the Mersey that were paid in the Tyne. It was explained that although the vessels entering the Mersey were larger those entering the Tyne were twice as numerous. The salary question was deferred to a future meeting.

#### *Ingham Infirmary, South Shields.*

The annual meeting of the governors of the Ingham Infirmary, South Shields, has been held and the report showed that the total number of patients who received treatment was 6,156, while the total income was about £1,800 and the expenditure about £100 less. The decrease in income was not considered serious, taking into account the great disputes between capital and labour during the past year leading to depression in the trade of the district. The working men's subscriptions showed a decrease of nearly £100.

The Newcastle Town Moor management have decided to plant a belt of trees thirty feet wide which will practically surround this fine expanse of open ground, proving at once useful and ornamental, for the truth must be told that for most of the year the moor is rather bleak owing to its northern exposure. It is to be hoped that the plantations will give the necessary shelter. It is estimated to cost from £7000 to £8000.

#### *Scarborough.*

Scarborough has just made the appointment of a medical officer of health, and out of forty-one applicants the post fell to Mr. G. H. Monk of Shrewsbury, who will have to devote his whole time to the duties of the office which include those of surgeon to the police, borough analyst, meteorologist and medical attendant to the fever hospital. The salary is only £325 per annum for all this. "The Queen of Yorkshire watering-places" might well have been a little more liberal in this matter.

#### *Serious Accident to Dr. Cook of Gateshead.*

It was reported here last week that Dr. Cook of Gateshead had met with a serious accident while touring in Norway. A passenger who arrived in Newcastle on Friday last has supplied the following particulars. Dr. Cook with two friends who had been on the Hardanger Fjord had been driving in one of the cars of the country from Lattefos to Odde on the return journey. All went well until they came near the latter village, when the horse shied at the sight of the white umbrella of an artist sketching on the road; the conveyance, swerving against one of the boulders which mark the course of the road, was overturned and fell upon the passengers, who were held fast beneath the vehicle. One of Dr. Cook's fellow-passengers was considerably bruised about the face, but escaped with this and a severe shock; but it was unfortunately otherwise with Dr. Cook, upon whom the greater force of the upset seemed to fall. It was found he had three ribs fractured, one of them in two places, and he was otherwise considerably bruised and shaken by the collision. As soon as possible Dr. Cook was carefully removed to Bergen; he has been placed in a private hospital, where he is receiving every surgical care and is reported to be doing as well as could be expected. This last news has given satisfaction to his numerous professional friends here. Dr. Cook is, I believe, one of the oldest medical officers in the Volunteer service.

#### *Cumberland.*

The Keswick Cottage Hospital, built for the Monk-Hall estate, adjoining the beautiful Fitz-park (so well known to visitors to the lake district), by Mr. Henry Hewitson, is to be opened on Friday next by Lady Jane Spedding of Mirehouse.

#### *A Cumberland Lady's Charitable Bequests.*

The will of Mrs. Jane Dover of Skiddaw Bank near Keswick has lately been proved. Amongst various bequests she leaves £3000 Two-and-three-quarter per cent. Consols to the Royal Society for the Prevention of Cruelty to Animals, £1000 to the Liverpool Branch of the said society; also £500 each to the Scottish Society for the Prevention of Cruelty to Animals, the Liverpool Temporary Home for Lost and Starving Dogs, the Royal Albert Asylum for Idiots and Imbeciles at Lancaster, all free of legacy duty. The residue of her estate she directs to be divided in equal shares amongst various religious societies and the institutions

above mentioned, so that the dogs are well provided for by this kind lady. The net value of her estate in England was proved at over £12,000.

The committee of the Darlington Cyclists' Parade have announced that they will distribute the net proceeds, amounting to about £56, amongst the Darlington Hospital and other local charities.

Newcastle-upon-Tyne, Aug. 17th.

## SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

#### *Epidemic of Scarlet Fever in Glasgow.*

THE supplementary hospital for epidemic diseases in Parliamentary-road had to be opened recently on account of a smart outbreak of scarlet fever in one of the southern divisions of the city, which had been traced quite clearly to a particular dairy and a particular farm. This epidemic was of a novel kind, at least in Scotland, inasmuch as it arose not in connexion with preceding human disease in the dairy in question or in the farm, but apparently from disease of some kind on the teats of the cows, not easily distinguishable from cow-pox. The Health Committee of the Town Council, aided by the Renfrewshire authorities are making a rigid inquiry into all the circumstances; they intend also to ask the assistance of the Local Government Board of England, as they are understood to be familiar with inquiries of this particular kind. Meantime it is satisfactory to note that the epidemic, except for possible secondary cases, is at an end, the dairyman and the owner of the farm concerned having given every assistance to the sanitary authorities in checking its spread.

#### *Edinburgh University.*

The University authorities have received intimation of the approval by the Queen in Council of Ordinance No. 16 of the Universities Commission (Edinburgh No. 1—Regulations for Degrees in Medicine). The provisions of the Ordinance will come into operation at the beginning of the ensuing winter session.

#### *Medical Education of Women in Glasgow.*

The experiment made by the directors of the Royal Infirmary in opening certain of their wards for the clinical teaching of women has turned out a failure, and the governing authorities of the infirmary and also those of St. Mungo's College have now determined to exclude females both from the wards and from the college classes. It is about two years since the students of Queen Margaret College were granted facilities for obtaining clinical and pathological instruction in the infirmary, and at the same time the ladies attending medical classes in St. Mungo's College and other lady "medicals" were afforded the same opportunities, the Queen Margaret students, however, having their instruction separately, while the others attended mixed classes both in college and in the wards. The arrangement, however, has come to grief over the dispensary question, it having been found inconvenient, if not impossible, to carry on the very essential dispensary work of the curriculum either in mixed classes or separately, the objection to mixed dispensary classes having come, not from the women, but from the male students. To get over this deadlock the managers have decided to exclude ladies at once from St. Mungo's College and from the wards, the only exception made being in favour of Queen Margaret students, who will be permitted to attend pathological and clinical classes till the end of the summer session of 1893. All this comes as something of a shock to the friends of medical education for women in Glasgow, as unless some new arrangement is speedily made such teaching must come to an end in this city. Queen Margaret College in particular will be in a difficulty and will specially feel the hardship; it has been prospering to the satisfaction of its friends, and has only recently been affiliated to Glasgow University, which has taken over its buildings and endowments and with them all duties and responsibilities. Amongst other things it must provide clinical facilities for its lady medical students, and at first sight it is not easy to say where these are to be found. The Royal Infirmary is shut to ladies and the Western Infirmary, already much overcrowded with male students, refused some time ago to make room for ladies, and

it is not likely that recent events will make it more ready to admit them. Two ways out of the difficulty offer themselves. The enormous amount of clinical material, hitherto practically unused, to be found in the Town's Hospital, the large pauper hospital of Glasgow, might be made available. But a much better field for study would be found in the Victoria Infirmary, opened about two years and a half ago, and situated in one of the prettiest parts of the environs of Glasgow. The Victoria Infirmary is fully equipped as an institution suitable for medical education, having an ample number of beds and a newly inaugurated out-door department in which all forms of practical training could be carried on. Further, so far, it is not connected with any medical school, and this opens a field for clinical instruction free and uncomplicated by the presence of male students. If the governors of the Victoria Infirmary are willing to admit them, lady students will have in their wards opportunities for clinical study unrivalled in Scotland. One obstacle suggests itself, the great distance which intervenes between Queen Margaret College and the Victoria Infirmary, the former being in the extreme west of Glasgow, the latter in the extreme south. This obstacle would really be a fatal one were it not that there lies at hand a ready means of obviating it. A few years ago Dr. Muirhead of Cambuslang left a sum of about £40,000 (no mean legacy) for the erection and endowment of a medical school for women on the south side of Glasgow and near the Victoria Infirmary. So far this sum has not been applied to the purpose for which it was left by its donor. Queen Margaret College, however, notwithstanding the very specific direction given by Dr. Muirhead as to the exact locality of the new school, has made persistent efforts to obtain possession of it. And to some extent its action is justified, as it would be nothing short of a misfortune were two medical schools for women to be opened in Glasgow. An attempt at competition would probably lead to the failure of both. But the way of escape from difficulty is easy. Queen Margaret College, with its affiliation now completed and its £15,000 of endowment, should join hands with the Muirhead trustees, and send their entire medical faculty to the south side of the river, keeping their arts and literature classes in their western buildings as at present. With their conjoined funds they could build and endow a suitable school near the Victoria Infirmary, where the theoretical and practical portions of medical training could easily and satisfactorily be undertaken. If this were done, and suitable terms made with the governors of the Victoria Infirmary, Glasgow would possess a medical school for women second to none in this country. The university authorities would be well advised if they considered carefully such a plan as that sketched here, otherwise they will have some difficulty in providing the indispensable hospital facilities for their newly acquired members, the lady medical students.

Aug. 17th.

## IRELAND.

(FROM OUR OWN CORRESPONDENT.)

### *City of Dublin Hospital.*

THIS institution having proved inadequate to accommodate the numerous applicants, the board have determined to erect a structure which will about double the present accommodation. An excellent design has been selected and estimates made showing that a hospital according to the plans adopted may be constructed at a cost of from £9000 to £10,000. Lord Pembroke has promised £6000, and the subscriptions up to June last were close on £2000, so that the board look forward with confidence to the amount still required being obtained at no distant date.

### *The late Samuel Chaplin, J.P., F.R.C.S.I., of Kildare.*

It is proposed to erect a memorial window in Kildare Cathedral to the memory of the late Mr. Chaplin as a mark of esteem, he having been mainly instrumental in raising a sum of £7000 for the restoration of the cathedral. The cost of the memorial window will be £250, towards which about £150 has already been subscribed.

### *Death of Mr. Denis D. Redmond, F.R.C.S.I.*

Mr. Redmond died last week after a short illness. He was ophthalmic and aural surgeon to St. Vincent's Hospital,

assistant surgeon to the National Eye Infirmary, an examiner in the Royal University and a member of the Royal Dublin Society.

### *National Hospital for Consumption for Ireland.*

The total collected up to date to erect an institution for the treatment of phthisical patients is £10,231 19s. 1d. As, however, it is contemplated to have a hospital capable of accommodating 100 patients almost as much again may reasonably be expected to be required. Among those who have contributed liberally may be named Lord Iveagh, who has given £1000; Mr. T. P. Cairnes, £1000; Earl Fitzwilliam and Mr. Mitchell Henry of Galway, £500 each, while a considerable number of gentlemen have given £100 each. It is gratifying to state that at last a suitable site has been settled on for erecting the hospital—a place which no one can cavil at and which has been unanimously approved of by the medical men on the committee of management. The situation of the new hospital is in the county Wicklow, between Newcastle and Newtown Mount Kennedy, on a dry soil, well sheltered from adverse winds. Earl Fitzwilliam, who is the principal owner of property in this county—the most beautiful in Ireland—has very generously presented a site of nearly twenty acres, and this selection of a site will undoubtedly have a large influence on the donations, as a large number have abstained from contributing until the locality for the proposed hospital had been agreed upon. I see no reason to doubt that before the year closes a sum of £20,000 will be obtained for an institution with so many claims for support on the charitable.

### *Sir Francis Xavier MacCabe.*

On Saturday His Excellency conferred the honour of knighthood on Mr. MacCabe, Medical Commissioner Local Government Board. Sir Francis MacCabe's services in various departments—in Irish Prisons and Reformatory Schools, as Inspector and afterwards Medical Commissioner Local Government Board—have been of immense value to the community. He is a thoroughly competent official, and the distinction conferred upon him has been well earned by good and faithful service.

### *British Institute of Public Health.*

The first meeting of the Hygienic Congress will take place to-morrow (Wednesday) at the College of Surgeons, when the President, Sir Charles Cameron, will deliver an address, and afterwards a discussion will take place on the causation of typhoid fever. On the following day the subject of Compulsory Notification of Infectious Diseases will be discussed, and Sir C. Cameron will exhibit carbonic acid snow and point out its antiseptic properties.

### *Death from Arsenical Poisoning.*

A lady died at Ballintemple, county Cork, last week from a poisonous dose of arsenic. The deceased had made more than one previous attempt on her life. She appeared to suffer no pain, and was unconscious for two days before death; but the strange absence of certain definite symptoms in some cases of poisoning by arsenic are not altogether uncommon, and exceptions and anomalies of the most perplexing kind are occasionally manifested.

### *Cork City Hospitals.*

The generous donation—£1000—of Sir J. Arnott has been distributed among the following hospitals—viz., South Infirmary, £250; North Infirmary, £200; Fever Hospital, £150; Mercy Hospital and Women and Children's Hospital, £100 each; Blind Asylum, £75; Lying-in Hospital, £50, and some other institutions £25 each.—At the monthly meeting of the governors of the South Infirmary last week Dr. A. W. Sandford was appointed ophthalmic surgeon to the hospital, and a vote of thanks was accorded to Mr. Corbett, surgeon dentist, who had resigned, for services for many years to the hospital.

Mr. Hengler, the well-known circus proprietor, has promised to distribute the receipts of one evening performance this week among the City medical charities.

Mr. Albert Croly, F.R.C.S.I., of Greenfield, Rathfarnham, county Dublin, has been placed on the commission of the peace for the county Dublin.

On the 25th inst. the governors of the Richmond Hospital will elect an assistant-surgeon to hold office for three years. There is no salary attached to the post.

August 16th.

## PARIS.

(FROM OUR OWN CORRESPONDENT.)

*Laborde's New Method of producing Artificial Respiration.*

To the methods of resuscitation in suspended animation associated with the names of Marshall Hall, Silvester and Howard there must now be added yet another invented by Dr. Laborde, who presides over the physiological laboratory of the Paris faculty. The value of the new method is enhanced by its extreme simplicity and facility of application. It consists in drawing the tongue well out of the previously opened mouth and then imparting to that organ energetic and rhythmic backward and forward movements. This manœuvre has the effect of stimulating the respiratory reflex through the traction on the tongue and the excitation of its basal portion. The idea of applying this method to the human being was suggested to Dr. Laborde by its success in the laboratory. In cases of suspended animation in animals under experiment—whether due to syncope, accidental asphyxia, or to chloroform or chloral—Dr. Laborde has long been in the habit of supplementing electrification (the passage of interrupted currents from the mouth to the anus) and ordinary artificial respiration with this method of rhythmic tongue-traction, which of itself was often sufficient to determine respiratory movements after a series of loud hiccoughs, which at first passive—*i.e.*, provoked by the manœuvre only—soon became spontaneous. Dr. Laborde cites (*Académie de Médecine*, July 5th) the case of two individuals whose lives he saved by his method. The *modus operandi* is very simple. A spoon, the handle of a knife, or any such instrument is utilised for the double purpose of keeping the jaws apart and pressing on the base of the tongue. The tongue is then seized between the finger and thumb—which, to avoid slipping, are enveloped in a handkerchief—and pulled forcibly forwards out of the mouth. The organ is then subjected to the rhythmic to-and-fro movements, eighteen to the minute, until success crowns the operator's efforts. Whilst advising recourse to the methods usually employed, Dr. Laborde believes that his own proceeding is the most effectual, and that it will often succeed even when all hope is apparently fled.

*Dr. Brouardel on "Submersion."*

In connexion with the above readers of THE LANCET will be interested by some remarks of Dr. Brouardel:—"In deaths from submersion three mechanisms may come into play. The fatal result may ensue suddenly, at the very instant of the plunge. Here instantaneous inhibition of the respiratory, and perhaps also of the cardiac, centres occurs, probably through reflex action exerted by the cold, the principal afferent nerves being the superior laryngeal. In such a case the individual expires without a drop of water having entered the trachea. In another class of cases death may not be due to reflex inhibition at all. The submerged one may be unable to rise to the surface, being entangled at the bottom of the river by boulders or weeds. Experiments on animals show that here nothing penetrates into the respiratory tree during the first minute, the glottidean sphincter being in a state of spasm. But this spasmodic state is soon succeeded by relaxation and water then enters freely. A dog weighing five kilogrammes has been known to absorb thus in one minute no less than 400 grammes of liquid. In both the foregoing classes of cases artificial respiration either by the Silvester or the Laborde methods, together with, in the latter instance, evacuation of the water aspirated into the lungs, may suffice to save the individual. Unfortunately, the third and much more frequent mechanism by which fatal drowning may occur is much more dangerous in its effects, and the means at our disposal are too often inadequate to avert the consequences. Here, the drowning man, before he is finally engulfed, struggles and reappears once or twice at the surface. His efforts at respiration introduce into his lungs not only water largely mixed with air, but also the contents of the stomach expelled from that organ by the violent contractions of the diaphragm. In addition there enters into the circulatory system a quantity of water equal to the fourth or even the third of the volume of blood, a fact easily proved by examination of the blood with the hæmocytometer. Then, again, the presence of water in the ultimate alveoli causes the prompt exfoliation of

the pavement epithelium with which they are lined, a circumstance which damages their respiratory functions. We have thus three conditions which render the chances of recovery problematical—*viz.*, the obliteration of the bronchial tree by water, the hæmremia, and the spoilt state of the alveoli."

*A Venerable Student.*

Fifty-nine years is a long time to wait before emerging out of the pupil stage and beginning the practice of medicine. Such a feat has, however, just been accomplished by M. Vouillemin, mayor of his native town, Bourmont, member of the board of health of his department, the Haute-Marne, and pharmacien de première classe. Fired with the praiseworthy ambition of rising in the professional and perhaps social scale, the worthy mayor applied himself to the assiduous study of his new art at the Nancy Faculty, where he went through the examination mill like his beardless comrades, and the other day crowned his work by triumphantly passing his thesis for the doctorate. The final ordeal over Monsieur le Maire was presented by the youngest of the first year's men with a bouquet, on the ribbon ornamenting which was borne the following device:—"Au doyen des étudiants ses camarades de la Faculté de Nancy."

Paris, Aug. 17th.

## VIENNA.

(FROM OUR OWN CORRESPONDENT.)

*The Action of Nuclein.*

To the number of the lymphagoga—now better known on account of the experiments of Heidenhain, Roemer and Goertner—a new substance has been added by the recent researches of Professor Horbaszewski of Prague. In the course of his researches on the origin of uric acid in the mammals he made the interesting discovery that leucocytosis was increased in the animals by the injection of nuclein. Further experiments proved that nuclein could be administered in man in doses of from five to ten grammes without producing any evil effects. It has now been proved by recent experiments that inflammatory processes going on in the organism are considerably augmented by the injection of nuclein. In cases of lupus, local and general reaction (rising of temperature up to 39.90 C.) was produced by the internal administration of a half to three grammes of nuclein per diem. The symptoms of reaction remained as long as the nuclein was used and disappeared when the administration of the nuclein was withdrawn. It must be remarked that the same reaction could be obtained again by using the same dose of nuclein as before, while it is necessary to increase the dose of tuberculin, as is well known, in the course of treatment. It was also found that torpid varicose ulcers of the leg healed quickly under the internal use of one to two grammes of nuclein per diem. In cases of carcinoma and of large abscesses the administration of nuclein did not produce any effect, while in syphilitic ulcers granulation could be observed to occur. The effect of nuclein has been most marked in cases of skin affections, but the general reaction only occurred in cases of lupus, perhaps on account of the resorption of the tuberculous matter which is present in the lupous growths. The nuclein used by Professor Horbaszewski was prepared from the pulp of the spleen of calves which had been subjected to digestion by pepsin and hydrochloric acid and subsequent deputation.

*Surgery of the Brain in Epilepsy.*

According to a communication received recently, in the case of one of the two epileptic patients who were operated on by Professor Benedict this year the epileptic fits returned again after cessation for a few months. The microscopical examination of the extirpated parts of the cortex did not reveal any pathological condition. It seems that this surgical method of treatment of epilepsy requires prolonged observation of the patients after the operation before its value can be sufficiently estimated.

*Cholera and Infectious Diseases.*

Up till now no cases of cholera have occurred in Austria-Hungary, and the rates of prevalence and mortality of the other infectious diseases are not higher than in previous years at the same season. Sanitary examinations are now

carefully made throughout the whole empire and sometimes reveal gross nuisances which would otherwise have escaped public attention.

Vienna, Aug. 15th.

## Obituary.

DENIS D. REDMOND, F.R.C.S.I.

A WELL-KNOWN Dublin practitioner died on the 11th inst., after a short illness. He pursued his medical studies at the schools of Dublin, London, Paris and Vienna, and then commenced practice in his native city. He quickly made his way, and at the time of his death enjoyed an unusually large measure of success as an ophthalmic and aural surgeon. Mr. Redmond possessed a most complete knowledge of physical science which helped him in no inconsiderable degree to reach the high position he undoubtedly held. He occupied many public positions, being ophthalmic and aural surgeon to St. Vincent Hospital, examiner at the Royal University, lecturer on ophthalmology at the Catholic University, assistant surgeon to the National Eye and Ear Infirmary and member of the Council of the Ophthalmic Society, &c.

## MEDICAL TRIAL.

### MEDICAL MEN AND THE NEW PUBLIC HEALTH ACT.

DR. RAYNER D. BATTEN of Notting-hill-square, Campden Hill, appeared at the West London Police-court on Friday to answer a summons for having on July 29th attended, at the Queen's Jubilee Hospital, Earl's Court, a patient named John Weston, aged fifteen years, of 30, Dymock street, Fulham, who was suffering from diphtheria, without sending a notice or certificate to the medical officer of health as required by the Public Health (London) Act, 1891. The summons was issued on the application of Mr. Cooney, the medical officer of health for Fulham, and Mr. Blanco White appeared in support of it. Mr. A. O. Scott was for the defence.

Eliza Weston, of 32, Wandsworth Bridge-road, Fulham, said that on July 28th she took her son to the Jubilee Hospital. She took the child again on the 29th and saw defendant, who told her that the child was suffering from diphtheria and would have to go away. She consented to his being sent away.

Mr. Cooney was called and said that he had not received any notice from the defendant that he had attended the child in question and that it was suffering from diphtheria.

Mr. Scott: From whom did you receive this notice?—Witness: I have not received any legal notice.

Who gave you the information?—The last witness and I received notice on Aug. 2nd from the Asylums Board that a child had been received suffering from diphtheria and that the child came from the Jubilee Hospital.

Mr. Blanco White: I believe that in consequence of this notice not having been received there was a delay of five days in disinfecting the premises and during that time serious consequences might have arisen.

Mr. Cooney: That is so, but not only that. I have not yet been able to send in the papers which I am obliged to do and I cannot obey several sections of this Act.

Mr. Scott, for the defence, said that Dr. Batten was one of the medical gentlemen attending the Jubilee Hospital without any reward of any kind, and in the course of his attendance there saw a large number of patients. He first saw the child in question on July 29th, and in his opinion the case was not very serious, but still it was a case of diphtheria. He told the mother that it would have to go away, and without waiting at once filled up the proper notice to be sent to the medical officer. Dr. Batten handed the notice to the secretary of the hospital and told him to do what was necessary.

Mr. Curtis Bennett: The Act of Parliament says nothing about instructing someone else to do it. The words are "he shall forthwith send."

Mr. Scott submitted that Dr. Batten had, in fact, sent within the meaning of the words of the section the notice to the medical officer. Instead of sending it himself he had handed it to the secretary of the hospital to do so.

Mr. Curtis Bennett: It is for the medical practitioner to send it himself, not to give it to someone else and ask him to send it.

Mr. Scott: Handing the notice to the secretary of the hospital is sending.

Mr. Curtis Bennett: No, it is not. To give the notice to a person who is not under compulsion to send it is no more sending it than if you gave it to someone else in the street.

Mr. Alfred J. Schneidan, the secretary of the Jubilee Hospital, was called and said the notice was handed to him by Dr. Batten with the request that he would send it on at once.

Mr. Curtis Bennett: To whom?

Mr. Schneidan: To the medical officer, I suppose. I called up the telephone to the Metropolitan Asylums Board and asked if I should send the certificate as usual and they said, "Hand it to the nurse."

Mr. Curtis Bennett: They meant that you should hand to her the certificate for the patient's admission to the hospital, not the notification to the medical officer of health.

Mr. Schneidan said that he handed it to the nurse, believing that he was acting rightly.

Mr. Scott submitted that, although the secretary to the hospital had made a mistake, the defendant had done his duty in regard to sending the notice.

Mr. Curtis Bennett: You must show me, then, that the doctors of the Jubilee Hospital are exempted from the requirements put upon all other medical practitioners.

Dr. Batten was called as a witness in his own defence and corroborated the statement made by Mr. Scott on his behalf. He said that at the time this certificate was filled up some twenty-five patients were waiting for his attention to them.

Mr. Curtis Bennett said it was quite clear that the defendant, without intentionally going round the Act of Parliament, had not done what was required of him. Had it been the case that the defendant had wilfully flown in the face the full penalty of a forty-shilling fine and costs would have been imposed. No doubt the authorities at the Jubilee Hospital, now that what was required of them by the Act had been pointed out, would see that in future it was complied with. Under the circumstances only a modified penalty of a fine of 10s., with 12s. costs, would be inflicted.

## Medical News.

ST. JOHN AMBULANCE ASSOCIATION.—H.R.H. Princess Beatrice, who has recently obtained the first aid certificate of the St. John Ambulance Association, has consented to become the president of a new Deeside centre, to include Balmoral, Crathie and neighbouring places.

THE SEAMEN'S HOSPITAL.—As a result of the privilege accorded by the directors of the Peninsular and Oriental Steam Navigation Company of throwing open to the public their magnificent vessel the *Himalaya* the funds of the Seamen's Hospital have benefited to the extent of £120.

A SICK HOSPITAL FOR THE LUNATIC ASYLUM, INVERNESS.—The Inverness District Board of Lunacy has resolved to erect a sick hospital in connexion with the asylum, to accommodate about 150 patients, on the plan of the hospital lately erected at Montrose. This scheme is adopted to relieve the overcrowded state of the institution.

DRAINAGE WORKS (WEYBRIDGE DISTRICT).—The Chertsey Sanitary Authority has purchased twenty-eight acres of land, at a cost of £6000, for the drainage of the Weybridge district, on a site in the valley of the river Wey. The system to be adopted will be chemical precipitation and filtration through land.

OUTBREAK OF GLANDERS AT BEDDINGTON.—The Croydon Rural Sanitary Authority has reported a serious outbreak of farcy and glanders on the Corporation Sewage Farm at Beddington, where seventy or eighty horses belonging to various owners are located for grazing purposes. The local veterinary inspector detected two serious cases of glanders, and the animals were shot and buried.

SOCIETY OF APOTHECARIES OF LONDON.—At the recent Examinations for the prizes given annually by the Society of Apothecaries the successful candidates were as follows:—*Dobsony*: 1st, Edward Guy Dru Drury, student of St. Bartholomew's Hospital, a Gold Medal; 2nd, Stanley Bean Atkinson, student of St. Bartholomew's Hospital, a Silver Medal and a Book. *Materia Medica and Pharmacy*: 1st, Richard Henry Norman, student of Westminster Hospital, a Gold Medal; 2nd, William Douglas Knocker, student of St. Thomas's Hospital, a Silver Medal.

MEDICAL MAGISTRATES.—Mr. William Wright Hardwicke, M.R.C.P. Edin. &c. and Mr. Samuel Evans, L.R.C.P. Lond., M.R.C.S., have been placed on the Commission of the Peace for the Borough of Harwich.—Mr. Charles W. Browne, M.R.C.S., L.S.A., of Bushman's Kop, Orange Free State, has been appointed a justice of the peace for the districts of Rousville and Wepener. His Excellency the Lord-Lieutenant has assigned Her Majesty's Commission of the Peace for the Borough of Dublin to Mr. G. F. Blake, Registrar of the Royal College of Surgeons in Ireland.—Mr. John Keys, L.R.C.P., of Whitehall House, Dublin, has been placed on the Commission of the Peace for the Borough of Dublin.—Mr. William Mitchell Banks, M.D. Edin., F.R.C.S. Eng., has been placed on the Commission of the Peace for the city of Liverpool.

**SMALL-POX AT LEEDS.**—Considerable alarm prevails at the continued extension of the outbreak of small-pox at Leeds. The number of patients is gradually increasing.

**SUPERANNUATION GRANT.**—Dr. G. R. Barnes, medical officer of the Ewell sanitary district of the Epsom Union, has been granted by the Epsom Board of Guardians a superannuation allowance of £35 per annum, and, pending the sanction of the central authority a further sum of £15.

**THE JUBILEE NURSES' ASSOCIATION.**—At a meeting of the Brechin branch of this Association on the 10th inst. a letter was read from Mr. Robert Duke of Bareshill offering a donation of £500 to the funds of the branch from his sister, Miss Duke of Eskpark, and a similar donation from himself. Mr. Duke further intimated that Miss Duke and himself intended subscribing £10 annually to the branch.

**THE NORTH WALES MEDICAL ASSOCIATION.**—The annual meeting of this Association was held at Barmouth on the 10th inst., and the usual elections were proceeded with. Dr. John Roberts, J.P., was chosen as president for the ensuing year, Mr. S. Griffith was re-elected treasurer, and Dr. Jones-Morris hon. secretary. After the reading of papers the members of the Society dined together.

**LLOYD COTTAGE HOSPITAL.**—The useful work carried out during the year at Bridlington in connexion with its cottage hospital was recounted in the report read at the annual meeting of its friends and supporters last week. In-patients to the number of 109 have benefited during the past year by the resources of the hospital, whilst 110 out-patients received medical and surgical treatment at the hands of the physicians and surgeons attached to the institution.

**A NEW PARK FOR TOTTENHAM.**—The grounds attached to an historic building at Tottenham, known as Bruce Castle, have recently been purchased by the Tottenham Local Board of Health, and on the 13th inst. they were formally thrown open to the public. Addresses were afterwards delivered from a temporary platform in the park by Mr. Howard, M.P., and others. Later on there was a display of fireworks.

**TESTIMONIAL.**—Last week the friends and patients of Dr. George Wilson of Huntly assembled at a banquet, under the presidency of the mayor, to do honour to their fellow-townsmen, who for sixty years had carried on medical practice in Huntly, and who has signified his intention of retiring from the cares and anxieties of professional life. On the occasion in question an address, followed by 450 signatures, was presented to Dr. Wilson, accompanied by a silver tea service and a portrait in oil of their venerable guest.

**MANCHESTER AND SALFORD LOCK HOSPITAL.**—A general meeting of the trustees and friends of the Manchester and Salford Lock Hospital was held on the 11th inst. The committee, in their report, spoke of the result of two years' steady work, in which the number of cases treated had been larger than usual. In 1890 the death of Dr. Alfred Blackmore removed an honoured name from the staff, and left a vacancy which the committee filled by the appointment of Mr. Alexander Wilson, F.R.C.S. Eng. The report was adopted, together with a statement of accounts showing a balance on the right side.

**LANCASHIRE ASYLUM BOARD.**—A meeting of the Lancashire Asylum Board was held recently at the County Offices, Preston, and the Rev. C. T. Royds, who presided, presented the report of the Subcommittee on Additional Asylum Accommodation. There were, he said, three sites brought before the committee as combining all the requisites desirable for the proposed new asylum, either of which, he thought, would meet the approval of the Lunacy Commissioners. The first site was Duxbury Hall, near Chorley, containing 512 acres; the second was Penwortham Priory, 147½ acres; and the third was Winwick Hall, near Warrington, with an area of 130 acres. It was resolved that the committee ascertain and report the best terms on which the Duxbury Hall site could be obtained; and a similar resolution was adopted with regard to the Winwick estate. It was agreed that £700 be granted from the asylum fund for additional accommodation at Prestwich Asylum; and £5500 for a similar purpose at Rainhill Asylum.

It is officially announced that the Queen has nominated Professor Sir George H. B. Macleod, M.D., Surgeon in Ordinary to the Queen in Scotland, to be, for five years from the 15th of September, 1892, a member of the General Council of Medical Education and Registration of the United Kingdom for Scotland.

**PRESENTATION.**—Dr. M. T. Mackenzie of Scolpaig House, North Uist Inverness, where he has been the parochial medical officer for the past seven years, was last week the recipient from the inhabitants of the island of a testimonial consisting of a handsome Stanhope gig and a set of silver-mounted harness.

**RETREAT FOR INEBRIATES.**—The twelfth report of the Inspector of Retreats under the Inebriates Acts 1879 and 1888 for 1891 deals with seven retreats licensed by local authorities during the past year. The licences of all the establishments existing in the foregoing twelve months were received with one exception, and a licence was granted to a new retreat for female patients at Westgate. The general condition of the establishments was described as satisfactory. In 1890 the number of the inmates was 109, and last year there had been an increase over that figure of six.

**POLLUTION OF THE AIRE.**—On the 10th inst. representatives of the various local authorities of Yorkshire met at Keighley, by invitation of the mayor, to confer on the best means of effecting an improvement in the river Aire, which had been gradually exhibiting signs of increasing pollution. The testimony of several of the speakers pointed clearly to trade refuse as the chief source of that pollution, and in the end a motion was agreed to that the Sanitary Committee of the West Riding County Council be asked to employ a chemical expert who should advise local authorities as to the best way of treating trade effluents.

**DEATH DURING THE ADMINISTRATION OF CHLOROFORM.**—An inquest was held at the Town Hall of Portsmouth on the 15th inst. respecting the death of a girl aged thirteen years who died whilst being prepared for an operation for the removal of a nevus on the back. Three medical practitioners attended at the parents' house for the purpose of proceeding with the operation, but, according to the report of the evidence given at the inquest, during the process of administering the anæsthetic the respiration of the patient became embarrassed and the pulse failed. Sustained efforts to restore animation were found to be ineffectual. The jury returned a verdict of accidental death.

**NEW INFIRMARY, SOUTHPORT.**—Very satisfactory progress has been made towards the proposed scheme for erecting a new infirmary at Southport. The necessary plans for the building have been adopted, and although the committee at first decided to limit the cost of it (exclusive of furnishing) to £12,000, the expenditure will considerably exceed that sum. The beneficiaries of the Scarisbrick Estate have given the site on Scarisbrick New-road, and the promises of donations and subscriptions now amount to £15,400. The mayor (Alderman G. A. Pilkington, M.R.C.S.), the chief originator of the scheme gave at once £1000 and asked for nine other contributions of a similar sum. So far eight have been forthcoming towards the building and endowment funds respectively.

## MEDICAL NOTES IN PARLIAMENT.

THE short session of Parliament was brought to a close this week. The House of Lords met on Monday, when Lord Salisbury formally intimated that he had resigned office. Both Houses met on Thursday. In the Lower Chamber writs were issued for the election of members to the seats vacated by Mr. Gladstone, Sir William Harcourt, Mr. John Morley, and others on their acceptance of office under the Crown. Some formal business was transacted in the House of Lords. Late in the evening of the same day Parliament was prorogued.

### *Drinking at Elections.*

Mr. Caine has given notice that in the course of next session he will introduce a Bill to close public-houses and beer-houses on the day of polling in Parliamentary elections.

### *The Visitors in Lunacy.*

There has been presented to Parliament a report of the number of visits made, of patients seen, and of miles travelled by the Visitors in Lunacy between January 1st and June 30th of the present year. These visits are made in pursuance of the provisions of the Lunacy Act of 1890.

## Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

- BRADSHAW, ROBT., L.A.H., L.M.Dub., has been appointed Medical Officer for the Ninth Sanitary District of the Hexham Union.
- BRIGGS, W. P., L.R.C.P. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Aspatria Sanitary District of the Wigton Union.
- BURBIDGE, J. W., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Upper Sanitary District of the Lewes Union.
- COLEMAN, M. O., M.D. Aberd., M.R.C.S., has been reappointed Medical Officer of Health for the Surbiton Urban Sanitary District of the Kingston Union.
- CONNON, C. J., M.B., C.M. Aberd., has been appointed Medical Officer for the Third Sanitary District of the Hexham Union.
- DOYE, EMILY L., M.B. Lond., has been appointed Resident Clinical Assistant to the Holloway Sanatorium Hospital for the Insane, Virginia Water.
- EWART, C. THEODORE, M.D., M.Ch., has been appointed Senior Assistant Medical Officer for the Female Department of the London County Asylum, Colney Hatch, vice W. H. George, deceased.
- FAWSETT, F., M.B. Lond., B.S., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the outlying part of the St. John's Parish of the Lewes Union.
- GIBSON, E. VALENTINE, M.D. Edin., has been appointed Superintendent and Resident Medical Officer to the Victoria Infirmary, Glasgow, vice Dr. Mackintosh, resigned.
- GOW, WILLIAM J., M.D. Lond., M.R.C.P., has been appointed Obstetric Physician to the Royal Hospital for Women and Children, Waterloo-bridge-road, vice W. Duncan, M.D., resigned.
- HARMAN, ALBERT B., M.R.C.S., L.S.A., has been appointed Assistant House Surgeon to the Royal South Hants Infirmary, Southampton.
- HAWLEY, F. H., M.R.C.S., has been appointed Medical Officer for the Blankney Sanitary District of the Sleaford Union.
- JAMES, JOHN, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health for the Rural Sanitary District of the Aberystwith Union, vice Turner, resigned.
- LAING, G. MACKAY, L.R.C.S. Irel., L.R.C.P., L.M., has been appointed Medical Officer and Medical Officer of Health to Ballina Dispensary District, and Medical Attendant R.I.C.
- LEYS, JOHN, M.B., C.M. Aberd., has been appointed Medical Officer for the Norton Sanitary District of the Leak Union.
- NEUBOLT, GEO. PALMERSTON, M.B. Durh., F.R.C.S. Eng., has been appointed Honorary Surgeon to the Liverpool Stanley Hospital.
- PEARSE, F. E., L.R.C.P. Edin., M.R.C.S., has been appointed Medical Officer for the Horsley Sanitary District of the Guildford Union.
- PRICE, W. E., M.B. Durh., M.R.C.S., has been appointed Medical Officer for the Sellershope Sanitary District of the Ross Union.
- SANDFORD, H. V., L.R.C.P. Lond., L.F.P.S. Glasg., has been reappointed Medical Officer of Health for the Rural Sanitary Districts of Bromyard, Hereford, Ledbury, Leominster, and Weobley Unions.
- THOMPSON, P. W., M.B. Toronto, L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer at the Infirmary of the Woolwich Union.
- THORNE THORNE, BERTHOLD B., M.R.C.S., L.R.C.P., has been appointed Assistant House Surgeon to the Royal Portsmouth Hospital.
- WILLS, CHAS., M.R.C.S., has been reappointed Medical Officer of Health for the Southwell and Worksop Rural Sanitary Districts.

## Vacancies.

For further information regarding each vacancy reference should be made to the advertisement.

- BOROUGH OF SUNDERLAND (PORT OF SUNDERLAND).—Medical Officer of Health and Public Analyst. Salary £500 as Medical Officer for the Borough, £20 for the like office for the Port, and £5 as Public Analyst. (Apply to the Town Clerk; Town Hall, Sunderland.)
- CENTRAL LONDON OPHTHALMIC HOSPITAL, 238A, Gray's-inn-road, W.C. House Surgeon. Rooms, coals, and lights provided.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—House Physician for six months. Board and residence and allowance for washing provided. (Apply to the Secretary, Office, 24, Finsbury-circus, E.C.)
- DOCTOR, 2, New Rents, Ashford, Kent.—Qualified Medical Assistant for a Medical Association.
- GENERAL HOSPITAL, BIRMINGHAM.—Assistant House Surgeon for six months. Residence, board and washing provided.
- HOUSE SURGEON, THE LANCET OFFICE, 423, Strand, W.C.—House Surgeon for a small County Hospital near London. Salary £50 a year.
- KENT AND CANTERBURY HOSPITAL.—House Surgeon. Salary £90 the first year, with board &c., rising to £100 the second year.
- KENT COUNTY LUNATIC ASYLUM, Barming Heath, near Maidstone.—Senior Assistant Medical Officer. Salary £250 per annum, increasing by two annual instalments of £25 each up to £300, with furnished quarters, attendance, coal, gas, washing, garden produce and milk.

- KENT COUNTY LUNATIC ASYLUM, Barming Heath, near Maidstone.—Second Assistant Medical Officer. Salary £180 per annum, with furnished quarters, attendance, coal, gas, washing, garden produce and milk.
- LEITH HOSPITAL.—House Physician for six months. Salary at the rate of £50 a year, with board in the hospital.
- LEITH HOSPITAL.—House Surgeon for six months. Salary at the rate of £50 a year, with board in the hospital.
- LEITH HOSPITAL.—Surgeon for the Out-door Department for six months. Salary at the rate of £50 a year, with board in the hospital.
- LONDON FEVER HOSPITAL, Liverpool-road, N.—Assistant Resident Medical Officer.
- LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—House Surgeon for six months. Salary at the rate of fifty guineas per annum, with residence in the hospital, board and washing.
- MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT.—Honorary Assistant Medical Officer.
- M. W., at Shelley's Advertising Offices, 39, Gracechurch-street, E.C.—A qualified Medical Man for the Employes of the Gie Appanto Gold Mining Company, on the West Coast of Africa. Salary £240, all found.
- NOTTINGHAM BOROUGH ASYLUM.—Second Assistant Medical Officer. Salary £100 per annum, with apartments, board and washing.
- ROYAL HOSPITAL FOR SICK CHILDREN, Glasgow.—Assistant House Surgeon. Salary £30, with board and lodging.
- ROYAL SURREY COUNTY HOSPITAL, Guildford.—Resident House Surgeon. Salary £80 per annum, with board, lodging and washing.
- ST. MARY'S HOSPITAL, Paddington, W.—Physician-Accoucheur in charge of out-patients, for five years.
- SUFFOLK GENERAL HOSPITAL, Bury St. Edmunds.—House Surgeon. Salary £100, with board, lodging and washing.
- SUSSEX COUNTY HOSPITAL, Brighton.—House Surgeon. Salary £120, rising to £140 per annum, at the discretion of the Committee of Management, with residence and board in the hospital.
- UNIVERSITY OF GLASGOW.—Assistant Examiner in Medicine. The annual fee for the Examinership is £30.

## Births, Marriages, and Deaths.

### BIRTHS.

- ADAMS.—On Aug. 7th, at Kilcrome, Oxford, the wife of G. D'Arcy Adams, M.D., of a daughter.
- ARNOLD.—On Aug. 13th, at Park-road, Forest-hill, the wife of Ernest C. Arnold, M.B., F.R.C.S. Eng., of a daughter.
- ASKIN.—On Aug. 10th, at Alderton, Woodbridge, Suffolk, the wife of T. Cuming Askin, M.D., of a son.
- LARDER.—On Aug. 14th, the wife of Herbert Larder, Medical Superintendent Whitechapel Infirmary, of a daughter.
- MARRINER.—On Aug. 12th, at Westbourne Tower, Poole-road, Bournemouth West, the wife of W. H. L. Marriner, M.B. Lond., of a son.
- SANDWICH.—On Aug. 15th, at 7, Queen's Gate, S.W., the wife of Fleming Sandwith, of Cairo, of twin daughters.

### MARRIAGES.

- BOLSTER—BELL.—On Aug. 16th, at the Parish Church, Stoke-next-Guildford, Surgeon-Major J. McM. Bolster, F.R.C.S.I., Army Medical Staff, to Violet Mary, elder daughter of the late Arthur Bell, M.B., Surgeon 30th Regiment.
- CHAPMAN—LEWIS.—On Aug. 10th, at the Priory Church, Brecon, Paul Morgan Chapman, M.D. Lond., M.R.C.P. Lond., to Alice Elizabeth, only daughter of the late Rev. J. R. Lewis, of Cascob Rectory, Radnorshire.
- COX—LANE.—On Aug. 10th, at the Church of St. Mary, Woodborough, Wilts, by the Rev. J. Sturton, assisted by the Rev. Mills Robbins, cousin of the bride, Dr. A. E. Cox, of Southport, son of E. B. Cox, Esq., of Nottingham, to Rose Matilda Lane, youngest daughter of E. Lane, Esq., Manor House, Woodborough.
- HORTON—EVANS.—On Aug. 13th, at St. Mary's, Stoke Newington, Wilfred Winnal Horton, M.D., youngest son of William Horton, late of Stanway Manor, Shropshire, to Ellen Fanning (Nellie), youngest daughter of the late Rev. Edward J. Evans, 16, Roseligh-avenue, Highbury.
- OSMOND—ROTHERY.—On Aug. 17th, at all Saint's Church, Pontefract, by the Rev. E. S. Horo, M.A., Edward Bartrum Osmond, M.R.C.S., L.R.C.P., son of Arthur Osmond, late P. and O., to Marguerite Alice, youngest daughter of William Rothery, late of Harrowgate.
- SHEEHY—LANNES.—On July 26th, at St. Bartholomew's Church, Sydenham, W. H. Patmore Sheehy, L.R.C.P. Lond., &c., of Claremont-square, London, to Frances M. S. Lannes, of Castledine, Upper Norwood.

### DEATHS.

- ALLEN.—On Aug. 15th, at Greasley House, Belper, aged 5 years, William Douglas, the darling child of Dr. and Mrs. R. G. Allen.
- CROOKES.—On Aug. 16th, at Augusta-gardens, Folkestone, John Furrar Crookes, F.R.C.S., in his 82nd year.
- HALL.—On Aug. 6th, 1892, at Dalton House, Dalton-in-Furness, Edward Hall, Surgeon, aged 84 years. (Interred at the Dalton Cemetery on the 10th inst.)

N.B.—A fee of 6s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

## Notes, Short Comments & Answers to Correspondents.

*It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.*

*All communications relating to the editorial business of the journal must be addressed "To the Editors."*

*Lectures, original articles, and reports should be written on one side only of the paper.*

*Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.*

*We cannot prescribe or recommend practitioners.*

*Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."*

*Letters relating to the publication, sale, and advertising departments of THE LANCET to be addressed "To the Publisher."*

*We cannot undertake to return MSS. not used.*

### THE STUDENTS' NUMBER.

WE beg to call the attention of the Deans of Medical Schools and the Secretaries of Hospitals to the announcement that the Students' Number of THE LANCET for the session 1892-93 will be published on Saturday, Sept. 3rd. We also invite from them and from the members of the profession information regarding hospitals, institutions for medical education &c.—such particulars as are of importance to students generally, both in connexion with the general medical qualifications, the dental qualifications, and the qualifications in public health. This should be sent to the Sub-editor, THE LANCET Office, Strand, not later than the 25th inst.

### A "TRAVELLER'S TALE."

THE following remarkable illustration of credulity has appeared in the lay press under the title of "A Medical Mystery at Ath." A pottery workman of Rebaix some time ago noticed a swelling in front of the wall of his abdomen, which gradually increased, and which was opened by a leading practitioner at Ath, who discovered a large snail inside the swelling, of a kind common in the gardens round about! The snail has been preserved and is being exhibited by the ingenious and enterprising patient to the townspeople at the small charge of one franc per head. We are certainly inclined to attach more credence to the latter than to the former part of this latest instance of the craze for the marvellous.

*An Enquirer.*—In all cases where there is any doubt as to the cause of death, and especially where the necessary evidence can only be obtained from a medical man, we are of opinion that such should be required by the coroner. In the case mentioned by our correspondent, however, the facts appear so clear that we think the coroner acted with discretion. It must be remembered that the funds at his disposal are the property of the community, whose interests he is bound primarily to serve, provided it be consistent with the demands of justice.

### TREATMENT OF RINGWORM.

*To the Editors of THE LANCET.*

SIRS,—Having recently read several articles as to the treatment of ringworm, and as I have had much experience in the treatment of this affection in India, where it is very prevalent, I would suggest the following—*viz.*: The affected region should first be washed with soap and warm water containing a little carbonate of soda and then well dried. Acetic acid should then be thoroughly applied with a small brush, and in the lapse of about five minutes, when the acid will have soaked into the part, an ointment composed of sixty grains of chrysophanic acid to an ounce of lanoline should be rubbed in. This treatment should be carried out daily for such a period as may be necessary.

I am, Sirs, yours faithfully,

Dublin, Aug. 13th, 1892.

CRAWFORD WARREN, F.R.C.S.I.

### A MEDICAL NOVELIST.

THE prose fiction of all countries owes much to its medically trained contributors. In Great Britain it can point to Tobias George Smollett, Oliver Goldsmith, John Moore (whose once famous "Zeluco" even yet repays perusal), and Charles Lever, to say nothing of Albert Smith and Conan Doyle. France can boast of Eugène Sue, the last of a long line of anatomists and surgeons, and now Italy sustains the part with Leonzio Capparelli, whose death on March 20th last deprived Naples of an able and much-esteemed consultant. Dr. Capparelli was known to the profession as the author of carefully-thought-out and well-written books on debatable points of medicine and surgery, the first of them published in 1856; but not till five years ago (in 1887) did he give the world a specimen of his powers as a novelist. His "Dr. Pietra," the work referred to, is a singularly interesting story, conveying in a vivid yet chastened style the experiences of a life fraught with adventure and dramatic incident. Its success was such that its readers regretted that its author did not cultivate his genius for prose fiction more assiduously; but an agreeable surprise was in store for them. His daughter, the Signorina Clotilde Capparelli, found among his posthumous papers a completed tale entitled "In Illo Tempore," and this she has just edited for the publishing firm of G. Barbèra in Florence. The plot is laid in the fever preserves and criminal substrata of Naples during the worst period of the demoralising reign of Bomba, and it presents the reader with a powerfully drawn picture of the struggle for existence in surroundings characterised by Mr. Gladstone as "the negation of God upon earth." Concurrently with this tale the Signorina Capparelli has sent forth a revised edition of "Dr. Pietra," containing its author's latest improvements on the original text, and both works ought to find many readers among those who have watched the Italian "Risorgimento" from its apparently desperate beginnings to its bright consummation in "Italy one and independent." All who, in view of the International Congress to be held in Rome next year, are desirous of getting up a working knowledge of Italian could not do better than initiate themselves in the attractive and uninvolved periods of Dr. Leonzio Capparelli's two romantic stories.

*Dr. Thurefield.*—The note on the arrow poison of the New Hebrides was taken from *Les Nouveaux Remèdes*, June 24th. M. le Dantec's paper was communicated to the Société d'Anatomie et de Physiologie de Bordeaux, and will doubtless be found in the Proceedings of that body.

*Mrs. F. M. Keeling.*—Our correspondent should consult his medical attendant.

### LOCUM TENENS AND FEES AT INQUESTS.

*To the Editors of THE LANCET.*

SIRS,—Would you kindly give me your opinion, or the general ruling of the profession on the following?

A gentleman whilst acting as locum tenens is called to attend on a case which involves a coroner's inquest, but the locum tenens' time expires one day before the inquest takes place. He, however, calls the next day to see when the inquest is to be held, and being told at 10.30 of that morning, he receives the coroner's order and duly attends and gives evidence. To whom does the fee of one or two guineas belong, the locum tenens or the gentleman who engaged him?

I am, Sirs, yours truly,

Aug 16th, 1892.

M.D.

\*.\* In the first place, whether the principal or his locum tenens shall receive coroners' fees depends upon the terms of agreement. If no special arrangement is made, clearly all fees earned by the locum tenens belong to his employer. The above case, as given by our correspondent, is somewhat different. The engagement having been contracted by the locum tenens during his tenure of duty, the consequences, including the fees, would naturally fall to the principal; but inasmuch as the services of the locum tenens were required after his time had expired, we are of opinion that division of the fees would be an equitable settlement.—ED. L.

### MEDICAL ADVERTISING IN DUBLIN.

A CORRESPONDENT complains that in the higher ranks of medical practice in Dublin there is a disposition to use the fashionable newspaper as a medium of announcing one's whereabouts, whether at home or from home, and he sends us cuttings which support his complaint. *Verbum sapienti*, &c. It is idle to expect the rank and file of the profession to be more exemplary in this respect than their leaders. They have a right to look for an example of reticence and quietness in the upper ranks of practice. Paragraphs, obviously inspired or supplied, giving the movements of medical men are a violation of this spirit, and ought to be rigidly suppressed both in London, Dublin, and elsewhere by all who respect the traditions of the profession.

## THE HOURS BETWEEN CONTERMINOUS EXAMINATIONS.

A CORRESPONDENT writes:—"In the universal system of examination under which this country is at present groaning there is one source of strain which has hitherto escaped notice. I refer to the short interval between conterminous periods of examination. Up to twenty years ago that interval was always two hours. Now it is seldom more than an hour. In the Oxford and Cambridge local examinations, in the examinations of the Scotch universities, of the Civil Service Commissioners and of the University of London it is only one hour. "In the examinations of the University of Cambridge the length of the interval curiously varies. In the pass examination it is one hour; in the examinations of the classical and minor triposes it is an hour and a half; in the examination of the mathematical tripos it alternates between two hours and three hours and a half. On what principle the Cambridge practice is based I do not know; but as a matter of health an interval of two hours after an examination lasting three hours is desirable. An average examinee of either sex requires an hour for fresh air and rest of brain and an hour for food before resuming labour. By inferior candidates the longer interval may be, of course, applied to some process of special cramming—learning by heart parts of a 'crib,' strings of dates, mathematical or chemical formulæ, for instance—which may produce injustice; but the extent to which it would produce this effect would be, I conceive, very trifling. The most experienced coach can seldom forecast with much success the contents of even a pass examination paper. On the other hand, serious injury may result from 'bolting' a hasty meal after crouching for three hours over a desk or table in a more or less impure atmosphere, and then resuming for three hours more the same constrained position."

*L.R.C.P. Lond.* (Warrington).—Our correspondent might address a communication to the Secretary of the Prison Department, Home Office, and to the Permanent Under-Secretary of the Colonial Office respectively.

## "ELECTRIC BELTS."

To the Editors of THE LANCET.

SIRS,—Will you kindly let me ask through your columns any medical men who may have patients who have complaints to make of certain so-called electric belts to communicate with me, if they so desire, in reference to this matter? The public-spirited action of the editor of the *Hawk* deserves the support of our profession.

I am, Sirs, yours faithfully,

A. GEORGE BATEMAN,

Hon. Secretary, Medical Defence Union.

64, Longridge-road, S.W., Aug. 16th, 1892.

## A PAINFUL INCIDENT.

A CORRESPONDENT of the Vienna *Aberndblatt* is responsible for the following statement:—"One morning the medical superintendent of a large lunatic asylum requested an attendant to hand him a pair of scissors. Perceiving something unusual in the aspect and demeanour of his chief, the attention of one of the physicians was drawn to the circumstance, when he was both surprised and alarmed by the announcement from the lips of the superintendent that it was his intention to open the skulls of some of his patients in order to ascertain the exact condition of their cerebral development. It thus became evident that the brain which had been for so long responsible for the medical oversight of the afflicted inmates of his asylum had itself become deranged, a circumstance not unique in the history of neurological research."

*Dr. Allen.*—The circumstances of such cases as that referred to us by our correspondent are so varied and complicated by domestic detail and questions of expediency that the lunacy and other laws—e.g., those relating to the appointment and powers of guardians and trustees—would have to be undergoing a continuous process of amendment if the exceptional points in individual cases had to be legislated for. A suitable guardian and trustee is usually supposed to be able to look after the best interests of his ward on a consideration of all the circumstances of the case.

*A. B.* will see that we have not overlooked the question.

## FUCUS VESICULOSUS.

To the Editors of THE LANCET.

SIRS,—I shall be obliged if any of your readers who have had experience with extract of fucus vesiculosus would give me some information about it. I believe there are some precautions to be used in its administration, but do not know what they are. Does it reduce superfluous fat? Or does it only act like iodine? Is there any wasting of glandular structures produced by it? Has it any influence on the shortness of breath which most stout people complain of? Any information will oblige,

Yours truly,

INQUIRENS.

## MEDICAL ADVERTISING.

A CORRESPONDENT sends us the following cutting from the *Liverpool Daily Post* of the 16th inst., and pertinently suggests that the idea seems to be rather a new one.

"*The Doctors in Liverpool.*—Services will be rendered first three months free of charge. A staff of eminent German and American Physicians and Surgeons have permanently located in Liverpool, corner of Benson-street and Mount Pleasant (entrance on Benson). All who visit these eminent Doctors before September 1st will receive services first three months free. All forms of chronic diseases and deformities are treated, especially male and female weakness, catarrh, catarrhal deafness, &c., but no incurable cases will be accepted. The doctors will examine you thoroughly free of charge; and, if incurable, will frankly, kindly tell you so. The object in pursuing this course is to become rapidly and personally acquainted with the sick and afflicted. Catarrh and catarrhal deafness is positively cured by their American treatment. Office Hours—9 A.M. to 8 P.M.; Sundays, 10 to 12."

Here is another specimen from Saturday's *Huddersfield Examiner*:—

"*Kirkheaton.*—*Medical.*—Mr. Benjamin S. Lockwood, son of Dr. Lockwood of Kirkburton, who passed the final examinations held at Edinburgh in April last, and was granted the diplomas of the Royal College of Physicians, the Royal College of Surgeons, Edinburgh, and Licentiate of the Faculty of Physicians and Surgeons of Glasgow, has, we understand, commenced to practise near the Kirkheaton Railway Station, at the very spot where his grandfather, old Doctor Lockwood, commenced, nearly eighty years ago.—ADVT."

We certainly commend this latter unblushing notification to the attention of the Colleges mentioned above.

*Mr. H. Button* (Manchester).—Our correspondent would probably obtain the information by application to the Emigrant's Information Office, 31, Broadway, London, S.W.

## THE FLY PLAGUE.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of this week is mentioned the plague of fly bites. I am a great sufferer, and cannot sit under my fig tree in summer without suffering this penalty. Last year, whilst in North Wales, I tried iodine soap and then carbolic, but found them useless. The only relief was obtained from a compress of a solution of carbonate of ammonia. If any of my professional brothers would advise me, I should be very grateful.—I am, Sirs, yours obediently,

Aug. 16th, 1892.

A SENIOR F.R.C.S.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.
